Half of the workers had been with their employer eight or more years. Approximately 17% had been employed less than 30 months, only 10% less than 19 months. Of the 335 employee samples, 59.3% had annual incomes of less than $3,500. Of this group, 21% had illnesses causing absences of more than 13 weeks. The council observes that, although the rate of incidence in this income group may not be any higher than that in any other, this represents the largest group of workers and the one least able to meet the cost.

SUMMARY

The ratios established in this preliminary report are based on only a small segment of the total sample, and, even with respect to this group, the total of desirable evidence has not been correlated. Accordingly, any indicated trends may prove to be more apparent than real. In spite, however, of the possible illusory aspects of the evidence before us, there are certain clues that legitimately stimulate our interest and attention. There is an apparent reversal of the absentee incidence among women workers compared to men. While the incidence of absenteeism among women is higher for illnesses of short duration, the ratio is apparently reversed for prolonged illness. Prolonged illness among skilled workers is emphasized and reemphasized to a degree that, if confirmed, will indicate a special investigation in this area. If prolonged illnesses prove to represent 20% of all absences of one week or more and are responsible too for approximately 56% of all time lost during these absences, then prolonged illnesses become a very important problem. If the average duration of some 250 illnesses (51.18 days each) is at all typical, prolonged illness becomes an important factor in terms of appropriate insurance coverage. On the basis of disease classification, diseases of the digestive system occur most frequently, and neoplasms (malignant and benign) and arthritis and rheumatism are the fourth and fifth, respectively, in order of frequency. The more apparent disabilities, such as heart diseases and nervous and mental diseases, are not even included in "the largest percentage of cases." Thus early diagnosis and adequate initial care may contribute to immediate improvements in incidence and duration. The low incidence in the age group 65 and over may necessitate a readjustment of the relative importance of geriatrics in the treatment of prolonged illnesses. The income group that can least afford it (annual incomes of less than $3,500) accounted for 59.3% of the prolonged illnesses.

Certainly the study to date has provided sufficient data, irrespective of the probable ratio adjustments, to indicate that we should look with interest toward the final correlations based on the total sample of 400,000 wage earners. The completed study should give to all interested valid data with which to attack the important problem of prolonged nonoccupational illness among the wage earners of this country.

Measles Encephalomyelitis.—Seventy-seven patients with measles encephalomyelitis were treated at a Milwaukee hospital from 1926 to 1951. The ages of the patients ranged from 5 months to 32 years, but nearly two-thirds were between the ages of 4 and 7. The onset of encephalomyelitis varied from several hours to nine days after the appearance of the morbilliform rash, but in nearly half of the cases it began three to four days after the appearance of the rash. A total of 22 of the patients died, and 15 of these had coma or convulsions or both. The cell count of the spinal fluid varied, but in nearly three-fourths of the patients it was below 90. Although it was over 90 in about half of those who died, the authors do not believe that the cell count of the spinal fluid is of prognostic significance. The protein content of the spinal fluid was increased in 61% of the patients, and the sugar content of the spinal fluid was normal or above normal in all but two of the patients. The leukocyte counts of the blood varied greatly, but in 60% of the patients it was between 9,000 and 18,000. Thirty-six of the 55 survivors answered a follow-up questionnaire, which revealed that 22 had completely recovered; one had choreiform movements for one year with frequent headaches, dizzy spells, and vomiting since that time; one has had persistent tremors involving the extremities; one is epileptic; one has a residual cord bladder, foot drop, and myopia; one is poorly coordinated; three are mentally defective; and six have shown personality changes. The results of necropsy studies on five of the patients are reported. The treatment of measles encephalomyelitis is largely symptomatic. In commenting on the diagnosis, the authors say that a diminished or absent cough reflex was one of the earliest signs of measles encephalomyelitis. It was noted in 74% of the patients. No medication containing codeine should ever be given to depress the cough of measles. The authors have observed patients with codeine intoxication who were hospitalized because of a supposed measles encephalomyelitis with convulsions, lethargy, vomiting, nuchal rigidity, cyanosis, and elevation of temperature. In each instance the spinal fluid findings were normal, and the patient recovered completely within 24 hours after oxygen and helium therapy was instituted.

Acute Toxicity of Carnotite Ore Dust.—Uranium miners are exposed to the dust from carnotite ore in their work. To determine the toxicity of this material the authors exposed animals to carnotite ore dust dispersed in a chamber atmosphere. Mean daily dust concentration was approximately 84 mg. per cubic meter; the average mass median diameter of the chamber dust (particle size) was 1.39 μ. Rabbits and one goat were exposed for 131 exposure hours during 31 calendar days; rats were exposed for 137 exposure hours during 32 calendar days. Ninety-two per cent of the rabbits died; 10% of the rats died. The goat survived. Toxicity was further evidenced in the rabbits by weight loss, by sharp elevation of blood nonprotein nitrogen and urinary protein levels, and by renal tubular damage; in the rat by weight loss, by renal tubular damage, and by gross lung damage; and in the goat by renal tubular damage. Mean deposits of uranium and vanadium in the rat lungs (370 and 146 μg per gram of fresh tissue, respectively) were 50 to 300 times as great as corresponding amounts in the femur and kidney. The same was true for uranium in the tissues of rabbits and the goat. Deposits of uranium and vanadium in the rat lungs increased linearly with exposure hours. The only hematological finding of interest was basophilic stippling in two of the rabbits. From the results of this experiment the authors conclude that carnotite ore dust inhaled by animals under the conditions of this experiment is highly toxic to the rabbit, moderately toxic to the rat, and slightly toxic to the goat. The toxicity is characteristic of uranium poisoning and in degree closely resembles that of uranium trioxide.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

more. After one year only nine patients continued to take the drug, and only five of these nine continued to maintain a significant reduction in mean blood pressure (excess of 20 mm., or below 150 mm. systolic and 100 mm. diastolic). In the remaining four side-reactions occurred when the drug is given in doses that will reduce the blood pressure. Eleven of 20 patients had proved unresponsive to hexamethonium alone in gradually increasing doses beginning with 250 mg. four times daily. In nine a significant blood pressure reduction was obtained with hexamethonium alone, but it was felt that better stability and/or additional reduction could be obtained with combined hexamethonium and hydralazine therapy. After hydralazine was added to the hexamethonium regimen, no significant reduction in blood pressure occurred in 7 of the 11 patients who failed to respond to hexamethonium alone, but 4 did show a significant response to combined therapy. In seven of the nine patients who had obtained some response to hexamethonium alone, there was a significant additional response when hydralazine was added, but in the two others there was no additional response. Of 32 patients who had proved unresponsive to hydralazine alone all but six showed a significant reduction in blood pressure following the administration of hexamethonium. Hydralazine, apparently reduces the blood pressure through a central vasodepressor action. At the same time it stimulates (centrally) the sympathetic nerves to the heart, causing tachycardia and increased cardiac output. During continued oral therapy the cardiac stimulant effect is lost long before the hypotensive effect. Eventually tolerance to the hypotensive response also develops. The cardiac stimulant effect is blocked off if hexamethonium has been given in amounts adequate to produce ganglionic blockade. Hydralazine reinforces the hypotensive effect of hexamethonium. Although hydralazine increases renal blood flow in patients with and without renal damage, glomerular filtration is not increased. The combined use of hexamethonium and hydralazine may produce a dramatic and sudden reduction in blood pressure, which in the presence of severe renal damage may be associated with a significant reduction in glomerular filtration rate and renal excretory function. Therefore, careful evaluation of changes in renal excretory function by repeated blood urea nitrogen determinations is necessary when treating hypertensive patients who have renal damage.

Pneumococcic Meningitis.—Alexander and associates review 102 cases of pneumococcic meningitis seen at the Philadelphia General Hospital during the past decade. Autopsy records were available in 68. Factors influencing the mortality rate were studied. The prognosis for recovery was more favorable in the 1 to 15-year-old group than in other age groups. The mortality rate does not appear significantly influenced by the presence of bacteremia or coma, but the rate is significantly higher when the meningitis is secondary to pneumonia than when the sinuses, middle ear, mastoid, or head trauma are involved. Pneumococci of types 4 and 12 were found in a significantly greater number of cases and were associated with a greater number of deaths than other types. Penicillin alone, or penicillin in combination with sulfonamides, is more effective in reducing the mortality rate than are sulfonamides alone or the sulfonamides in combination with type-specific anti-pneumococcus serum. The efficacy of penicillin is probably influenced by the speed with which therapy is begun and the intensity of the therapy. Intrathecal administration of penicillin does not seem necessary when moderate intramuscular doses of penicillin (800,000 to 2,400,000 units) and oral doses of sulfonamides (4 to 6 gm.) are given daily, or massive doses of penicillin (1,000,000 units every two hours) are administered intramuscularly. The rationale for the combined therapy is the demonstrated synergistic activity of penicillin and the sulfonamides against the pneumococcus. The rationale for the massive penicillin therapy is the ability to establish penicillin concentrations in the cerebrospinal fluid that are inhibitory for the pneumococcus. In view of the encouraging results obtained with these therapeutic schedules, surgical intervention should be confined to cases in which the response is not as anticipated.

Cortisone in Shoulder-Hand Syndrome Following Myocardial Infarction.—Cortisone was employed in the treatment of 17 patients in whom the shoulder-hand syndrome developed as a complication of acute myocardial infarction. In all these patients previous treatment with physical therapy, manipulative therapy, or local and stellate ganglion blocks was without significant effect. Cortisone produced complete relief of signs and symptoms in five patients, marked improvement in eight, moderate improvement in three, and no significant response in one. The striking feature of the treatment was its dramatic effect in the relief of pain, often within 24 to 48 hours. In addition, there was concomitant but often less marked improvement in the range of motion at affected joints. Vasomotor disturbances were also rapidly influenced, with decrease or disappearance of edema and improvement in temperature, color, and sudomotor activity of the hand. In patients responding favorably, there was no recurrence of symptoms after discontinuance of treatment. No thromboembolic complications were encountered in this series. These and previous observations fail to confirm the serious risk of vascular complications that is claimed to result from the use of this drug. Cortisone appears to be a safe and extremely effective form of treatment in refractory cases of the shoulder-hand syndrome complicating acute myocardial infarction.

Treatment of Chemical Burns of the Eye.—Kuhn, who treated over 300 cases of chemical and thermal burns of the eye with calsulfhydryl (Hydrosulfosol), reported that pain was controlled, healing was more rapid, visual restoration was accelerated, permanent disability was reduced, and there were fewer indications for conjunctival flaps. Calsulfhydryl has also been reported to be a valuable adjunct in the treatment of ocular injuries caused by anhydrides and detergents. To verify those reports Harley studied the effects of calsulfhydryl in a total of 157 rabbit eyes in which burns had been produced with various chemical agents, including strong acids, strong alkalis, anhydrides, and specific agents designed for enzyme inhibition. In 53 pairs of rabbit eyes in which corneal lesions were produced with various chemicals, results showed that the calsulfhydryl-treated eye was neither better nor worse than the control, untreated eye. With only one chemical, iodoacetate, did calsulfhydryl, in three paired experiments, give consistently better results than those in the control eye. This was to be expected, since calsulfhydryl supplies sulfhydryl radicles, which combine with iodoacetate, thus preventing iodoacetate from inhibiting tissue enzymes and denaturing tissue protein. The author feels that the chief sphere of activity for sulfhydryl compounds is in lesions produced by specific enzyme-inhibiting agents that combine chemically with the sulfhydryl radical. Studies of lesions caused by specific chemicals should be undertaken for further evaluation of this compound. Present day concepts of the treatment of ocular burns are outlined and modified in the light of the observations described. The technique of "denudation of the cornea" advocated by McLaughlin has certain advantages, especially in alkali burns. Cortisone appears to be of definite value in inhibiting fibroblastic proliferation and corneal vascularization.

*Hypersensitivity to Protamide: Report of Case. A. S. Zdanis.—p. 267.

Hypersensitivity to Protamide.—Protamide, a proteolytic enzyme prepared from hog stomach, has been in use for over 10 years in the treatment of tabes dorsalis, because of its ability to relieve the lightning pains of tabes in a high percentage of cases. Lately, this drug has been used in the control of the pain and itching occurring in herpes zoster. In the case of herpes zoster presented here there occurred a severe systemic reaction immediately following the injection of the recommended dose of protamide. Skin tests performed later seemed to indicate a hypersensitivity in comparison with the results in six other persons. It is evident that this drug should be used with caution. A fraction of the original dose should be given at first, in order to reduce the severity of the reaction if one should occur.

Excretion of Polyvinyl Pyrrolidone.—The excretion rate and the subsequent distribution in the body of retained portions of the proposed plasma extender polyvinyl pyrrolidone were studied in four patients with advanced cancer who required hydration by the intravenous route. Determinations were made by using C^{14} labeled polyvinyl pyrrolidone (PVP-macrose) as a tracer. About one-third was excreted in the urine in the first six hours, one-half in the first 12 hours, and about two-thirds in the first 24 hours. Small amounts were excreted in the feces. Each of the four patients died within from two to eight days following the administration of polyvinyl pyrrolidone, and necropsies were performed on all. The unexcreted portion of polyvinyl pyrrolidone showed a distribution consistent with that of any inert material of large molecular size, with the greatest concentrations tending to occur in the kidneys, lungs, liver, spleen, and lymph nodes. No histological evidence of polyvinyl pyrrolidone itself, or damage caused by it, was demonstrated. The authors emphasize that nothing can be concluded from these data about the effectiveness of polyvinyl pyrrolidone-macrose as a plasma extender or about possible physiological damage resulting from its use.

Inclusion Pneumonitis in Adult.—The occurrence of severe and distinctive pneumonitis due to the salivary gland virus is reported in a 54-year-old woman and in a 28-year-old man. Biopsy of the lung permitted the diagnosis to be made during life. Histopathological examination of lungs in both cases revealed essentially similar features. The lung parenchyma was greatly altered. The cells lining the alveoli were large and prominent, varying from cuboid to swollen polyhedral forms with round vesicular nuclei. This reversion to a "fetal type" of lining cell was prominent in all areas. Many of these cells were exfoliated into the alveoli or lined up around the septal walls, and showed both giant nuclear inclusions and multiple cytoplasmic inclusions. All the alveoli were distended by large plugs of esosinophilic protein coagulum with only threads of fibrin that stained blue with Weigert's stain. Plastered against the septal walls and spreading through pores of Cohn were dense membranes, which stained intensely with Sudan black B and periodic acid (Schiff) and metachromatically with toluidine blue. The inflammatory cells, observed principally in the septal walls, were numerous and predominantly of the large mononuclear or plasma cell variety. The mononuclear infiltrate and the hyaline membrane suggested a virus infection. The alveolar walls were greatly widened by fluid and nodal collections of monocytic cells. Frank intra-alveolar hemorrhage was focal but extensive in distribution. In the male patient, the mononuclear response was so intense that it simulated a lymphomatous infiltration; in addition a necrotizing arteritis was observed, the cause of which is obscure. It is suggested that the fulminating salivary-gland-virus disease in adults may result from altered susceptibility induced by the action of antimetabolites.

Effect of Heparin in Effort Angina.—Graham discovered that angina pectoris is sometimes relieved during heparin therapy while he was investigating the effects of heparin on the concentration of the serum lipoproteins (S_f 12-20 and 20-100). The efficacy of heparin in effort angina has since been corroborated by some and denied by others. Rinzler and coworkers report observations on 18 patients with unequivocal evidence of coronary artery disease and with a history of chest pain produced by effort (usually walking) and relieved promptly by rest or nitroglycerin. The patients were observed for approximately two months prior to heparin administration. To eliminate the factor of unconscious bias the double blind-fold method was employed. This meant that the study was conducted by a team, and that not merely the patient but also the physicians who questioned and examined them, injected the solutions, and later assessed the data were unaware of the nature of the coded solution given to any particular patient. The patients were paired with respect to age, sex, duration of effort angina, and incidence of myocardial infarction, and were then divided at random into two parallel series. Heparin was administered to one group of nine patients while the placebo was given concurrently to the other group of nine twice weekly over a period of eight to nine weeks. Each dose of heparin was 100 mg. The effect of the injections on effort angina was judged by the daily report card system (the patient's day-to-day evaluation of cardiac pain) and by the average number of nitroglycerin tablets used per week. Electrocardiograms and ballistocardiograms were taken before and after the course of injections. The results, based on the analysis of 1,883 report card days recorded by 18 patients, show that heparin has no greater effect than a placebo in the control of effort angina. A comparison of the levels of serum lipoproteins of the S_f 12-20 and S_f 20-100 classes showed no significant change in concentration after six weeks of heparin or placebo therapy. Side-effects consisted of dizziness and headache; their incidence was slightly higher in the placebo than in the heparin group.

Bethanechol Chloride in Chronic Glaucoma.—The urethane of bethanechol (Urecholine) chloride is a cholinergic agent simulating acetylcholine in its action, but it is not as rapidly destroyed by cholinesterase. It combines the two components that individually render methacholine (Mecholyl) and carbachal (Doryl) more stable than acetylcholine in tissues. It is possibly the longest acting miotic and the most potent of this choline series. Even in dilute solutions, it can be autoclaved at 120 C for 20 minutes without loss of potency. Its use in ophthalmology has been limited, but it has been used widely in postoperative urinary retention, abdominal distention, gastric retention, and megacolon. Because of its potential value in the medical therapy of glaucoma, it was tried by Frisch and Leopold in treatment of chronic glaucoma. Comparisons were made with other cholinergic agents, namely, both the nitrate and hydrochloride salts of pilocarpine, carbachol, and physostigmine, an anticholinesterase. Bethanechol chloride was tried also in several cases of glaucoma secondary to venous thrombosis and in several cases of absolute glaucoma. The concentration of the drug employed was 1% in benzalkonium (Zephiran) (1:10,000). It was applied by the instillation method, as were the other drugs with which it was compared. The authors conclude that in a 1% concentration this drug approximates pilocarpine (1 or 2%) and carbachol (0.75%) in the treatment of chronic noncongestive glaucoma. In the 1% concentration the drug was not effective in glaucoma secondary to venous occlusion. The authors list the following disadvantages of this drug: It caused a mild allergic reaction in one of 42 eyes. There is the possibility of bronchoconstriction in asthmatic persons, but no instance of this occurred in this series, and ciliary spasm may occur but it is not marked. The drug appears to be an effective and safe miotic that may possibly be useful as a substitute for pilocarpine or carbachol in chronic glaucoma.

Present Status of Goniotomy.—Barkan believes that goniotomy is indicated in all bilateral and unilateral cases of congenital glaucoma in which increased pressure is the result of obstruction of the angle by persistent embryonic tissue or false anterior insertion of the iris, provided that Schlemm's canal has not been obliterated by prolonged distention of the globe. This includes the majority of cases of congenital glaucoma. A total of 178 eyes with congenital glaucoma were subjected to goniotomy between 1936 and 1952. The results of the operations on the first 76 eyes were previously reported. Goniotomy preserved useful vision in most of the 178 eyes with infantile glaucoma. In 129 eyes pressure was normalized and vision maintained or restored. In those cases in which the diagnosis was made early, the operation insured vision sufficient to permit the child to attend ordinary schools. The operation was unsuccessful in 26 eyes. In the last three years, by virtue of improvements and simplifications in technique, it has been possible to operate with the glass under gonioscopic control on eyes in which this procedure would formerly have been impossible. This technique is described. A case of glaucoma associated with aniridia was operated on successfully by goniotomy. While no conclusion can be drawn from an isolated case, the author feels that the good result in this case encourages the hope that goniotomy may in the future prove effective in similar cases. The author pleads for the early diagnosis of congenital glaucoma and for prompt, adequate operation by goniotomy. The operation should be performed under gonioscopic control whenever possible. If, soon after its onset, increased intraocular pressure is normalized by goniotomy, transparency of the cornea is almost completely restored and maintained, and vision is afforded an opportunity to develop. The urgency of prompt relief of the increased pressure is stressed.

High Energy Electrons for Superficial Malignant Lesions.—There has been an increasing interest in the possibility of using artificially accelerated high energy electrons in radiation therapy. It has been recognized that the biological effect of high energy cathode rays and roentgen rays should be similar, since the ionization that they produce in tissue is mostly the result of electron interaction. Similar doses of electrons and roentgen rays were required to elicit a specific biological response in micro-organisms. The superiority of cathode rays for the treatment of superficial malignancies arises from the unique localization of its ionizing energy below the absorbing surface. The authors compare the distribution obtained with 2.5 mev. cathode rays with that of 100 kv. roentgen rays with standard factors of filter and distance used in superficial therapy. The dosage distribution in depth obtained from a radioactive strontium (Sr^{90}) beta ray source using a typical surface applicator is also shown. So far only four patients have been treated with the cathode rays, which were produced by an electrostatic accelerator of the Van de Graaff type insulated with compressed gas designed at the Massachusetts Institute of Technology. These patients had extensive skin lesions no longer amenable to other forms of treatment, including roentgen therapy. Two of the four patients had pathologically and clinically diagnosed mycosis fungoides and two atopic dermatitis. Blood studies carried out during treatment revealed no changes indicative of damage to the hematopoietic system. In the two patients with mycosis fungoides most lesions entirely disappeared, and, at the time of writing, their skin, while still pigmented as a result of disease, appeared normal. The two patients with atopic dermatitis improved only slightly. The authors feel that cathode rays will be efficacious in the therapy of a number of benign skin lesions, including keloids, verrucae, industrial dermatoses, and tinea capitis. Cathode rays should be helpful in the treatment of localized malignant lesions, such as basal cells and squamous cell carcinoma. They appear to be especially applicable to generalized superficial malignant lesions such as mycosis fungoides.

*Raynaud's Disease and Raynaud's Phenomenon. A. L. Scherbel.—p. 266.

Raynaud's Disease and Raynaud's Phenomenon.—Raynaud's phenomenon, a functional vasospastic disorder, is frequently a manifestation of serious systemic disease. It must be distinguished from Raynaud's disease proper, which is characterized by the following criteria established by Allen and Brown: (1) episodes of Raynaud's phenomenon excited by cold or emotion; (2) bilaterality of Raynaud's phenomenon; (3) absence of gangrene, or if present, its limitation to minimal grades of cutaneous gangrene; (4) absence of any primary disease that might be causal; and (5) persistence of symptoms for two years or longer. Since patients with Raynaud's disease have no serious organic vascular disease, they should be reassured. Progression of the disease is possible, however, and examination at regular intervals is advisable. The patient should be advised that the body, as well as the extremities, must be sufficiently warm. Since smoking produces vasoconstriction and reduces skin temperature, patients who smoke excessively should be advised to abstain. Conservative therapy is sufficient if the disease is mild and nonprogressive; sympathectomy is the most satisfactory treatment if symptoms increase in severity or complications develop. Discussing the conditions that may be associated with secondary Raynaud's phenomenon, the author mentions among others: thromboangiitis obliterans, arteriosclerosis obliterans, pneumatic hammer disease, generalized scleroderma, periarteritis nodosa, and conditions resulting from various traumas, such as gun-shot wounds, fractures, severe sprains, and bruising injuries near large blood vessels. Occasionally a cervical rib or the shoulder-hand syndrome are associated with neurovascular symptoms. Diseases of the nervous system that may be complicated by secondary Raynaud's phenomenon are anterior poliomyelitis, progressive muscular atrophy, myelodysplasia, spina bifida, spinal cord tumors, protruded intervertebral disks, and head injuries. Arsenic intoxication may also be associated with secondary Raynaud's phenomenon. Whenever Raynaud's phenomenon is secondary to some other disease, treatment should be directed against the underlying disease.

Bed Rest in Minimal Pulmonary Tuberculosis.—From 1927 through 1946, 589 patients with active, uncomplicated minimal tuberculosis were treated by modified bed rest alone at Trudeau Sanatorium, New York; they were followed for 5 to 25 years. On this regimen the patient spent approximately 20 to 21 hours per day reclining in bed or on a chaise longue, eating meals in an adjoining room, and had full bathroom privileges. Because the mortality due to tuberculosis was quite low (5% in 20 years), rates of progression of tuberculosis were used to measure the effectiveness of the treatment. The term "progression" is defined as any definite increase of disease or development of cavity interpreted from the chest roentgenogram. Each search for a possible correlation of the rates of progression and various factors such as age, sex, extent of disease, was first made by using "five-year progression (any) rates." The "five-year progression (any) rate" was the proportion of patients having at least one progression, as defined, during residence at the sanatorium or during the first five years after discharge. Since contact with 26 of the 589 patients was lost in less than five years after discharge, only 563 remained available for analysis by this method. Of these 563 patients, 201 (35.8%) at the end of the 20 year follow-up have had at least one known progression. The condition of 154 (27.6%) progressed at some time during the 20 years to advanced disease, i. e., beyond the minimal classification. The chance of recurrent progression among those who had a primary progression was approximately the same as the chance of a first progression in the entire group. The age of the patient and the extent of the disease were observed to be related to the incidence of later progression. Sex, location of disease, duration of modified bed rest, duration of sanatorium residence, and duration of time away from full employment had no demonstrable relationship to later progression. Despite the low tuberculosis mortality, progressions and recurrent progressions of minimal tuberculosis produced a total loss of economic usefulness of sufficient magnitude to justify a continued search for a more dependable form of treatment for minimal tuberculosis than modified bed rest.

Bed Rest in Tuberculous Pleurisy with Effusion.—In 194 cases of primary tuberculous pleurisy with effusion, with and without minimal pulmonary infiltration, treatment consisted of modified bed rest at the Trudeau Sanatorium, New York. The patients were followed for 5 to 25 years after discharge. Of the 194 patients, 10 died of tuberculosis, a cumulative tuberculosis mortality of 5% in 20 years; the cumulative rate of reactivation of tuberculosis was 23.7% within the same period. Most of the initial reactivations of tuberculosis occurred within five years following discharge. Contact was lost with 27 (14%) of the 194 patients. Of the remaining 167 patients, 142 (85%) were well and able to work 5 to 25 years after discharge. Evidence suggested that the presence and extent of minimal pulmonary infiltration is related to the rate of reactivation of tuberculosis during the first five years after discharge. Other factors, which were apparently unrelated to the incidence of reactivation of tuberculosis, were as follows: age, sex, severity of symptoms, presence or absence of Mycobacterium tuberculosis in sputum and pleural fluid, and duration of modified bed rest and sanatorium residence.

Comparison of Isoniazid, Streptomycin and Isoniazid, and Streptomycin and *p*-Aminosalicylic Acid in Pulmonary Tuberculosis.—Of 649 patients with pulmonary tuberculosis susceptible to streptomycin who were treated and observed for 28 weeks, 203 were given 1 gm. of streptomycin twice weekly plus 10 to 12 gm. of *p*-aminosalicylic acid daily; 219 received 1 gm. of streptomycin twice weekly plus 150 to 300 mg. of isoniazid daily; the remaining 227 patients received 150 to 300 mg. of isoniazid alone daily. Thirteen of the 649 patients died during the 28 weeks of observation: three from the streptomycin-*p*-aminosalicylic acid group, two from the isoniazid group, and four from the streptomycin-isoniazid group died of tuberculosis, while three in the last-named group died of myocardial infarction, and one of cerebral hemorrhage. Improvement, as evidenced by roentgenographic, clinical and laboratory findings, continued with all three treatment regimens. At the end of 28 weeks, 47% of the patients in the streptomycin and *p*-aminosalicylic acid group, 54% of those in the streptomycin and isoniazid group, and 51% of the patients in the isoniazid group demonstrated at least a moderate degree of roentgenographic improvement; approximately an additional 25% showed slight improvement. Thus the results of treatment were essentially similar on the three regimens.

Wound Disruption.—After reviewing the physiology of wound healing, Schiebel and Creech discuss the etiological factors in disruption, emphasizing that delayed wound healing and increase in intra-abdominal pressure postoperatively are the most important of these factors. They review the records of 23 cases seen in a community hospital of 225 beds over a period of 10 years. The operations were performed by several surgeons, but the technique of wound closure was usually the same, with the use of continuous surgical catgut in the peritoneum and interrupted sutures of cotton or silk in the fascial layer. Disruption followed cholecystectomy in five cases, appendectomy in three cases, and malignant lesions were present in three cases. Anemia was present in two cases and obesity in one. Intestinal obstruction and/or abdominal distention complicated eight cases. Retching or postoperative coughing was a definite factor in causing disruption in eight cases. There were two operations on the colon. Infection was not important. When dehiscence is discovered, any eviscerated bowel should be covered with a sterile dressing and the abdomen taped to prevent further disruption. Morphine is given and a gastric suction tube is inserted. The stomach is aspirated and the tube is left in place. Dextrose is given intravenously. If indicated before or during operation, transfusions of whole blood are given. If the patient's condition permits, the wound is resutured at once. In the 23 cases observed at their own hospital, closure of the wound on the day of disruption seemed to have no influence on the mortality, since all five patients who died had been treated in this way. The mortality rate is highest after colon operations and in patients with cancer. The chief causes of death are pneumonia and peritonitis, but pulmonary and myocardial infarction are found in some patients who come to autopsy.

Cyclospasmol in Peripheral Vascular Disease.—A new vasodilator drug, Cyclospasmol (the 3, 5, 5-trimethylcyclohexanol ester of mandelic acid) was given a therapeutic trial over 12 to 18 months in 33 men and 17 women between the ages of 16 and 76. Of the 50 patients, 28 had arteriosclerosis obliterans, 5 had thromboangiitis obliterans, and 17 had various vasospastic disturbances. The drug was administered orally, starting with an initial dose of 100 to 200 mg. daily, while subsequently doses up to 600 to 1,000 mg. were given in advanced cases. No toxic or important undesirable side-effects were observed, even after prolonged administration. Of the 28 patients with arteriosclerosis obliterans, 17 (61%) obtained good results and 7 (25%) moderate results; and 4 (2 of whom had familial hypercholesterinemia) were therapeutic failures. Three of the five patients with thromboangiitis obliterans obtained good results, one was moderately improved, and one was a therapeutic failure. Eight of the 17 patients with vasospastic disturbances had excellent results, 4 were moderately improved, and 5 were therapeutic failures. The criteria of success were not only the clinical course but also objective symptoms, such as claudication time, healing of extensive gangrenous lesions, and skin temperature. The angina pectoris that was frequently associated with arteriosclerosis obliterans seemed to be favorably influenced by Cyclospasmol. During six months various patients with angina pectoris were, therefore, given alternately placebo tablets, 300 to 600 mg. of Cyclospasmol, 100 to 300 mg. of crystalline visammin (khellin), and combined Cyclospasmol and visammin tablets (one tablet containing 50 mg. of Cyclospasmol and 25 mg. of visammin three times daily). The combined tablets caused disappearance or a considerable decrease of anginal symptoms, but the treatment has been too short to warrant definite conclusions. As a result of his experience, the author states that Cyclospasmol is a valuable asset in the treatment of peripheral vascular diseases.

Dermatitis Caused by Inhalant Antigens.—In over 20 years of practice in allergy Diamond was frequently confronted with eczematous dermatoses of obscure allergy. In recent years he observed an increasing number of patients who presented themselves primarily for the treatment of atopic dermatitis, and many of them came on the recommendation of older patients with respiratory complaints whose concomitant dermatoses had responded to treatment with antigens involved in the respiratory disorders. Of 236 consecutive new patients seen by the author from January, 1949, to July, 1952, 179 complained primarily of respiratory tract symptoms. Among these, the diagnosis of a concomitant atopic dermatitis was made in 23 instances (9.5% of the total). In the remaining 57 patients of this series the primary complaint was dermatological; 23 of these patients had atopic dermatitis, and 7 of the 23 also had bronchial asthma, allergic rhinitis, or hay fever. The author presents case histories that illustrate the improvement of atopic dermatitis coincidentally with the immunologic treatment of hay fever, bronchial asthma, or allergic conjunctivitis. From slowly accumulating experiences the author deduced the following concepts: 1. A high incidence of eczematous dermatoses is seen among subjects with allergic respiratory disease, such as hay fever and bronchial asthma. 2. The dermatoses often improve coincidentally with the treatment of the respiratory complaints by means of individually adjusted and, as a rule, small, doses of extracts from the antigens involved in the respiratory disorder. 3. Exacerbations of dermatitis caused by inhalants are observed following the injection of extracts from dust, pollens, molds, etc., for the purpose of testing for therapy. 4. Favorable results are obtained in the treatment of such skin lesions with concentrations of dust, pollens, or mold extracts in much smaller doses than those used in the treatment of respiratory complaints.

Management of Malignant Hypertension.—According to Sokolow and Schottstaedt, the prognosis of malignant hypertension is no longer hopeless, particularly if modern treatment is instituted prior to the stage of severe renal impairment. Treatment should be instituted promptly after adequate investigation has excluded the presence of reversible conditions such as pheochromocytoma and unilateral atrophic pyelonephritis. The most effective medical management at the present time appears to be the use of hexamethonium by parenteral injection, combined with the oral administration of hydralazine, low sodium diet, and adequate attention to the emotional needs of the patient. The newer veratrum alkaloids, such as protoveratrine, are also of value. An adequate trial of hexamethonium given subcutaneously by the authors to 17 patients with malignant hypertension resulted in reversal of papilledema and clinical improvement in 10, including 2 with chronic glomerulonephritis and 2 with chronic pyelonephritis; in these 4 patients the creatinine clearance rates were between 33 and 57 cc. per minute prior to therapy. In patients whose creatinine clearance rates were less than 30 cc. per minute, renal failure progressed despite hexamethonium therapy. There were two patients in whom the addition of 300 mg. daily of hydralazine administered orally to 70 mg. of hexamethonium twice daily subcutaneously was of striking benefit after only modest improvement resulted from parenterally administered hexamethonium. A combination of hexamethonium given orally and hydralazine orally may prove to be as effective as the combination suggested above, but, in view of the results reported by Kilpatrick and Smirk, this remains to be proved. The patient should be under close medical supervision, preferably in the hospital, when the treatment with the new antihypertensive agents is instituted, and great care should be exercised to avoid hypotensive reactions. Prior to January, 1950, bilateral radical lumbodorsal sympathectomies were performed by the authors on eight patients. In six of these patients reversal of papilledema occurred. Death in uremia occurred in only one patient, who had subacute glomerulonephritis. The other five deaths were due to cardiac or cerebral lesions. Two patients are living 43 and 57 months after diagnosis. Of four other patients with malignant hypertension on whom sympathectomies were performed after January, 1950, two who showed temporary improvement and reversal of papilledema died one year and 22 months, after the operation. The other two patients had reversal of papilledema and were alive and well 23 months and 6 months after the surgical intervention. It is apparent that sympathectomy in the early stages of malignant hypertension in patients with adequate renal function is an effective method of treatment; the accelerated phase of the disease is reversed in 30 to 50% of the patients.

Lupus Erythematosus Disseminatus.—In the past 15 years, 44 patients (group A) with lupus erythematosus disseminatus were observed at Columbia University College of Physicians and Surgeons and at the Presbyterian Hospital in New York and data of 279 additional patients (group B) were collected from the literature of 1948 to 1952. Female patients made up 98% of the first group and 85% of the second group. The age of onset varied from 5½ to 60 years in group A, but the peak incidence in both groups was in the second, third, and fourth decades, with an approximately equal distribution in each decade. Only 3 of the authors' 44 patients had a family history of rheumatic disease, while this feature was not evaluated in the cases collected from the literature. Arthritis and arthralgia were common and were noted in 77% of group A and in 68% of group B. Cardiac manifestations were seen frequently in both groups. Respiratory tract involvement was less frequently observed in both groups. Transient chest pain was a prominent complaint, though less frequently accompanied by objective findings. Generalized enlargement of lymph nodes was noted repeatedly in patients of both groups. Gastrointestinal complaints were prominent in 36% of the group A patients, and in a somewhat smaller percentage of the group B patients. Peripheral and facial edema was present more frequently in group A than in group B. Raynaud's phenomenon was observed in 16% of the group A patients, while the incidence of these changes in group B was low. Eyeground changes were infrequently noted in group B, but occurred in 9 (20%) of the 44 patients. Anemia was common and was frequently apparent at the onset in both groups. Elevation of the erythrocyte sedimentation rate to more than 50 mm. in the first hour was present in 86% of the group A patients and in an approximately similar percentage of group B. Albuminuria of greater than 1+ was seen in 70% of the group A patients, and in 58% of group B. Electrocardiographic changes indicative of myocardial or pericardial disease were observed in both groups. Of the 44 group A patients, 31 died and 13 (30%) were alive more than five years after the onset of the disease; 22% of 103 patients who had been followed for more than five years were alive in group B. As a result of these observations, the authors state that, while the prognosis of lupus erythematosus disseminatus is unfavorable, approximately 22% of the patients remain alive for periods in excess of five years. At least 6 of the 44 patients have been relatively asymptomatic for periods ranging for from 4 to 20 years. This fact must be considered in an evaluation of a therapeutic regimen. Although the usefulness of corticotropin (ACTH) and cortisone in the palliative therapy of the patients with lupus erythematosus disseminatus cannot be denied, it will remain for further long-term studies to determine the effect of these hormones on the life spans of these patients.

Postural Vertigo Relieved by Traction of Cervical Spine.—In a reported group of 43 patients with chest pain as the chief complaint, a history of vertigo was elicited in 21. In some, this symptom had recurred over a period of years. Generally it was mild and transient, but in several it was severe and, at times, incapacitating. In addition to chest pain and vertigo, other manifestations, such as suboccipital headache, shoulder girdle pain, limitation of head rotation, spasm and tenderness of the posterior cervical muscles, and tenderness over the cervical or dorsal spine and in the parasternal region, were often present. Detailed reports are presented of seven patients between the ages of 38 and 70 years with vertigo as a major complaint. The most striking feature was the precipitation of the attack of vertigo by sudden turns of the head and neck from long-maintained positions, and almost regularly by the act of getting out of bed in the morning. The attacks of actual vertigo were usually of very short duration, lasting less than a minute and often only a few seconds, but they recurred frequently. After some bodily activity, such as dressing or walking, the tendency to recur was lessened. An unsteadiness of gait persisted in most instances a few minutes, in some for hours, and in a few for days. Nausea and occasionally vomiting accompanied the vertigo. In several instances attacks were reproduced by having the patient get up suddenly from the examining table. Most of these attacks were interrupted and recurrences prevented or lessened by cervical traction and exercises. The manual method in the reclining position and the overhead method of Hanfling were used. Evidence that this vertigo is of cervical origin may be summarized as follows: (1) the striking response to traction and exercises, as shown by the immediate effect on the attack itself and the prevention of recurrences; (2) the close relation of the attacks to a prolonged position of the cervical spine, the effect of sudden changes from this position, and the reduction of attacks after bodily activity has been resumed; (3) the high incidence of the other manifestations of the cervicodorsal radiculitis; and (4) the absence of clinical manifestations of intracranial disease, cerebral arteriosclerosis and disturbances of the labyrinth. The radicular distribution of changes in skin sensation in patients with shoulder girdle and chest pain in this condition suggests nerve root involvement, and a similar upper cervical mechanism may be assumed as the basis for the vertigo, which is effectively treated by appropriate orthopedic measures.

Treatment of Drug Addiction.—In a trial on 63 psychiatric patients it had been found that mephenesin (Tolserol) reduced or abolished gross tremor, relieved severe anxiety, and calmed hypomanic patients. In two drug addicts the new compound appeared to abolish the withdrawal symptoms. This report deals with observations on 20 drug addicts to whom the new drug was given as an adjunctive to alleviate or control some of the withdrawal symptoms. All of the addicts were men and used the drugs intravenously. All but one who used morphine were addicted to heroin, and some also, used cocaine. The 20 patients were divided in two groups: a group of 12 being given mephenesin as an adjunctive, and a group of 8 serving as controls and receiving no mephenesin. Methadone in decreasing amounts was substituted for the addictive drug in both groups. The initial dose of methadone varied from 10 to 30 mg. every four hours and depended upon the duration of addiction, amount of drug used, emotional stability, age, weight, and general physical condition of the patient. The optimal dose of mephenesin appeared to be 1 gm. every three hours. It was found that in patients receiving the adjunctive therapy withdrawal can be more rapid; muscle twitchings, cramps, and tremor can be controlled; and there is less anxiety. Patients are able to carry on a more normal existence, taking part in group activities and performing light physical duties; insomnia appears to be decreased. To be effective, however, the adjunctive treatment must be given early, before withdrawal symptoms appear.

*Barbers' Disease. W. Waris.—p. 111.

Barbers' Disease.—Waris presents the histories of three barbers in whom a sinus developed in the web between two fingers. He lists data on these cases and eight others that had previously been described in the literature. Most of these sinuses, which in previous reports were usually referred to as "pilonidal" sinuses because they contained hair, were on the right hand. They were more commonly in the web between the third and fourth fingers and less often between the second and third or fourth and fifth fingers. Hair clippings sometimes penetrate into the skin of the finger webs of barbers and cause a foreign body granuloma and cyst formation. A sinus of this kind containing short hairs may be quite harmless for many years before a secondary infection causes suppuration and surgical treatment is needed. These finger web sinuses are an occupational disease of barbers, but they are rather rare. It seems possible that the movements of the barber's fingers rub hair clippings into the finger web in such a way that the hair bores into the skin. Furthermore, the constant opening and shutting of the web may produce a negative pressure that promotes penetration of hair into the skin.

Specific Dynamic Action of Protein in the Aged.—Since widely differing specific dynamic action values in different subjects have been reported, it was thought that the differences might be related to the ages of the subjects. The experiments reported here were done to elucidate any possible role that age may play in the specific dynamic action of protein. The responses of old men (mean age 77 years) and young men (mean age 24 years) to the ingestion of a standard protein test meal, which yielded 25 gm. of protein, were compared. The specific dynamic action, expressed as total excess oxygen utilization, was essentially the same in both age groups. The older subjects exhibited a slower initial response to the protein meal but had both higher peak values and increased excess oxygen utilization during the second half of a 4.5 hours test period.

Modification of the Effects of Corticotropin by Potassium.—It is evident that the potassium-depleting, sodium-retaining, diabetogenic, and catabolic effects of corticotropin are undesirable effects clinically. Studies were undertaken in an effort to determine to what extent the biological activity of corticotropin in man might be modified by the simultaneous administration of large amounts of potassium salts. Five of the seven patients studied had active generalized rheumatoid arthritis, one had disseminated lupus erythematosus, and one had hyperinsulinism. Short-term and long-term studies were carried out. The patients received corticotropin in doses up to 100 units daily and, both separately and in combination, large amounts of potassium salts by mouth (up to 360 mEq. per day of potassium acetate). In most instances six day balance periods were employed. No untoward symptoms occurred, except for occasional nausea. A patient to whom corticotropin had been given for three months and in whom hypokalemia developed did not retain extra potassium when he was given 120 mEq. per day of supplemental potassium while corticotropin therapy was continued. These large doses of potassium salts administered concurrently with corticotropin did not modify the antirheumatic effects of corticotropin. Other effects of corticotropin that were not prevented included uric acid diuresis, eosinopenia, a rise in urinary nitrogen levels, a rise in fasting blood sugar levels, and a rise in 17-ketosteroid excretion. On the other hand, the effects of corticotropin upon electrolyte metabolism were definitely modified. The sodium retention that occurs when corticotropin therapy is initiated was prevented or diminished by the concurrent administration of adequate amounts of potassium salts. Starting the administration of potassium salts after corticotropin therapy was underway induced prompt diuresis of sodium. The sodium diuresis that ordinarily follows withdrawal of corticotropin therapy may not occur in patients who are receiving potassium salts concurrently. A transient (one to two days) positive phosphorus balance was produced by the administration of large doses of potassium salts.

Oral Administration of High Caloric Fat Emulsion for Total Feeding.—This study was undertaken to ascertain whether a high calorie, high fat liquid feeding could be administered as the sole source of feeding, and if this would be accompanied by gain in weight, restoration of positive nitrogen balance, and minimal alteration in normal metabolism. Six patients with fracture of the mandible and wiring received a high calorie liquid feeding, consisting primarily of a 40% emulsion of peanut oil, to which was added a protein concentrate and vitamins and minerals. In the preparation 100 gm. of protein concentrate, which also contained vitamins and minerals, was added to 1,000 ml. of the fat emulsion; 100 mg. of ascorbic acid, 4.0 gm. of sodium chloride as an isotonic solution, and 85 mg. of iron as ferric ammonium citrate were added. The preparation was mixed in a blender and refrigerated until consumed. Five of the patients consumed the arbitrarily determined amount of 1,000 ml. of the fat emulsion and supplements daily in divided feedings, which provided 4,370 calories. The sixth patient varied his daily intake over the period of study, beginning with a smaller amount of the preparation. The five patients gained weight while receiving the fixed amount of 1,000 ml. of fat emulsion. The weight gain ranged from 2.75 to 12.25 lb. (1,247 to 5,528 gm.) in from 12 to 24 days. The average daily weight gain was 0.4 pounds (181 gm.). Fecal fat excretion increased 7.68 gm. above the control level. No consistent changes occurred in fasting blood levels of total or neutral fat, phospholipid, cholesterol, serum total protein or albumin/globulin ratio, nonprotein nitrogen, fasting blood sugar, or carbon dioxide content.

Influence of Antihistaminic Agents on Erythrocyte Agglutination.—Reduction in the incidence of unfavorable transfusion reactions, which is important to leukemic patients and others requiring frequent and multiple transfusions, may be secured by adding certain antihistaminic agents to whole blood before its infusion. A significant retardation of the specific agglutination in vitro of group A and group B erythrocytes was noted when diphenhydramine (Benadryl) was added to anti-A and anti-B serums, and this led to further study of the inhibiting effect of diphenhydramine and other antihistaminic agents on isoagglutination of human blood cells in vitro. Tests of eight agents showed that diphenhydramine and pyrilamine maleate apparently had the greatest inhibitory effect on isoagglutination.

Methapyrilene (Histadyl) and tripelennamine (Pyribenzamine) exerted a slight inhibitory action, and cyclopentamine (Clopane) hydrochloride, antazoline (Antistine), a mixture of phenylephrine (Neo-Synephrine) and Thenfadil (*N*-[2-dimethylaminoethyl]-*N*-2-pyridyl-3-thenylamine), and dimenhydrinate (Dramamine) had essentially no effect. The use of diphenhydramine and tripelennamine in vivo appears to protect the recipient more effectively than can be accounted for by the results obtained in vitro. The isoagglutination reaction is retarded and weakened when antihistaminic agents are used in vitro, but eventual clumping of the cells is not prevented; in vivo, however, the retardation is apparently sufficient to overcome minor clumping due to atypical antibodies, thus preventing the characteristic clinical responses that usually follow. Sensitized erythrocytes from an infant with erythroblastosis fetalis were used to test the effect of antihistaminic agents on the anti-human-globulin (Coombs') reaction. Agglutination appeared to be retarded by pyrilamine maleate, tripelennamine, and dimenhydrinate. Only slight retardation was observed with cyclopentamine hydrochloride and the mixture of phenylephrine and Thenfadil, and the effect of the other agents, methapyriline, antazoline, and diphenhydramine, could not be evaluated because they produced hemolysis of the sensitized erythrocytes.

Nitrogen Metabolism and Liver Histology During Aureomycin Treatment.—Three patients with alcoholic fatty cirrhosis and one with convalescent hepatitis receiving aureomycin therapy were studied in an effort to determine the effect of aureomycin on nitrogen metabolism, liver histology, and liver function tests. Urine nitrogen excretion was increased in all four patients while they were receiving aureomycin, and the nitrogen balance became negative in two, although their diet remained constant. Methionine deficiency has been suggested as the cause of aureomycin-induced nitrogen loss, but simultaneous administration of methionine had no effect on nitrogen excretion in these patients. Fatty infiltration of the liver was observed after two weeks of aureomycin therapy in one patient and was not reversed when methionine was administered concurrently for another two weeks. Biopsy of the liver 10 days after administration of aureomycin was stopped showed almost complete disappearance of the fatty changes. Liver histology was improved or unchanged in the other three patients, in whom aureomycin therapy was limited to brief periods (five to seven days). Individual variations in the susceptibility of patients to fatty infiltration may account for the varying findings reported in this and other studies. No serious hepatic deterioration under aureomycin therapy was shown by any of the functional tests employed, but its prolonged use in conditions in which protein anabolism is therapeutically desirable would probably be injudicious.

Late Results of Thoracoplasty for Pulmonary Tuberculosis.—Thoracoplasty was done for pulmonary tuberculosis in 90 patients between 1935 and 1940 who were followed for 11 to 16 years. Six died postoperatively and four within the first year after the intervention. In the 80 patients living in 1941, the disease had been arrested in 64 and not arrested in 16. In 57 of the 64 patients the disease has remained inactive up to the present time. One patient with negative sputum committed suicide two years after the operation. Two patients who had inactive disease for long periods died of nontuberculous causes. Four patients had reactivation of their tuberculosis, but the disease has again become inactive in one. Of the 16 patients who still had positive sputums at the time of the first report, 6 had late sputum conversion, and subsequently the disease has remained inactive. One patient is clinically well, with occasional positive cultures, and is classified as having arrested disease. Active tuberculosis persisted in nine patients; eight of these died from 4 to 10 years after the operation and one is still alive. Thus 66 of the 80 patients alive in 1941 are still alive, 63 with inactive disease, one with arrested disease, and two with active tuberculosis. Four of the 14 who died had inactive disease at the time of death. Today, with the addition of the antibiotics, thoracoplasty performed on a selected group of patients should yield a very high percentage of early good results that can be expected to be maintained over a long period.

Repair of Wounds of Intrathoracic Trachea.—A 20-year-old private in the marine corps of the republic of Korea was struck by a bullet that entered his body in the left supraclavicular region and emerged through the right eighth intercostal space posteriorly. The patient had a right tension pneumothorax with pronounced mediastinal shift to the left. Endotracheal intubation was carried out and a posterolateral thoracotomy was performed through the eighth interspace. The left lung was almost completely collapsed, and it was soon apparent that a large defect was present in the trachea just proximal to the coryna. On careful dissection of this area two perforations were noted: an anterior longitudinal defect 2 cm. in length just proximal to the coryna, and another of the same size and type, just proximal to the anterior defect, on the esophageal aspect of the trachea. Despite these defects sufficient pulmonary aeration had prevailed to sustain life 24 hours. The vagus nerve was carefully dissected away, and the anterior tracheal defect was closed with interrupted silk sutures. The posterior defect was difficult to approach for suturing. A full thickness skin graft, large enough to encircle the posterior defect as well as to allow for retraction, was obtained from the patient's anterior abdominal wall. The graft was everted and passed around the trachea with the skin surface applied to the tracheal defect and the subcutaneous tissue in contact with the esophagus and other mediastinal structures. The graft was then sutured anteriorly with interrupted silk sutures to form a cuff around the tracheal defect, then sutured to the trachea superiorly and inferiorly on the anterior surface. Following this procedure, the lung could be expanded with positive pressure and without evidence of seepage of air or fluid through the defects or around the skin graft. A large catheter was inserted through a stab wound in the ninth interspace. The incision was then closed in layers. Bronchoscopy was performed following the operative procedure. The trachea was patent and dry. The thoracotomy tube was removed on the fourth postoperative day. Closure of the donor area on the anterior abdominal wall was performed on the 26th postoperative day by mobilization of superior and inferior skin flaps. A tracheogram performed on the 28th postoperative day showed an adequate tracheal lumen with a small area of indentation where the skin graft had been applied. The patient is well two months following operation.

Tracheal Resection and Replacement with Prosthesis.—Experiments to determine whether or not it would be possible to make a complete segmental resection of a portion of the trachea and replace this segment with a prosthesis were carried out on dogs. Results showed that the trachea can be resected in the neck or thorax of the animals and that the trachea will regain its continuity over a prosthesis. The prosthetic tube used was constructed of layers of fused polyethylene in which wire was incorporated to prevent cutting through of the sutures with motion. This permitted adequate fixation until continuity was reestablished, and in some instances the anastomosis could be instituted and maintained as an airtight channel. While a segmental tissue defect will regenerate with fibrous tissue, however, this tissue is not capable of supporting itself and stenosis will result when the prosthesis is removed. True tracheal regeneration did not occur. This would indicate that a prosthesis to replace the entire circumference of a resected segment will not be practical to use on human patients. In addition, a prosthesis offers a mechanical barrier to the evacuation of bronchial secretions. Because the prosthesis can be sutured without the sutures cutting out, this type of prosthesis might find other use as replacement for damaged or destroyed blood vessels or possibly resected esophageal segments. In a 63-year-old patient with squamous cell carcinoma of the trachea, the anterior half of the trachea containing the tumor was resected and a polyethylene tube prosthesis was placed to occupy the defect. The incision was closed after fixation of the prosthesis in place with interrupted sutures around the perimeter of the tracheal defect. On the second postoperative day partial atelectasis of the right lung developed that resulted in death the next day. Necropsy revealed an enlarged right heart, mediastinitis, and partial atelectasis of the right lung.

Subdural Effusions in Infancy.—Clinicians are now compelled to give their attention to new complications and new sequelae of previously lethal diseases. Subdural effusion in childhood is one of these. This condition usually begins with meningitis in an infant aged 1 year or less. With appropriate antibiotic therapy a "cure" is effected, but the infant remains or becomes listless, pale, anorexic, and irritable. The meningitic process is often blamed, and the conclusion is drawn that irreparable brain damage has resulted from the acute illness and accounts for the whole process. Convulsions, focal paralysis, and stupor may also occur. Stevens and Williams feel that their observations on 30 cases of nontraumatic subdural effusion suggest that this is a common lesion, which can be diagnosed, and that corrective measures may be necessary to prevent neurological complications and to salvage the child's mentality. If the diagnosis is suspected, bilateral subdural taps should be made at the extreme lateral margin of the anterior fontanel or through the coronal suture about midway between the extreme corner of the fontanel and the zygoma. If more than 2 cc. of fluid is found, subdural effusion may be said to be present. The volume obtained with each subdural drainage varies, and in some cases the subdural space eventually "dries up." Whether the subdural effusion can be completely eliminated and all symptoms resolved without sequelae by repeated subdural taps can be determined only by further studies. It is the impression of these authors that, even if the effusion is "dried up" by repeated drainage, a vascularized thickened neomembrane may still remain to encapsulate the brain and strangle its growth. The authors present case histories. These subdural effusions usually occur in infants less than 1½ years old following meningitis, which is usually due to Hemophilus influenzae or Diplococcus pneumoniae. No single diagnostic criterion is reliable, but the history of any meningitis should arouse suspicion, particularly if the child's physical and mental development is not progressing. Subdural taps are essential in such a condition and are considered safe and simple. If subdural fluid persists, it may be inferred that a constricting membrane has formed, necessitating surgical removal in most instances. Morbidity from this membrane may be grave. In addition to meningitis as a cause of subdural effusion, the clinician should be alert to the possibility of such effusion occurring in cachectic children, for example, in children with chronic severe diarrhea. The treatment is the same.

Bodily State in Injuries of Spinal Cord.—The nervous regulation of various bodily functions requires that the influences from centers in the cerebral cortex, diencephalon, and brain stem be transmitted through the autonomic nervous system. Many of these influences reach the viscera or tissues to be regulated through the spinal cord. In injuries of the spinal cord, most attention has been given to the disturbances in motion, sensation, reflexes, bowel and bladder function and the nutritional state, particularly bed sores. Alterations in other bodily functions, such as cardiovascular regulation, glucose metabolism, water metabolism, temperature regulation, and gastrointestinal activity, have been given little attention. Chor and his associates found the basal blood pressure to be low in cervical cord lesions. Orthostatic hypotension occurred oftenest in cervical cord lesions, and momentary loss of consciousness often resulted when the erect position was attempted. A reverse reflex hypertension, with headache and other unpleasant sensations, occurred during the administration of enemas. Glucose tolerance curves were abnormal, although there was no evidence of disease of the liver, pancreas, adrenal glands, and thyroid. There was a defect in concentration of the urine as well as in the day-night ratio, in the absence of signs of kidney disease. There was stasis in the colon as determined by charcoal excretion tests. Gallbladder evacuation and concentration were normal. Diarrhea was observed occasionally. A constant finding in cord injuries was a great loss of weight, which usually was not regained. Hunger and thirst were experienced as well as a sensation of fullness after eating. Nausea was produced by various stimuli as well as by retained feces and calculi. Hiccoughs were due to the usual causes. The water intake was greatly increased, particularly in cervical cord lesions. Death in patients with spinal cord lesions has usually been attributed to infection, especially of the urinary tract and terminally of the lungs. In analyzing the clinical histories of those who died the authors found that in most cases genitourinary infections were not the only cause. Many of them had had recurrent attacks of sepsis. Most of them had had several surgical procedures performed. Severe decubitus, osteomyelitis, heart lesions, pulmonary disease, gastrointestinal complications, and general nutritional disturbances were encountered. Even when the terminal picture was that of uremia due to kidney failure, other factors contributed to the fatal outcome in many cases.

Betaine and Guanidineacetic Acid in Treatment of Poliomyelitis.—The purported value of betaine and guanidineacetic acid (glycocyamine) was investigated in nine patients who had residual muscle weakness following an attack of poliomyelitis one or more years previously. All of them were cooperative adults who had reached a stage at which increases in muscle function were absent or minimal. A 10th patient was studied who had had infectious polyneuritis several years previously, with residual paralysis of the muscles of both legs. To make the evaluation as objective as possible, the strength of the muscles studied was measured by means of a special instrument known as a Myodynemeter, utilizing a strain gage with a calibrated recording device and standardized test positions. A total of 76 muscle actions were recorded, since 2 to 13 different muscles were tested in each of the 10 patients. Tests of the following muscle actions were included: wrist flexion and extension; elbow flexion and extension; shoulder internal rotation, vertical and horizontal abduction, and extension and flexion; foot dorsiflexion, eversion, inversion and combined dorsiflexion and inversion, and knee extension and flexion; and hip flexion, extension, adduction, abduction, internal rotation, and external rotation. The patients were given guanidineacetic acid in daily doses of from 3 to 5.5 gm. and betaine in doses of 20 or 25 gm. daily. The patients were told that this was an experimental study to determine the benefits of new drugs. Efforts were made not to show any enthusiasm for the drugs. Only 26% of the muscles tested showed as much as a 20% increase in strength, which did not appear significant subjectively or functionally. When increases in strength occurred, they appeared in muscles that had not received intensive exercise to increase power. Under the conditions of this study, betaine and guanidineacetic acid were not considered to have significant value in the treatment of muscle weakness resulting from poliomyelitis.

Plantar Warts: Cure by Injection.—The simple treatment here described was accidentally discovered by a surgical technician, who, having been approached by a soldier with a plantar wart and a desire to march in a special parade, injected the wart with procaine (Novocain) as a temporary expedient. The soldier marched in the parade, and in a few days the plantar wart disappeared. After this the method was successfully applied in 48 patients. It has been possible to follow 30 of these for six months and 22 of them were cured. In seven cases a plantar wart was still present but was asymptomatic. Only one patient showed no improvement after three injections. Three patients in the series had extensive plantar warts of the mosaic type and were cured. One of these had approximately 30 warts involving the entire plantar surface of the left foot, and treatment by any of the currently accepted methods would have been extremely difficult. The treatment consists of the injection of 2 or 3 cc. of 1% procaine under pressure into the base of the wart in the stratum germinativum layer of the epidermis. Best results are obtained with the use of a 26-gage needle and a Luer-Lok dental syringe. The needle should penetrate to the stratum germinativum through normal skin at the side of the wart; and only one needle puncture should be made, because the injected fluid escapes through multiple holes and sufficient pressure cannot be obtained. If the needle is properly placed, there is considerable resistance to injection, and the desired marked blanching of the skin and elevation of the wart will result. Patients usually become symptom-free within 24 hours. In five to seven days the wart becomes soft and darkened. Usually, it can be lifted out with a thumb forceps after a week.

Pseudoprecocious Puberty as Result of Estrogen Ingestion.—The first of the two patients with pseudoprecocious puberty who are described here was a girl, 4 years and 3 months old. She was referred to the hospital because of tenderness and enlargement of both breasts, with dark pigmentation of the areolae, of three weeks' duration. Two days before admission scanty vaginal bleeding had occurred. A preoperative diagnosis of a solid tumor of the left ovary (with a question of granulosa cell tumor) was made, and an exploratory laparotomy performed. The uterus and fallopian tubes proved to be enlarged and hyperemic, but no abnormal masses were found. Histological studies of biopsy material showed normal preadolescent ovarian tissue, with no evidence of follicular activity. After the laparotomy further questioning revealed that diethylstilbestrol had been in the house and easily available to the child, the mother having taken the drug until four months before the appearance of the child's precocious breast development. Follow-up examination one month postoperatively showed complete regression of the breast enlargement and a considerable decrease in the pigmentation. No further vaginal bleeding had occurred. The second case occurred in a 7-year-old girl, who was referred to a Children's Medical Center because of bilateral breast enlargement of four weeks' duration and vaginal bleeding that had begun three days before admission. Further investigation revealed that the child, who attended a boarding school, was taking four pills three times a day that supposedly were vitamin preparations. Bioassay of the suspicious tablets in female rats revealed the presence of estrogenic activity. Further inquiry established the fact that the patient's father had mistakenly given her diethylstilbestrol instead of ascorbic acid tablets. Examination two months later showed that the signs of precocious puberty had disappeared. The authors suggest that areolar pigmentation in young girls might suggest the possibility of diethylstilbestrol ingestion. They advocate postponing laparotomy for two to four weeks when the pelvic findings are negative or equivocal.

Postoperative Stricture of Biliary Tract.—Pierce and Marnane describe four cases of loss of continuity of the common bile duct after cholecystectomy, at least three of which are attributable to surgical bile duct injury. In the fourth case an inflammatory process seemed largely responsible. A surgeon's prompt realization in one of the cases of the probable cause of the difficulty, which developed a few days after a presumably uncomplicated operation, and his immediate referral of the case to a surgeon with greater experience in the treatment of such injuries proved to be very important. It is now six years since the last common duct injury occurred in the hospital with which the authors are connected. At that time the surgical staff discussed gallbladder disease and stressed that even in the "easy" cases caution is required. There is a high incidence of congenital anomalies of the biliary system. The surgeon should familiarize himself early in the operation with the exact location of the structures of the gastrohepatic ligament, so that bleeding from the cystic artery may be controlled by pressure of the hepatic artery between the thumb and forefinger, obviating the hasty, blind application of clamps. The angle between the cystic duct and the common duct should be well exposed. The cystic artery should be exposed to its entrance to the gallbladder and tied close to this point. It is safer to tie the cystic duct before clamping, and the clamp should be distal to the well-visualized tie. One should beware of applying ties or clamps while traction is applied to the gallbladder. The duct system with lax peritoneal investments is easily knuckled. In acute cases, if the landmarks are obliterated by edema, a cholecystostomy may be the operation of choice. Secondary removal of the gallbladder is a far less formidable procedure than repair of the injured ductal system. At the end of a cholecystectomy, the bile ducts should be carefully inspected; if the surgeon finds that injury has occurred, he should repair it immediately. Any surgeon who undertakes a gallbladder operation should be ready to carry out this procedure. If it becomes apparent early in the postoperative period that injury has occurred, a surgeon experienced in plastic repair on the biliary tract should be consulted at once, so that repair will not be further complicated by increased scar tissue of unsuccessful secondary operations.

Vitamin A Intoxication in an Adult.—A 52-year-old woman was seen in consultation by the author because her physician wanted to ascertain the cause of spontaneous bleeding from the mucous membranes. She had had generalized flaking of the skin since childhood, and about 4½ years previously cracking and oozing about the skin of the legs had developed. When various treatments did not give relief, her physician started vitamin A therapy. In the early part of 1948 she received 150,000 I. U. of vitamin A and 100 mg. of an antihistamine daily for the first week and 100,000 units of vitamin A daily thereafter. The latter dose of vitamin A was taken from the early part of 1948 until Feb. 29, 1952. Insomnia and listlessness began in the early part of 1949. Another year elapsed before she began to note loss of scalp hair. Extraction of the upper teeth exemplified the danger of hemorrhage from the gums and mucous membranes and its correction by administration of vitamin K. The relation of pulsating exophthalmos to vitamin A intoxication, if any, is unknown. The patient never complained of a pulsating headache until a month before vitamin A therapy was stopped; the headaches still persist. The fact that she was completely relieved of her joint pains and aching bones, with regrowth of lost hair within six months of discontinuation of ingestion of vitamin A, is interpreted as evidence of toxicity to vitamin A ingested in large doses over a prolonged period. This case proves that vitamin A intoxication is not limited to infants and children. Sulzberger and Lazar recently described this syndrome in an adult who was inspired to self medication with large doses of vitamin A by a radio "nutrition commentator." In its major clinical manifestations the syndrome appears to be the same whether it occurs in children or adults. This case again emphasizes and confirms the opinion of previous authors that "physicians administering large doses of vitamin A must be on the lookout for signs and symptoms of toxicity."

Pancreatic Function Tests.—In reviewing the more important laboratory method of studying external pancreatic function Dreiling considered (1) the examination of blood enzymes, (2) examination of feces, and (3) examination of duodenal drainage. The results of studies on patients with normal and abnormal pancreatic function are presented in tables, and the author arrives at the following conclusions: 1. Blood amylase elevations, when present, are of diagnostic significance, but no correlations can be made on a quantitative basis. The results of the various so-called provocative blood enzyme tests are indeterminate. 2. Chemical analysis of the stool furnishes information as to the completeness of digestion and absorption but cannot be used as a reliable quantitative index of pancreatic function. The secretin test yields quantitative data concerning the external pancreatic secretion. Its value in the diagnosis of acute pancreatitis is limited by the rapidity with which the external secretion returns to normal ranges. Pancreatic cancers and chronic pancreatitis can be diagnosed by the characteristic alterations produced in the secretin test responses. In the advanced stages of both diseases, the secretin responses are no longer diagnostically distinct. To overcome this drawback, some investigators combined the secretin stimulus with insulin, methacholine (Mecholyl), or bethanechol (Urecholine). These agents, although potent enzyme stimuli, have the disadvantage of producing not only cardiovascular side-reactions and disturbing changes in gastrointestinal motility but also of stimulating the production of large amounts of gastric acid. The author feels that a standardized preparation of a pancreatic enzyme is needed to complete the secretin test.

*Toxaphene Poisoning—Report of Fatal Case. R. W. Pollock.—p. 293.
Changing Panorama of Medical Care and Some of Its Implications in Medical Education. E. L. Turner.—p. 295.

Fatal Case of Toxaphene Poisoning.—Toxaphene is widely used as a pesticide against agricultural insects. It is used as a dust, emulsion, spray, wettable powder, and bait. When ingested, toxaphene acts on the central nervous system and causes generalized convulsions of a tetanoid or clonic nature. The selective activity of toxaphene on the central nervous system is best explained by its high lipoidal solubility. All species of animals used in testing this pesticide manifested generalized convulsions. Sublethal doses caused shorter and fewer convulsions. If the dose was lethal, death was due to respiratory failure after a series of convulsions of increasing severity. Warning symptoms such as nausea, abdominal cramps, and vomiting are absent in toxaphene poisoning. Convulsion with loss of consciousness is the cardinal symptom. In the treatment gastric lavage with strong saline solution is used to clean the stomach and saline cathartics to clean the intestines. Dogs survive ingestion of large doses of toxaphene when it is administered in an indigestible oil. Mineral oil, when given early, is effective in decreasing absorption and therefore should be given by prompt gavage or by mouth. The drugs of choice in combating the convulsions in experimental animals are the barbiturates. The authors report a fatal case in a girl, aged 16 months, who was found playing in the yard with a thick, molasses-like substance on her face and hands, the source being a discarded gallon can. After reading the directions on the label, the mother washed the child's face and hands and gave one-third of a glass of salty water. Fifteen minutes later the child was forced to drink one-half of a glass of salty water. The child did not vomit. One-half hour later the mother noticed that the child was limp and turning blue. The child was at once driven to the hospital, but convulsions started en route and never ceased until 10 minutes before death, three and one-half hours later.

*Spontaneous Rupture of Apparently Normal Uterus During Pregnancy: Review. L. B. Felmus, P. Pedowitz and S. Nassberg.—p. 155.
Possible Role of Smegma in Etiology of Squamous Cell Carcinoma of Cervix Uteri (With Short Review of Literature). R. Fischer.—p. 232.

Spontaneous Rupture of Uterus During Pregnancy.—This review is concerned only with spontaneous rupture of the uterus during pregnancy without apparent cause. In addition to 116 cases found in a thorough search of the literature, 5 new cases are described, 3 observed by the authors of this paper and 2 from other hospitals. Although there may be no apparent cause for rupture of the gravid uterus, careful analysis of the patient's history may reveal a predisposing factor. Except for previous cesarean section and myomectomy, the most common predisposing factors for rupture of the uterus before the onset of labor are previous intra-uterine manipulation (such as curettage and manual removal of the placenta) and postabortive or postpartum sepsis. Intra-uterine infection during pregnancy also may be a cause of rupture. Thrombosis of a uterine blood vessel with infarction of the myometrium is reported for the first time as a cause for rupture before labor. Among the less common causes are adenomyosis uteri with excessive trophoblastic penetration of the myometrium, the thinned uterine wall of the multipara, congenital abnormalities of the uterus, and cornual or angular pregnancies. Spontaneous rupture of the uterus during pregnancy is most frequent during the last trimester but may occur as early as the fourth month. Rupture before the sixth month of gestation occurred in 35 cases and after the sixth month in 71 cases. The time of rupture in the remaining 15 cases was not recorded. In contrast to the characteristically lower uterine segment rupture during labor, the laceration during pregnancy is almost always in the corpus of the uterus. Rupture, however, may occur in the lower segment when infarction involves that area. The symptoms and signs of spontaneous rupture of a gravid uterus may vary from vague, mild abdominal pain to those of an acute abdominal catastrophe with general collapse. When the rupture is complete, fetal parts may be palpated directly beneath the abdominal wall. The accompanying abdominal distention, nausea and vomiting, and evidences of peritoneal irritation indicate the presence of an acute surgical emergency. In most cases, however, the fetus is not extruded into the abdominal cavity. Abdominal palpation usually reveals only a tender uterus, similar to moderate premature separation of the placenta. A deceptively slow decline in the level of hemoglobin confuses the diagnosis, so that laparotomy is often deferred, a delay that may prove fatal. When there is doubt, exploratory laparotomy should be done. The maternal death rate increases in direct relationship to the time elapsed between rupture of the uterus and laparotomy for the arrest of hemorrhage. Shock is not a contraindication to surgical treatment in these patients. Adequate blood replacement may mean the difference between life and death, and intra-arterial transfusion may be necessary.

Anaphylactic Shock Following Administration of Penicillin.—Untoward effects of penicillin are not the result of direct toxicity but of hypersensitivity. They mainly consist of urticaria, contact dermatitis, gastrointestinal reactions, arthralgia, and drug fever. Because of the antigen-antibody mechanism of penicillin reaction, as has been experimentally demonstrated, one has to be aware of a more serious reaction based on the same mechanism and known as anaphylactic shock. Nikishin found only five instances of true anaphylactic reactions to penicillin in the available literature. In reviewing the characteristics of these patients, the author says that all but one had received penicillin several weeks prior to the injection that was followed by shock, but none manifested signs of sensitivity during previous administrations. The patients received the "exciting doses" intramuscularly; intravenous injection could be proved in none of the patients. The reaction began almost immediately. It was manifested by flushing of the face, choking, wheezing, dyspnea, and a subjective feeling of tightness in the chest and throat, followed by extreme circulatory depression with a rapid, weak, almost imperceptible pulse, low or unobtainable blood pressure, profuse perspiration, and collapse. Antiallergic treatment was successful when it was employed. The author also reviews two previously reported fatal cases of anaphylactic shock following injection of penicillin and then describes a case of his own observation, in which recovery followed various treatments. The use of drugs with antihistaminic effects proved effective in this as well as in other cases. Avoiding the allergen prevents anaphylactic shock, but an occasional inadvertent intravenous injection is apparently unavoidable. The mishap will be less frequent if the use of small caliber needles for intramuscular injections is discontinued. It seems impracticable to test the sensitivity of every patient in need of penicillin, but the author pleads for discrimination in the use of penicillin as well as other antibiotics. The duration of drug allergy is unpredictable, but may last many years and may become evident in a fatal anaphylactic shock. The number of penicillin sensitive persons is probably increasing with widening use of this powerful drug.

Febrile Convulsions.—Convulsive seizures that attend a febrile illness are significant because of the number of children involved. Figures from various reports and a gross estimate suggest that about 2% of all children have one or more febrile seizures in the first five years of life. Although many pediatricians believe that a fever seizure is an innocent symptom, the counterpart of a chill in an adult, Lennox feels that a febrile seizure cannot be easily dismissed. He suggests that a convulsive seizure in association with fever may mean one of six things: 1. The fever may be a consequence of a spontaneous seizure, the result of an excess of muscular energy and heat. 2. The seizure may be the result of excess hydration or of antibiotics given to combat an infection. 3. The fever may be a seizure phenomenon, the result of a paroxysmal seizure discharge in the region of the hypothalamus. 4. The seizure may be due not to the fever but to bacterial toxins. 5. It may be the secondary result of an invasion of the brain by the infectious organisms. 6. The seizure may be due to none of these, but may be the response to high fever in association with some infection. In addition, the seizure may not be the consequence of fever, but both fever and seizure may be a consequence of toxic action on brain cells. The following features have not yet been satisfactorily explained: 1. Fever-induced seizures occur mostly in the very young. 2. Almost invariably the febrile seizure is the child's initial seizure. 3. Response to fever is almost invariably a convulsion rather than some other manifestation of epilepsy. In a study of persons whose first convulsive seizure occurred during the first decade of life it was found that extreme youth and absence of pathologic changes were oftenest associated with febrile seizures. Among a total of 407 epileptics who suffered fever convulsions as the first manifestation, 76.9% subsequently experienced nonfebrile seizures. In 22% an interval of five years or longer separated the last febrile seizure from the first nonfebrile one. The fact that subsequent seizures were mostly psychomotor seizures suggests that febrile seizures may sometimes be accompanied by temporal lobe lesions. Febrile seizures are usually innocuous, but if prolonged, focal, or attended by much cyanosis or protracted coma, they may cause brain damage. Of 392 patients who sustained brain injury in the first 10 years of life, febrile seizures were blamed for the injury and the continuing epilepsy in 5.4%. The genetic influence in children having fever-induced seizures is very strong. In the author's group, this influence, as measured by the incidence of epilepsy among near relatives, is approximately double the genetic influence in young children having only nonfebrile seizures. If evidence of hereditary transmission is accepted as indicative of essential epilepsy, then a febrile seizure is epilepsy. Fever-activated epilepsy is short lived, however; the majority of children with this form had only one or two seizures.

Carcinoma Involving the Esophagus.—Although surgical procedures for removal of segments of the esophagus have been carried out in an increasing number of centers, with decreasing immediate mortality, few objective reports of over-all and end results are available. At the Presbyterian Hospital in New York City 228 patients with carcinoma involving the esophagus were treated in the 10 year period from 1941 through 1950. Of these, 162 had primary carcinomas of the esophagus; 47 had carcinomas of the stomach with extension to the lower esophagus; and 19 had carcinoma involving the esophagus but originating in some other structure. Most of the patients were in the sixth and seventh decades of life, and the ratio of men to women was approximately 4:1. One patient is living and apparently free of disease seven years after resection of an adenocarcinoma of the cardia involving the esophagus. No patient has survived five years after resection of a primary carcinoma of the esophagus. No patient lived more than one year after involvement of the esophagus in carcinoma originating in another structure other than the stomach. Improvements in operative techniques have resulted in substantial decrease in operative mortality during the second half of the period studied and may result in a higher proportion of long-term survivors, especially if greater selectivity is exercised in resorting to resection. Whether resection for palliation in cases with demonstrable irremovable metastases is justifiable as compared to results of radiotherapy remains in doubt. The authors feel that in order to achieve reliable evaluation of the therapeutic methods of this highly fatal disease, the results in unselected series rather than in series selected for operability should be reported.

Circulating Eosinophil Cells and Specific Desensitization in Hay Fever Patients.—Eosinophil counts just before and one hour after exposure to Timothy pollen demonstrated varying reactions in hay fever patients, depending on whether or not the patients had previously received specific treatment. Eleven patients who had not previously been treated and two persons allergic to fungi reacted to exposure to the specific antigen by an average increase of 46% in the eosinophil count, while 13 previously treated hay fever patients had an average decrease of 51% in the number of eosinophils. These results show that untreated and treated hay fever patients have distinctly different reactions to specific antigens in which the adrenals seem to play an important part. For the present no conclusions may be drawn as to the way in which the organism is affected by specific desensitization.

Effect on Blood and Bone Marrow of Corticotropin and Cortisone.—Studies were made on the blood and bone marrow of three patients with arthritis who had been treated with corticotropin and cortisone. There was evidence of stimulation of the erythropoiesis and myelopoiesis, with transient reticulocytosis and an increase of the mature segmented cells. The previously inhibited maturation of the bone marrow tended to become more normal. The lymphocytes were not noticeably influenced. Continued administration of corticotropin elicited normal stimulation of the adrenal cortex, as reflected in marked eosinopenia; a slight decrease in eosinopenia was noted after treatment with cortisone. The serum iron level temporarily increased in some patients. The hyperplasia of the reticular cells of the bone marrow seemed to decrease simultaneously with a change in the phagocytosis. The lack of uniformity in the changes observed may be due to the varying dosage. The changes were less marked with cortisone, probably because cortisone affects the metabolism less than corticotropin does.

*ACTH Treatment in Case of Cyanide Poisoning. I. Lurie.—p. 87.

Corticotropin in Cyanide Poisoning.—The occurrence of cyanide poisoning is reported in a healthy 47-year-old man who entered by mistake a room that had not been ventilated after fumigation with hydrocyanic acid gas. The patient was given methylene blue, nitrites, and calcium thiosulfate, but did not respond. He lost consciousness and sank into deep coma. His condition improved rapidly after intravenous infusion of 25 mg. of corticotropin (ACTH). The dose was repeated after 3 hours and the patient regained consciousness after 12 hours. No explanation can be offered for the role played by corticotropin in cases of poisoning. The author believes that in the case reported the addition of corticotropin to the usual therapy played a decisive part; the prompt improvement in the patient's condition immediately after the administration of corticotropin was very impressive. There should be no hesitation in giving corticotropin a therapeutic trial in cases of severe cyanide poisoning.

Symptomatology of Myoclonias. E. Krebs.—p. 268.
*Diffuse and Multiple Sclerosis. G. de Morsier and H. Feldman.—p. 279.

Diffuse and Multiple Sclerosis.—Diffuse sclerosis cannot be distinguished from the classic form of multiple sclerosis by any exact criteria, and differential diagnosis is complicated by the frequent occurrence of transitional forms. The terms diffuse sclerosis and Schilder-Foix disease are generally applied to a progressive condition found chiefly in children and young adults that is characterized by varied neurological manifestations, principally psychic disturbances, ocular signs, and those of pyramidal origin. The most striking characteristic is a primary, progressive, sclerosing process affecting the two hemispheres, either unequally or symmetrically, sparing the cortex and to a variable extent the subcortical arcuate fibers (Meynert's U-shaped fibers). The only constant abnormality in all the diseases in this group is diffuse bilateral demyelination of the oval center. Diffuse sclerosis usually progresses rapidly and remissions are rare. An unusually prolonged case of 29 years' duration was presented by a woman who was treated for pulmonary tuberculosis between the ages of 12 and 20. Lesions of the apex of the left lung necessitated a pneumothorax, after which her pulmonary condition was satisfactory. Mental disturbances, irregularities of behavior, and manual awkwardness appeared at 20; at 30, there was decided muscular weakness in the left forearm and hand, and the shock of a broken engagement to be married intensified her complaints. Her walk became ataxospasmodic about 10 years later and her mental condition deteriorated still further; at the age of 50, she entered the hospital, scarcely able to walk. Her course was steadily downward and five months later she died. Autopsy showed foci of demyelination of the multiple sclerosis type. Other foci, however, resembled those found in diffuse sclerosis; demyelination was irregular and predominantly hemispheric, cells containing granulolipid bodies were present, and there was marked perivascular lymphocytic infiltration.

Tuberculosis in Bornholm After BCG Vaccination.—Changes are reported in the incidence of tuberculosis among the population of the Danish island of Bornholm in the Baltic sea under steadily increased BCG vaccination. Between 1936 and 1940 the first mass examinations were carried out of persons up to the age of 35 years. These studies revealed that persons with a negative tuberculin reaction were predisposed to infection. As the island population became more and more tuberculin-negative, it was decided in consultation with the Danish State Serum Institute, to begin propaganda in favor of increased BCG vaccination. Between 1941 and 1945 extensive vaccination was carried out in the schools. By the end of 1945 about 23% of the entire population had been vaccinated. Most of the vaccinated persons were between the ages of 7 to 20 years. As a result of this increased BCG vaccination the incidence of tuberculosis has decreased perceptibly. At the same time the number of persons whose reactions reverted from positive to negative increased, including persons with a natural positive reaction and those with a BCG-induced positive reaction; this situation necessitated an increasing number of revaccinations. BCG vaccination also changed the age distribution curves of newly reported cases of tuberculosis, so that the former peak at about the age of 20 has now been entirely leveled off. To make the BCG vaccination as widespread as possible, a second mass examination was carried out in 1946 and the entire population above school age were invited to attend. By the end of 1946 a total of 17,563 persons or 33.9% of the population had been vaccinated. Statistical data showed that the annual rate of infection per hundred per year of observation is only 2.5 and that the duration of BCG immunity ascertained by positive reactions to tuberculin drops slowly in the course of years, particularly during the first postvaccination years. New cases of tuberculosis and deaths from the disease are most frequent among persons with negative reactions and less frequent among those with positive reactions, but the incidence of new cases is lowest among those who had been vaccinated with BCG. Between 1946 and 1948 Bornholm fishermen had been catching salmon along the coast of Poland where they made contact with a highly tuberculous population. Two of these fishermen who had a negative reaction to tuberculin and had not been vaccinated were infected. On their return to Bornholm they passed the infection on to younger unvaccinated members of the family, with the result that nine cases of tuberculosis occurred in the course of two years. A similar tuberculous infection in Norwegian fishermen passed on in some Norwegian parishes where BCG vaccination had not been carried out spread widely, with hundreds of persons being infected in a short time. Tuberculosis in Bornholm is on the decline. Immunity in the population will be maintained by continuing with widespread BCG vaccination. Today Bornholm has 48,000 inhabitants and 49.6% of them had been vaccinated with BCG up to the end of 1950. Since 1949, examinations by age groups of 1, 7, 13 and 25-year-old persons have been done by the Bornholm tuberculosis dispensary. In addition all those taking up residence in the island are examined. Each examination consists of a tuberculin test followed by BCG vaccination of all those with a negative reaction, and x-ray screening of all school children and adults with a positive reaction. In addition, systematic examinations of adolescents attending schools, of men in the armed forces, seamen, and school teachers and the now compulsory examination of apprentices are continued. It is hoped that by this method the rate of the infection will be further reduced and at the same time the immunity among the population increased.

Osteopathia Patellae Juvenilis: Two Cases. H. Classen.—p. 543.

Pathogenesis of Sudeck's Syndrome.—The dystrophy of an extremity, first described by Sudeck in 1900, was later designated as Sudeck's syndrome. According to Hackethal various theories have been advanced to explain the pathogenesis of this syndrome, and the two most widely accepted at present are: the reflex theory of Vulpian-Charcot and the peripheral humoral theory of Rieder. The author feels that neither of these, nor various other theories are entirely satisfactory. On the basis of observations on 27 cases of Sudeck's syndrome of the upper extremity, the author regards the syndrome as the terminal stage of a neurodystrophic process. This neurodystrophic theory explains Sudeck's syndrome as the direct result of a serious dissociated irritation and paralysis of the nerve fibers of a certain area. The most common, but by no means the only cause is nerve strangulation, particularly strangulation of the nerve root. The hub of this process is the spondylogenic nerve root irritation, that is, mechanical root irritation produced by a disproportion between the size of the vertebral foramen and the nerve root diameter. The relative stenosis of the vertebral foramen is an important predisposing factor; and an ascending neuritis is probably the most important factor in the development of Sudeck's syndrome. The author considers causalgia as an especially severe form of Sudeck's syndrome, which is probably most often produced by massive nerve compression.

Value of Sodium Salicylate in Prevention of Heart Diseases in Rheumatic Fever. D. Barbato.—p. 73.
*Acute Porphyria: Case. C. A. Escande, C. Boccoleri, R. García Güelfi and L. E. Folle.—p. 83.

Acute Porphyria.—Acute porphyria in children is extremely rare. The authors report a case in a girl who was apparently normal until the age of 12, when she complained of lumbosacral pain and redness of the urine. A clinical diagnosis of acute porphyria was confirmed by the positive results of fluoroscopic and spectroscopic examination of the urine for porphyrins. The early symptoms were followed by abdominal pain and in two weeks by an ascending Landry's paralysis, which progressed to diaphragmatic paralysis. The latter was controlled by the use of the iron lung for 5 days on one occasion and for 35 days on a second occasion. After a stormy course, the symptoms regressed slowly. Cure with complete muscular recovery was obtained in a year. Porphyrinuria was revealed in the father and three out of five siblings of the patient by fluoroscopic examination. According to the authors, porphyria is a hereditary disorder of the metabolism of porphyrins that can be either latent in the form of porphyrinuria or else develop into the cutaneous or the acute forms of the disease. The cause of the metabolic disorder is unknown. The treatment is symptomatic. The authors advise physical and mental rest, an antiallergic diet, administration of 100 to 200 mg. of nicotinic acid amides by mouth daily, daily intramuscular injections of 5 cc. of raw liver extract, use of antibiotics if infections, especially respiratory infections, occur, and administration of calcium gluconate in daily doses of 1 or 2 gm. by intramuscular route. The authors do not specify the duration of the treatment. The use of the iron lung is indispensable in disorders of respiration of neurological origin. Sulfonamides and corticotropin (ACTH) aggravate this disease.

Crystalline Visammin in Coronary Insufficiency.—Of 500 men with coronary insufficiency, 50 who did not respond satisfactorily to treatment with nitrites and theophylline compounds were given crystalline visammin (khellin) orally in doses varying from 60 to 300 mg. daily. In 25 of these the insufficiency was characterized predominantly by symptoms of generalized vascular sclerosis; in 19 autonomic disturbances were manifested by the altered dermographic latent period, increased reflexes, and tendency to sweating, which indicated a definite deviation of the vegetative tonus to the vagotonic or sympatheticotonic side. The remaining six patients had cardiac decompensation due to angina pectoris. In the group with predominantly sclerotic symptoms, the optimal dose of the drug seemed to be about 120 mg. per day, which was adequate to render 11 patients free of complaints. The one definite therapeutic failure in this group was a patient with irritation of the pleura. Apparently the irritated pleura maintained the coronary disturbance through viscerovascular reflexes. Fifteen of the 19 patients with disturbance of the autonomic nervous system obtained good results, while 4 were therapeutic failures. In three of the latter pronounced hypotonic orthostatic disturbance was demonstrated by the electrocardiogram made in standing position and by Schellong's experiment. Kymographic recordings showed a pronounced contractile dysfunction of the heart in the fourth patient. Three of the six patients with cardiac decompensation responded satisfactorily to crystalline visammin. One patient with a combined aortic-mitral lesion had been refractory to treatment with Convallaria majalis for two weeks, and another with aortic valve insufficiency had not responded to previous treatment with a proprietary squill glycoside preparation for 17 days. The third patient with a left bundle branch block on a sclerotic basis responded to the small dose of 0.12 mg. of strophanthin combined with 200 mg. of crystalline visammin. The other three patients were therapeutic failures, probably because the dose was too small. The number of patients with cardiac decompensation due to angina pectoris is too small to draw conclusions concerning the glycoside-reducing effect of crystalline visammin that has been observed in three of these patients. Results obtained in the other two groups showed that improvement may still be obtained with crystalline visammin in many patients in whom nitrites or theophylline preparations are ineffective. Even doses as large as 300 mg. were well tolerated. Because of its almost specific spasmolytic effect on the smooth muscles of the coronary vessels, crystalline visammin is contraindicated in orthostatic disturbance of circulation, the symptoms of which depend on the failure of reflex-controlled capacity of circulatory adaptation but not on the spasm.

Life Expectation of Children with Congenital Heart Disease.—An attempt has been made to obtain information on all cases of congenital heart disease in children born in the years 1940-1949 to mothers residing in Birmingham, England. In 199,418 there were 633 cases of congenital heart disease. Diagnosis was confirmed at necropsy in 236, at operation for patent ductus arteriosus in 19, and by a consultant physician in 223. In the remaining 155, the diagnosis depended on the report of the school medical officer in 10 or on certification of the cause of death in 145. The 633 cases of congenital heart disease represented an incidence of 3.17 per thousand total births, and 3.23 per thousand live births. For the years 1940 to 1944, when ascertainment was more complete than in later years, the incidence was 3.62 per thousand total births and 3.73 per thousand live births. Estimation of life expectation at birth suggests that of 10 children with congenital heart disease born alive, 2 die by the end of the first week, another 1 or 2 by the end of the first month, and another 2 by the end of the first year. Between three and four survive to the 10th birthday. For the purpose of considering the frequency of association between malformation of the heart and other congenital malformations, the 145 cases recorded from the death register were excluded because of incomplete data. In the remaining 488, associated abnormalities were observed in 101 (21%). Thirty-one of these had mongolism. Of 18 with mongolism in whom the nature of the heart lesion was known, 14 had septal defects. Except for mongolism there was no noteworthy association of congenital heart disease with any other single malformation. Of the 633 children with congenital heart disease, 338 (53%) were boys. The percentages of males with various types of cardiac malformations were as follows: transposition of great vessels 72%, persistent common truncus arteriosus 47%, pulmonary stenosis 69%, coarctation of aorta 44%, septal defects 55%, and patent ductus arteriosus 39%. A slight predominance of men over women has generally been reported in the literature in series of grouped congenital heart defects.

Fate of Preserved Bovine Cartilage Implants in Man.—Gibson and Davis began to use implants of ox cartilage tentatively in 1948. The cartilaginous part of an ox scapula was obtained fresh from the slaughterhouse, cleaned of soft tissues and perichondrium, and cut into pieces of suitable size. It was then immersed in 1:4,000 thimerosal (Merthiolate) solution, which was slowly heated to the boiling point and maintained there for 10 to 15 minutes; the cartilage was found to warp badly if boiled rapidly. It was refrigerated until needed. At first ox cartilage seemed an excellent material either for skeletal support or for building up contours. No immediate reaction was seen in the tissues, and in only one case was the implant lost from sepsis, which was due to partial necrosis in the overlying flap. As time passed it was noted that most of the implants showed signs of absorption, and after 18 months some had disappeared completely. This progressive absorption of the bovine cartilage implants was also noted by other observers. Recently the authors made a follow-up study on 18 patients in whom they had used implants of bovine cartilage. Four patients could not be traced, in one the implant was lost early from sepsis, and one nasal implant was removed after three months and replaced by bone because the cosmetic result was unsatisfactory. Ten of the remaining 12 implants had been absorbed within two years. A second surgical implant in one case was found to be destroyed more rapidly than the first. Experimental implants in this case compared with controls showed on histological examination that a very marked systemic response to bovine cartilage had developed. This suggests that an antigen-antibody reaction might be responsible for the absorption. Experiments in human volunteers demonstrated that each successive implant showed greater absorption than the preceding one. Absorption occurs first by surface erosion, then by fibrous replacement, and later by dissolution of the cartilage, as the host's reaction increases. The antigenic activity of this relatively insoluble material is related to its surface area. The long survival of block implants, e. g., in a nasal bridge, is considered to be due not only to their relatively small surface area but also to their fibrous encapsulation. The observation that bovine cartilage of one batch may be absorbed much more rapidly than that of another to which the body has not become accustomed raises the question of whether the antibody is specific for a single breed of cattle or even for a single animal. Results in plastic surgery with bovine cartilage are likely to be disappointing.

Thoracic Duct Fistula.—Cummins reports the case of a woman, aged 45, with a normal convalescence following a thoracoplasty until the eighth postoperative day, when the wound was exposed for the removal of stitches. The wound was found to be elevated by a long, curved, sausage-shaped tumor that was fluctuant. Aspiration revealed a milky fluid, which was confirmed as chyle. A similar fluid was obtained by aspiration of Sembs' space anteriorly through the bed of the resected first rib. It was apparent that the thoracic duct had been injured during the apicolysis. About 30 oz. (940 cc.) of chyle were removed at the first aspiration. Daily aspirations of the wound region and Sembs' space were instituted, and the second stage of the operation was postponed. During the succeeding 13 days some 260 oz. (13 pt. or 6.1 liters) of chyle were removed by aspiration. At the second operation (three weeks after the first) about 1 qt. (1 liter) of chyle were evacuated; when the region of the fistula was mopped dry, the leak was apparent at the level of the arch of the aorta. Dissection revealed a complete tear of the main thoracic duct, with chyle dripping from the torn end of the caudal segment at the rate of 30 drops a minute. The leaking end of the duct was isolated and ligated, but a search for the other torn end was unsuccessful. The author believes that a shorter rather than a longer period of conservative treatment in the form of aspiration and diet is preferable in cases of chylous fistula. While no rigid rules can be laid down, the production of half a pint or more a day over a period of three weeks would seem to indicate that surgical intervention should be undertaken. Anastomosis to a vein has been successfully performed in some instances. Anastomosis of the cut ends of the duct or repair of the wall is also feasible, but these methods may be technically impossible as well as unnecessarily complicated. Tamponade of the region of the fistula may be required if the cut ends of the duct cannot be located. Since the thoracic duct has innumerable collateral communications with the lumbar intercostal and azygos veins, it has been suggested that the main duct should always be ligated in addition to any local treatment of the tributary. The third available procedure is ligation. This is the simplest method, and in the reported case proved to be effective.

Benign, Acute Osteitis of Spine in Children.—Bremner and Neligan observed seven young children with low-grade pyogenic osteitis of the lumbar spine. At the onset there were symptoms of a mild or moderate febrile illness and of a spinal lesion. Irritability, loss of appetite, and feverishness were noticed in most of the cases. Previously active children had stiff backs and spasms of pain and later objected to sitting or walking or even to being handled. These symptoms increased very gradually for up to five or six weeks and then became stationary or began to improve. The four children with the "hip syndrome" had a well-marked limp at the onset or within the first two weeks of illness. At the onset the ages of the patients ranged between 9 months and 2½ years. X-ray films of the lumbar spine showed narrowing of a disk space, with erosion of the adjacent margin of the body of either or both of the vertebrae bounding it. In one case there was also a posterior displacement of the upper of the two affected vertebrae. In two other cases the anteroposterior view showed an angular scoliosis at the level of the lesion. The children were treated by rest in a plaster bed; one patient was given penicillin in addition. They were allowed up without restriction of activity after periods ranging from 7 to 22 weeks. All remained well after follow-up periods of from 4 to 16 months. There is circumstantial evidence to suggest that the lesion is due to staphylococcic osteitis. The clinical picture strongly resembles that of tuberculous spondylitis. The distinction may be made by the tuberculin skin test, and be confirmed by the appearance of recalcification in the x-ray films within three months of the onset in the pyogenic cases. These children should be immobilized during the active stage of the disease, but activity can be permitted as soon as roentgenograms reveal recalcification.

Gold Therapy of Rheumatoid Arthritis.—Brown and Currie report studies of 220 arthritic patients, 38 of whom were treated with gold. Sixty were treated with copper, 60 with isotonic sodium chloride solution, 21 with arsenic, 22 with physiotherapy, and 19 with acetylsalicylic acid. The courses lasted 13 weeks. Diagnosis of rheumatoid arthritis was based on the criteria of polyarthritis, radiological confirmation or lack of evidence of other joint diseases, normal uric acid content of the blood, negative Wassermann reactions, negative gonococcal complement-fixation tests, negative serum agglutination test for brucellosis, acceptable clinical history and picture, increased erythrocyte sedimentation rate, and increased plasma viscosity. The patients were assessed for improvement at the end of the course, three months later, and one year after treatment. Subjective improvement was based on pain, performance, well-being, and appetite; objective improvement was assessed by joint measurements, erythrocyte sedimentation rate, plasma viscosity, and degree of anemia. The results obtained indicate that the effect of a single course of treatment with gold salts was no better than that of the other methods described.

Candida Peritonitis.—A man was hospitalized with foot-drop, fever, and abdominal pain. Later a wrist-drop developed, and signs of active carditis appeared. Studies did not reveal the cause. Penicillin was given, but bronchopneumonia developed. Because the patient was thought to have polyarteritis nodosa and despite the fact that he was known to have duodenal ulcer, he was treated with 100 mg. of corticotropin and 2 gm. of aureomycin daily. After three days of this regimen he complained of severe abdominal pain and his abdomen became distended. His condition did not permit surgical intervention, but 60 oz. (1.7 liters) of brownish viscid fluid was aspirated from the peritoneal cavity. Administration of corticotropin was stopped, and the stomach was aspirated. Dextrose in isotonic sodium chloride solution was given by the drip method and oxytetracycline (Terramycin) was also given intravenously. Three days later 100 oz. (2.8 liters) of fluid were withdrawn by paracentesis. Large numbers of Candida organisms were found on direct examination of the fluid, and a pure growth of Candida albicans was obtained on culture. Gentian violet was given daily by intraperitoneal injection. The patient died four days later. Necropsy revealed a perforated ulcer in the first part of the duodenum. The aureomycin must have altered the intestinal flora until C. albicans was dominant; when the ulcer perforated as a complication of treatment with corticotropin, this organism obtained access to the peritoneal cavity and set up the infection.

Diphtheria and Immunization.—An outbreak of diphtheria caused by Corynebacterium diphtheriae gravis in the urban district of Coseley and the surrounding districts of the administrative county of Stafford, England, is reported. There were 108 cases with 6 deaths during 1951 in a population of 267,250. An additional 31 persons were found to be harboring the pathogenic agent. In Coseley there had been for some years an incidence of diphtheria unusual in England since immunization became general. The outbreak was provided with fertile soil by the low level of immunity of the child population, and was not the result of development of a strain of C. diphtheriae gravis more than usually capable of overcoming the immunity produced by the ordinary diphtheria antigens. Long-term carriers appeared to play no part in the spread, and the large numbers of persons harboring the organism with slight or no symptoms were probably subclinical cases or transient carriers, being the result and not the cause of the outbreak. The infection was probably spread mainly at home rather than at school, although most of the cases were in school children. No explanation could be offered for the remarkable grouping of confirmed cases and of persons found to be harboring the organism in certain areas of Coseley. In the two districts most affected the incidence dropped immediately after mass immunization of the school population. The outbreak emphasized the importance of a constant watch on the proportion of children receiving reinforcement doses of diphtheria antigen, and showed that reliance on the figures prepared for the annual immunization return may be misleading, especially where school children are concerned. The outbreak occurred in an area in every district of which at least 73% of the school population had completed a course of immunization at some previous time. Although 49.1% of all the confirmed cases had some history of immunization, only 12% had been protected adequately within the preceding three years. Of the 22 patients with severe disease, only 7 (31.8%) had any history of immunization at all. Five of the six patients who died had never been immunized, while the sixth, an 8-year-old girl, had only a doubtful history of immunization in infancy. Thus further evidence was provided for the belief that the risk of severe illness or death is reduced for those who have at any time been immunized. The outbreak also demonstrated the greater willingness of the public to accept immunization when they are confronted with an outbreak of diphtheria.

Reduction of Postoperative Pain.—Pain is the chief factor preventing full respiratory excursions and adequate coughing after abdominal operations. In 30 patients between the ages of 31 and 78 who underwent abdominal operations with upper paramedian incisions, 4 cc. of a 2% solution of procaine hydrochloride was injected after closure of the peritoneum and before the patient left the operating room into the rectus sheath through polyethylene tubes, and 3 to 5 cc. of the same solution was injected by the same route every three hours for the next three days. All of the patients had considerable relief from pain a few minutes after the injection was given. The patients were able to carry out their breathing exercises unhampered by pain, movement in bed was facilitated, and ambulation was made more comfortable. Some patients found that passage of urine and flatus was much easier after the injections. There was no delay in healing or any evidence of wound infection. The necessity for postoperative narcotics was greatly diminished, and the incidence of postoperative pulmonary morbidity was reduced. The method was also found to be successful in midline incisions, the tubes being placed between the peritoneum and the linea alba.

Epidemic of Acute Nephritis.—An outbreak of acute nephritis in a sharply localized rural area is reported. Twenty-one of 22 cases of typical nephritis reported during the period from November, 1951, to February, 1952, were in persons under 17 years of age. There were two deaths from uremia. School and family illness records showed a very high incidence of sore throat during the winter. Throat cultures on 153 persons one month after the last reported cases of nephritis yielded 53 strains of hemolytic streptococci belonging to Lancefield's group A, Griffith's type 12. Carrier rates in the school and family groups were four times as high for those less than 17 years old as for the older group. These rates corresponded well with the incidence of nephritis and sore throat in the two groups over the winter period. Determinations of antistreptolysin O titers indicated recent infection with streptococci in most of those tested. The data presented lend weight to the generally held opinion that hemolytic streptococci play a part in the development of acute nephritis.

*Late Results of Pneumopericardium in Treatment of Exudative Pericarditis. G. Russo.—p. 14.

Late Results of Pneumopericardium in Exudative Pericarditis. —Late results are reported in seven cases of exudative pericarditis treated with pneumopericardium. Clinical, roentgenological, and electrocardiographic studies were made in four cases from 1 to 11 years after the treatment. Two patients who could not be seen because of a great traveling distance have confirmed by mail that they are well, and one died of acute miliary tuberculosis. The patients' ages at the time of treatment ranged from 15 to 63 years. The exudate was removed with a 50 cc. syringe to assure a slow removal and substitution of the gas for the exudate as this was being removed. In some cases the syringe was left in place for some time to permit complete emptying of the pericardiac cavity and to prevent even the temporary fusion of the pericardiac sheaths. The quantity of gas injected was individualized in each case, and attempts were made to establish a balance between the intrapericardiac and the atmospheric pressure. To prevent adhesive pericarditis, the injection of gas into the pericardium was continued long after all the exudate was removed, namely, until the clinical and roentgenological examinations indicated that the evolutional process was stopped and the inflammation had completely subsided. All the patients tolerated the treatment well, and there were no untoward effects to contraindicate continuation of the treatment. After the first tapping, there was always an improvement in the circulation, with decreased tachycardia, reduction or disappearance of dyspnea and precordial distress, and progressive decrease in the size of the liver. The drop in the venous pressure was always proportional to that in the pericardiac pressure. From five to eight tappings were sufficient for six patients. The other was a 22-year-old man who was hospitalized for one year and needed 58 tappings for removal of about 13 liters of exudate. After each tapping, 220,000 units of penicillin were introduced into the pericardium. At the time of writing three years later, the patient was well and had resumed his job as a carter. Streptomycin was used locally in the patients who were treated in the antibiotic era. This drug was given systemically with *p*-aminosalicylic acid to the patients with tuberculous forms and with sodium salicylate to those with rheumatic forms. The pneumopericardium, in addition to having immediate effects on the circulation and the course of the pericardiac inflammation, prevented all the late consequences of the disease. Adhesive pericarditis was avoided in all the patients. In the four who were followed there were none of the effects that the disease produces sooner or later on the cardiovascular apparatus, and the serous pericardiac layer was completely restored to normal. The author ascribes these excellent results to the fact that the gas refills were continued until the pericardiac and parapericardiac inflammation had disappeared and clinical and roentgenological examinations revealed that the anatomic condition was again normal.

*Corticotropin (ACTH) Treatment of Agranulocytosis. H. Schulten and W. Pribilla.—p. 503.

Corticotropin Treatment of Agranulocytosis.—Two women, aged 60 and 57, and a man, aged 53, with agranulocytosis due to drug hypersensitivity were treated with antibiotics and corticotropin (ACTH). Slight improvement in the general condition had resulted in the older woman from treatment with penicillin, but there was no definite improvement in the blood count. From the 15th to the 19th hospital day the patient was given, in addition to penicillin, 50 units of corticotropin daily. In the course of this treatment the number of granulocytes increased from 440 to 1,806 per cubic millimeter of blood, while the number of leukocytes first remained unchanged. Somewhat later the blood picture was restored to normal and a clinical cure was obtained. The older woman was treated with a penicillin-streptomycin preparation (Supracillin) and with corticotropin. There was rapid improvement in the general condition and in the blood picture in the course of this treatment. In the man, rapid improvement of the general condition, with drop of temperature and an increase in the leukocytes (from 1,900 to 10,500) with 82% granulocytes, resulted from treatment with aureomycin and corticotropin (50 units daily). The authors felt that the appearance of the leukocytes in the blood of the three patients was influenced by the administration of corticotropin. The evaluation of a therapeutic procedure in agranulocytosis is made difficult by the fact that this condition tends to resolve spontaneously when treated with antibiotics. The blood picture of the three patients did not show any significant change for several days during which they had been treated with antibiotics alone. This change occurred only after the administration of corticotropin. Treatment of agranulocytosis with corticotropin alone is contraindicated by the well-known fact that corticotropin reduces the general and local resistance of the organism to infection. This effect of the hormone is particularly undesirable in agranulocytosis. Its use in combination with antibiotics is sensible in agranulocytosis because of the control of inflammation exerted by the antibiotics and the increase in the number of granulocytes in the course of treatment with the hormone. It may be lifesaving in the short critical phase of the disease.

*Roentgenologic Phenomenon as Cause of Erroneous Diagnosis in Localization of Pointed Metallic Foreign Bodies in Gastrointestinal Tract. E. Kübler and S. Dortenmann.—p. 429.

Esophageal Ulcer in Severe Kyphoscoliosis.—Twenty-five patients with severe kyphoscoliosis were examined roentgenologically because of cardiac complaints or dysphagia. In two men and three women a peptic ulcer in the esophagus was detected. Esophagoscopy is not feasible as a rule in patients with severe kyphoscoliosis. In one of the five patients in whom it could be performed, it provided additional proof of the ulcer. In the remaining four patients there was no reason for proof by surgical intervention because the patients' symptoms were not suggestive of malignancy. The differential diagnosis had to be based on the roentgenologic findings alone. In most of the cases the ulcer niche could be demonstrated in a typical way as a contrast spot or by radiating folds on lateral as well as on frontal exposures. The localization of the niche always at the site of the greatest concavity was the strongest argument against diagnosis of a diverticulum. Traction diverticula of the esophagus had been described in the literature in cases of kyphoscoliotic, displacement of the esophagus, but they were always observed on the convexity of the lower third, while the ulcer was found exclusively in the middle third of the esophagus. This atypical localization and the unusually high incidence of the condition are closely related. It appears very likely that the middle portion of the concavity of the considerably angular esophagus presents a site of decreased resistance that may be considered as an "esophageal channel" under mechanical stress, in analogy to the "gastric channel" and its predisposition for ulcer. Additional factors, such as a topographically conditioned disturbance of the vascular and nervous supply, incipient peptic digestion due to aberrant gastric mucosa or a rise of the gastric juice resulting from insufficiency of the cardia, and an esophagitis associated with stenosis of the cardia, may contribute to the occurrence of the ulcer at this circumscribed weaker site of the wall much oftener than in an esophagus with a normal course.

Erroneous Roentgen Diagnosis of Gastrointestinal Perforation by Foreign Body.—Two women and a man who had swallowed a knitting needle and a sewing needle, a pin, and a nail, respectively, were examined roentgenologically to decide whether or not the pointed, metallic foreign body had perforated the wall of the gastrointestinal tract. The roentgenologic appearance suggested that in one of the women the knitting needle had perforated the wall of the stomach and the sewing needle that of the colon, and that in the other woman and in the man the pin and the nail had perforated through the wall of the stomach. Laparotomy was performed on all three patients but did not confirm the roentgenographic diagnosis. In order to explain the roentgenologic phenomenon that simulated perforation of the wall of the gastrointestinal tract in these patients, an attempt was first made to reproduce it in the stomach of human cadavers and of dead rabbits. This attempt in the atonic wall of the stomach failed. The phenomenon could, however, be reproduced in experiments made on the stomach of living rabbits. The shadows of the needles that were pressed against the inner wall of the stomach of the living animals were projected beyond the outline of the wall for as much as 1.8 cm., without, however, actually penetrating the wall; this was clearly demonstrated by use of graduated needles. The animal experiments showed that functional elements are the most important of the causes of the roentgenologic phenomenon simulating perforation, while the morphological changes in the tissues (thickening of the gastric mucosa and the finger-like extroversion of the outer layers of the gastric wall) contribute only secondarily to the clarification of this peculiar phenomenon.

Bone Marrow Culture in Purulent Meningitis.—The valuable information provided by bone marrow culture in typhoid fever and tuberculosis led to a trial of the method in various cases of purulent meningitis. Blood, bone marrow, and cerebrospinal fluid cultures and direct smears from 56 children from 10 days to 14 years of age were studied. At least one culture proved positive in all of the 44 cases in which the specimens were taken in the first days of the disease and before antibiotics had been used. Cultures from seven patients who had had the disease for several days before admission to the hospital and who had received antibiotics were negative. Cultures obtained on the 10th hospital day from five patients who had been treated with antibiotics for approximately one week and were considered cured also proved negative. The rich vascularization of the marrow and the delayed blood flow through its sinuses make it a focus of bacterial retention in which the pathogenic agent in any blood-borne infection can be found more easily than in the peripheral blood. The percentage of positive bone marrow cultures (61.3%) among the 44 patients who had not yet received antibiotics was much higher than the percentage of positive blood cultures (34%). Cerebrospinal fluid cultures in the same patients were positive in 59%, while the direct smears were positive in 65.9%. The pathogenic agents recovered in this series included Meningococcus, Streptococcus, Diplococcus, and Hemophilus organisms.

Chagas' Disease in Blood Donors.—A serologic study of Chagas' disease (American trypanosomiasis) was carried out on the blood of 536 prospective donors, selected at random at the blood bank of the Santa Casa de Misericordia of São Paulo, Brazil. Most of these persons came from the rural zone of São Paulo, where Chagas' disease is endemic. The survey was followed by complement fixation tests for diagnosis of the disease. Positive results were obtained in 22 persons (4.1%). The percentage of positive results is higher than that previously reported from other blood banks of São Paulo City, probably because the test was done in blood of persons from regions where the disease is endemic. The authors point out the danger of transmission of Chagas' disease in donor blood. They urge the complement fixation test as a routine practice in blood of prospective donors, especially if they live in zones where Chagas' disease is endemic. The test should also be made in persons who had had blood transfusions on the supposition that the disease might have been transmitted through transfusion.

Phlebotomy for Hemochromatosis.—It is known that only negligible quantities of iron can be excreted by the body, and that normally excessive absorption of iron from the intestine is prevented. In hemochromatosis there is probably a congenital defect in the mucosal block for iron. Consequently slightly more iron is absorbed than can be excreted, and the progressive accumulation of iron in the tissues is accompanied, usually at about middle age, by the characteristic pathological changes of the disease. It has been suggested that the rarity of hemochromatosis in women may be explained by the fact that iron is excreted in menstruation and pregnancy. Study of the age incidence of hemochromatosis lends some support to this hypothesis. Women get the disease later in life than men and almost always after the menopause. Investigating the ages of 202 male and 20 female patients reported on since 1935, Houston found that only two of the women were less than 45 years of age and that one of these two younger women had had amenorrhea for 13 years before dying of hemochromatosis at the age of 34. There is no way of removing iron from the body except by removing blood, which contains 500 mg. of iron per liter. A 39-year-old man with hemochromatosis proved by liver biopsy was bled by venepuncture a pint a week from Nov. 22, 1951, to July 3, 1952. Since July of 1952 a pint has been removed every fortnight. Throughout this period he has continued at work as an accountant, and at no time has he noticed any ill effects from loss of blood. To the time of writing 52 pints of blood had been withdrawn in 16 months. The author believes that such bleeding may reduce the enormous iron deposits and perhaps improve the prognosis. It might be adopted as the treatment of choice for all early cases, at least until sufficient data have been collected to enable its long-term effects to be assessed.

Growth of Bacteria in Infusion Fluids.—A dangerous reaction caused by bacterial growth in the fluid during intravenous infusion was observed by Michaels and Ruebner twice within two years. In both patients serious pyrexia developed while they received intravenous infusion therapy for several days, and in each case many coliform bacilli were found in the infusion fluid. The authors regard it as unlikely that the organisms were present in the fluid originally. In order to determine whether similar but less heavy, and therefore perhaps undetected, infection of infusion fluids occurred in hospital practice, the infusion fluids being administered to 32 patients were investigated. The fluid from the tubing was cultured within 48 hours after the infusion was begun in 19 cases, and within two to four days in 13 cases. All 32 fluids were found to be sterile. The authors also sought to ascertain whether coliform bacilli introduced into infusion fluids could multiply enough to perpetuate the contamination in the apparatus, even though a fresh uninfected bottle was substituted for a contaminated one. All the experiments were made at summer room temperature (about 20 C or 68 F). The organisms used were the coliform bacilli isolated from the aforementioned patients. It was found that considerable multiplication took place when crystalloid solutions such as Hartmann's fluid with 5% dextrose or isotonic sodium chloride solution were used, even if the bottles were changed. In cases of pyrexia of unknown origin in patients receiving intravenous therapy, a bacterial growth in the infusion set should be considered a possible cause. Attention is drawn to the importance of aseptic precautions in the administration of intravenous fluids. During a long-continued intravenous infusion the infusion apparatus and, if possible, the needle should be changed at least once every 24 hours.

Isoniazid in Treatment of Female Genital Tuberculosis.—Women with genital tuberculosis formerly received no active treatment, but since the advent of streptomycin and *p*-aminosalicylic acid, many attempts have been made to eradicate the disease with these drugs. Results have been disappointing because of the frequent reappearance of tuberculous follicles in the endometrium 6 or even 12 months after apparent cure. The effect of isoniazid alone and in combination with streptomycin and *p*-aminosalicylic acid was studied in 43 patients with tuberculous endometritis and 3 with tuberculous cervicitis; 40 showed no evidence of infection after treatment and one became pregnant. The permanence of these apparent cures can only be determined by follow-up at the end of a year or more, but the therapeutic value of the treatment is evident. The unique absence of caseation that characterizes tuberculous lesions in the endometrium probably makes them more responsive to antibiotic therapy than lesions in the fallopian tubes, where caseation is usually present. Relapse after treatment may be due to persistence of fallopian tube lesions, resulting in reinfection. All the patients received 150 mg. of isoniazid daily for 16 weeks; 11 were also given 1 gm. of streptomycin daily and 15 gm. of *p*-aminosalicylic acid daily during the last 8 weeks. No side-effects from isoniazid were noted in any of the patients, but streptomycin therapy was discontinued in one case after 30 gm. had been given, because the patient developed a rash and complained of weakness. Only four patients gained more than 4 lb. (1.8 kg.) in weight and none developed abnormal appetites. The patients were seen periodically throughout treatment, and at each visit the central nervous system was completely examined, the blood pressure and hemoglobin level were estimated, and total and differential white blood cell counts were made. No abnormalities were disclosed by any of these tests.

Hemorrhagic Diathesis Due to Absence of Christmas Factor.—The difference between Christmas disease and another hemorrhagic diathesis (hypoproconvertinemia) is illustrated by the case of a 10-year-old boy admitted to the Children's Clinic in Amsterdam. The first of many severe hemorrhages resulted from an injury at the age of 15 months, but even before this his parents had noticed that he was easily bruised. He was found to have a prolonged coagulation time and a diagnosis of hemophilia was made. His parents were healthy and no trace of a hemorrhagic diathesis could be found in the family. Tests on admission showed a greatly prolonged venous clotting time; normal bleeding time, clot retraction, fibrinogen content, and thrombocyte count; normal capillary resistance; and insufficient prothrombin consumption on coagulation. Various factors contradicted the diagnosis of hemophilia: 1. The patient's plasma in various dilutions exerted a normal coagulation promoting activity on the blood of a known hemophiliac whose coagulation time was greatly prolonged. 2. Normal plasma and the plasma of a person with hemophilia in the same dilutions caused the same reduction of the patient's coagulation time. 3. Intravenous injection of fraction 1 of Cohn (carrier of the antihemophilic factor) did not reduce the patient's coagulation time, whereas transfusion of normal plasma did, e. g., from 5 hours to 22 minutes after an hour. 4. In vitro the antihemophilic factor did not reduce the coagulation time. 5. The fraction active in hemophilia (which can be precipitated) had no effect on the patient's coagulation time, but coagulation was promoted by the supernatant fluid from which the fraction had been precipitated. The patient's condition was not hypoprothrombinemia, because his prothrombin time (Quick) and the prothrombin content were normal. It was not parahemophilia, because the prolonged prothrombin time of normal stored plasma could be reduced to normal by the addition to it of small quantities of his fresh plasma. It was not hypoproconvertinemia, because the determination of proconvertin in his plasma by Owren's method gave a value that was 60% of normal, his prothrombin time was normal, and the addition of a very small quantity of thromboplastin to his blood greatly reduced the coagulation time, which it does not do in hypoproconvertinemia or parahemophilia. These findings indicate that the patient's condition is characterized by a deficiency of a thromboplastin component differing from the one lacking in hemophilia. It now appears that factor 3, previously isolated by the authors from normal thrombocytes, the Christmas factor, and the antihemophilic factor all participate in thromboplastin formation.

Tolazoline and Cerebral Blood Flow.—The cerebral blood flow was estimated by the nitrous oxide method in six patients with mitral stenosis before and after intravenous injections of the vasodilator tolazoline hydrochloride. In the first two patients the cerebral venous blood was sampled through a cardiac catheter, the tip of which had been placed in the left superior jugular bulb under fluoroscopic control. In the remaining four patients, constant rate samples of blood were withdrawn from the superior jugular bulb and a peripheral artery by means of an electrically operated syringe device during inhalation of a nonanesthetic concentration of nitrous oxide for 10 minutes. At least 25 minutes between the first and second estimations were allowed for nitrous oxide desaturation: two to three minutes before the second flow was begun 20 to 30 mg. of tolazoline in 0.8 to 1.2 cc. were injected intravenously. Results showed a striking and significant decrease in the cerebral vascular resistance after administration of tolazoline, averaging about 25%; and an increase in the mean cerebral blood flow per unit weight of brain tissue of a similar order. These changes suggest that the primary action of tolazoline is vasodilatation, its effect on the cerebral blood flow being a function of its effect on the mean arterial pressure. It therefore seems reasonable to regard the action of tolazoline on the cerebral circulation as essentially histamine-like but differing from that of histamine in that effective cerebral arterial pressure is maintained with consequent increase in mean flow rates. Pending both the results of further investigations along these lines and controlled clinical assessment of the practical value of tolazoline, the authors suggest that the use of tolazoline in the emergency treatment of cerebral embolism in young patients with rheumatic heart disease is justified on theoretical grounds, since augmentation of the cerebral circulation by dilating the vessels and increasing the blood flow through them is clearly the aim of such therapy.

Modified Methimazole (Neomercazole) in Treatment of Thyrotoxicosis. — Neomercazole (2-carbethoxythio-1-methyl-glyoxaline) a modification of methimazole (Tapazole) was given a therapeutic trial in 120 patients with thyrotoxicosis who were followed for periods up to 21 months. Of the 120 patients, 30 received the drug as a preoperative medication and 90 as curative treatment. The optimum initial doses of the drug were 15, 30, and 45 mg. daily for patients with mild, average, and severe thyrotoxicosis respectively. Within two to eight weeks 93 became euthyroid and 27 responded more slowly. Nine of the latter group were operated on and the remaining 18 were controlled in three to six months. Goitrogenic reactions were avoided in all except seven patients by careful control of the maintenance dose, which varied from 4 to 20 mg. daily, keeping the basal metabolic rate between 0 and —10%. No toxic reactions were seen. Comparison of the author's results with those obtained with methimazole by other workers suggest that, weight for weight, neomercazole is at least as effective as, and very much less toxic than methimazole.

Electroencephalographic Evaluation of Anesthesia During Prolonged Surgical Interventions.—Various factors, such as operative shock, anoxia, and the accumulation of CO_2 in the blood, have been blamed for otherwise unexplained deaths during or immediately after surgical interventions. Although the exact mechanism by which such deaths are caused is not known, the brain is admittedly involved, either primarily or secondarily. Early detection of cerebral changes by encephalography during an operation may make it possible to apply a remedy before the resulting disturbances in bodily function become irreversible. Eleven patients undergoing intrathoracic operations lasting from four to five hours were kept under continuous electroencephalographic observation throughout the procedure. The tracings showed six simultaneous leads, and in every case a preliminary control tracing was made in the waking state. A combination of thiopental, nitrous oxide, and curare was used for anesthesia for all the patients, and the tracings confirmed the clinical impression that the period of induction is especially dangerous. Curare had no effect on cerebral activity, but induction of anesthesia with thiopental sodium, approximately 40 cg., prior to intubation produced profound changes. Large slow delta waves (1 to 2 cycles a second) appeared in all the leads for from 30 to 60 seconds, followed by abrupt extinction of the rhythm; the tracing resembled the picture presented after a generalized epileptic attack, a very severe closed skull injury, or in the moments immediately before death. This phase of complete extinction, which is variable in length, is followed by slow waves (2 to 3 cycles a second) and zones of extinction alternately, each lasting for from 5 to 10 seconds. The disturbed period varies in length from 1½ to 8 minutes. These findings clearly show the dangers accompanying the intravenous injection of barbiturates in large doses, and especially at a rapid rate; when the injection is given slowly, the changes are not the same. Electroencephalographic observation shows any variations that may occur in the depth of the anesthesia as the operation proceeds: deep sleep may be followed by periods in which the tracing is almost the same as that of the waking state. Undesirable variations of this kind seldom occur under skilled anesthetic management, but the absence of clinical signs makes it difficult to judge the efficacy of the anesthesia at all times. Changes in the tracings provide the earliest indication of cerebral distress. The difficult period of awakening is influenced by many factors that complicate the tracings, but signs of cerebral disturbances associated with recovery of consciousness can be detected.

Thrombosis of Internal Carotid Artery.—The angiographic aspect of the blood vessels of the cerebral posterior fossa has not been reported in the literature. The author reports a patient with the complaint of vertigo of nine years' standing. Two years previously he had a stroke that resulted in left-sided hemiplegia. A presumptive diagnosis of thrombosis of the internal carotid artery was made. Angiography was performed by injection of the opaque substance into the right subclavian artery. Three angiograms were made at intervals of two minutes. The first angiogram showed a thrombus lodged at the point of bifurcation of the internal carotid artery. The angiogram was typical for thrombosis of the internal carotid artery with visualized greatly dilated blood vessels, especially of the external carotid artery and its branches. The medium was seen entering the blood vessels of the posterior cerebral fossa, a small portion of the vertebral artery in the cervical region. The basilar, posterior cerebral, and posterior communicating arteries became visible. In the second angiogram the external carotid artery and its branches were no longer visible, whereas the blood vessels of the posterior cerebral fossa showed up very clearly, being principally the posterior cerebral artery and the cerebellar arteries. In the third angiogram the venous circulation of the posterior cerebral fossa was clearly visible. The mechanism by which blood vessels become visible in the posterior fossa when the opaque substance is injected into the right subclavian artery in thrombosis of the internal carotid artery is complicated. The author believes that in his case the increased blood supply to the right cerebral hemisphere through the enlarged anterior communicating artery was the reason for the improvement in the motor function experienced by the patient in the course of two years.

*Experiments with Some Antiseptics Proposed for Disinfection of Hands in Obstetrics. G. Massone.—p. 134.

Study of New Hand Disinfectants.—Test experiments are reported of the activity of three antiseptics for disinfection of hands. The new products were hexachlorophene (Gamophen), Desogen, a quaternary ammonium compound, and Dudolo, a fluid disinfectant consisting of an organic mercury compound to which *p*-chloro-*m*-cresol and *p*-chloroxylenol are added. A five minute scrubbing with the new soap and warm water had more effect than the usual 10 minute scrubbing with soap and warm water followed by a five minute disinfection in a solution containing 70% alcohol. With a 5% solution of Desogen the washing time was reduced to eight minutes of which the first three were used for scrubbing with soap and warm water. With Dudolo in a 1:1 solution the washing time was reduced to six minutes and in this case also the first three minutes were used for scrubbing with soap and warm water. Not only was the washing time shortened with the new products but their antiseptic action was more pronounced and lasted longer. When pilocarpine was used to stimulate sweating, the increase of the bacterial flora on the skin of the hands was much greater in persons who had used the common washing procedure. The most revealing data were obtained in another experiment. It is known that after lengthy operations microscopic defects are present in the surgeon's gloves and that bacteria can pass through them. Some persons wore gloves after washing their hands with the usual method and others after using the new products. They were then made to manipulate sterile material. One-half hour later a few bacterial colonies could already be discovered on the hands of the persons of the first group, and after two hours the number of these colonies had increased considerably. The number of colonies that appeared in the same period of time on the hands of the persons of the second group was much smaller. The positive features of the products were thus proved, although the author could not determine whether they were due to bactericidal or to bacteriostatic action. Except for Dudolo, these antiseptics must be used daily to obtain good results, but this does not contraindicate their use. In addition to their low cost and pleasant odor, these products do not have any toxic effect on the tissues.

Myasthenia and Pseudomyasthenia Reactions. A. Salmon.—p. 629.

Prophylaxis of Postoperative Vomiting.—The authors review the literature on the center of origin of postoperative vomiting and report results of a study made on 502 patients in whom surgery was performed under general anesthesia mainly for gynecological lesions. They divided the patients into three groups according to the premedication. The first group consisted of 65 patients in whom premedication was not practiced. The second group comprised 179 patients who were given alkalinizing agents during the day preceding the operation and 1 tablet of phenobarbital and 1 or 2 tablets of histamine-antagonizing agents in the evening. The third group of 258 patients received, in addition to the drugs given to the second group, one or two vials of Cortigen B_6 (each vial contained 12 units of an extract of total adrenal cortex in which epinephrine was not present and 50 mg. of pyridoxine). Glucose and ascorbic acid were also given to some patients of this group. There was vomiting in 16 patients of the first group (24%), 22 of the second (12.5%), and only 14 of the third (6%). There was nausea in 7.7%, 4%, and 3%, respectively. Although the alkalinizing and histamine-antagonizing agents were beneficial in preventing vomiting, better results were obtained when Cortigen B_6 was added.

*Possible Therapy of Undulant Fever with Oral Administration of Small Doses of Aureomycin and Intradermal Administration of Vaccine. M. Poli.—p. 946.

Aureomycin and Vaccine Therapy in Undulant Fever.—A 42-year-old man, who had had a low-grade fever for 47 days, complained of chills in the evening, pain in the right hypochondrium and muscles of the legs, anorexia, asthenia, headache, and night sweats. On hospitalization his serum was positive for Brucella melitensis. He was given orally 0.25 gm. of aureomycin daily in divided doses every six hours and intradermally polyvalent vaccine containing 10 million bacteria. This therapy was continued for 15 days, after which the vaccine was given alone for three more days. At the same time the patient received orally 0.50 gm. of chloramphenicol (Chloromycetin) daily for five days. This was given to alleviate a pain in the gallbladder area, since Escherichia coli had been recovered from the duodenum. The pain disappeared by the third day and the temperature had returned to normal by the fourth. A low-grade temperature reappeared nine days after the antibiotic therapy was discontinued. A second course of aureomycin was begun and continued for nine days. On the second day the temperature was again normal. A total of 6 gm. of aureomycin was given during the two courses. There were no untoward effects, although each injection of vaccine was followed by an intense local reaction with formation of a large papule. The erythrocyte sedimentation rate decreased rapidly, and the agglutination titer that at the time of hospitalization was 1:2,000 had become 1:4,000 on the fifth day and 1:8,000 on the 11th day. Thus while the antibiotic exerted a bacteriostatic action on the Br. melitensis organisms by arresting their development, the vaccine increased the antibody titer and thus enabled the organism to participate actively in the fight against the infection. Three months later the patient was in excellent general condition and had gained 10 kg. in weight. He complained of a pain in the gallbladder area and was given chloramphenicol orally.

DDT Intoxication in an Infant.—An infant born in a maternity hospital was placed in a bed in its home with bed clothing that had been heavily powdered with a material containing chlorophenothane (DDT) and pyrethrum. Anorexia, vomiting, diarrhea, muscular spasm, tremor, and mild renal and hepatic changes appeared. Chlorophenothane poisoning was considered the cause of the symptoms. Later, subcutaneous fat induration developed in the extremities and were diagnosed as subcutaneous neonatal adiponecrosis. Since these indurations could not be traced to trauma, it is assumed that these also were caused by chlorophenothane intoxication. After a period of hospitalization, the child was sufficiently improved to be discharged.

Neonatal Care of Infants of Diabetic Mothers. S. Joachimsson.—p. 546.

Diabetes Mellitus and Pregnancy.—Svanteson reports 15 cases of pregnancy with diabetes in 14 women. His principle of treatment is close control of the patient's diabetes and pregnancy, prophylactic cesarean section in the 36th week, and immediate transfer of the infant to the children's department of the hospital. Eleven mothers were delivered by cesarean section, one of them twice; three were delivered spontaneously, one with hydramnios and stillborn fetus in the 31st week, one with hydramnios in the 35th week, and one in the 36th week on admission for cesarean section. All the mothers survived. In two cases there was slight albuminuria and in one case marked retinopathy that disappeared during the pregnancy. The infants were without deformities.

*Prophylaxis and Therapy of Phlebitis with Heparin Given Intradermally. C. Olivier.—p. 503.
Gout with Rheumatic Symptomatology. J. Sérane.—p. 504.

Intradermal Administration of Heparin in Phlebitis.—According to Olivier, intravenous administration of heparin combined with oral administration of coumarin derivatives is the method of choice in the treatment of hospitalized patients with recent thrombosis of the deep veins. In certain patients who have recently been subjected to operations for venous thrombosis repeated injections of heparin into the subcutaneous network may prove undesirable. In patients treated at home at a considerable distance from large centers, only heparin may be employed because it does not require control determinations. This therapy frequently has to be discontinued before the patients have resumed walking because of painful reactions and the occurrence of hematoma at the site of the injection following repeated intravenous injections of heparin. The author treated 15 patients with thrombosis of the deep veins or with pulmonary embolism by injecting heparin into the healthy skin in an area not involved by edema, usually into the external aspect of the shoulder. The dose commonly used was 200 mg. in the morning and in the evening, i. e., 1 cc. of a pure 20% solution standardized at 100 I. U. per milligram without the addition of procaine hydrochloride or of a diffusion factor. The intradermal injections did not cause pain or hematoma at the site of the injection. Clotting time tests were carried out according to Lee and White's three tube technique. The test made before the first injection revealed in general that the clotting time was a few minutes less than normal. From the fourth to the eighth hour the clotting time was more than double the normal. This occurred regularly only on the second day of the treatment, suggesting that intradermal heparin therapy should be considered only for maintenance treatment. The thromboembolic disease did not become worse, and there was no recurrence. Hemorrhagic side-effects consisted of a spontaneous hematoma of the lower third of the rectus abdominis muscle in one patient on the 16th day after gastrectomy and five days after the dose of the heparin had been increased to 400 mg. twice a day, and of a parietal hematoma in an emaciated patient on the third day of treatment with doses of 200 mg. of heparin twice a day for pulmonary infarction. In the first patient the clotting time had been increased from 15 to 61 minutes and in the second from 12 to 65 minutes. A dose of 200 mg. twice a day may be employed in patients whose body weight exceeds 132 lb. (60 kg.), but caution is indicated in emaciated patients and on the day following an embolism.

Antibiotic Aerosols and Pulmonary Tuberculosis.—The concentration of antibiotics in the blood must not only be supplemented by concentrations in the tissues and the lesions if tuberculosis is to be treated successfully but must also be maintained at effective levels for substantial periods. Genuine, or stable, aerosols introduced into cavities and diseased bronchi should produce the favorable conditions obtained by surgical treatment, that is, bronchial disinfection and drainage combined with massive application of antibiotics to the cavity walls. Most of the efforts hitherto made in this direction have been only moderately successful, probably because the antibiotic was rapidly eliminated. The rapid declines in concentration noted in some reports could not have occurred if a truly stable aerosol with negatively charged particles of from 0.5 to 2 μ in size had been used. The authors found that *p*-aminosalicylic acid incorporated in an aerosol meeting these requirements did not appear in the blood until from three to six hours after aerosolization. It quickly attained a maximum level and then declined very slowly, showing that prolonged contact between the antibiotic and the tissues had been secured. Tests proved that the concentration of the antibiotic in the blood was greater than that obtained by oral administration and that it remained at a therapeutic level for a long period. Aerosol treatment properly used in combination with general antibiotic therapy may be expected to increase the percentage of antibiotic cures in pulmonary tuberculosis.

*Prolonged Sleep Treatment in Psychiatry. J. Bastié and A. Fernandez. —p. 651.

Systematic Detection of Tumors of Gastrointestinal Tract.—According to Albot and co-workers, systematic mass detection of tumors of the gastrointestinal tract has been practiced successfully for several years at the regional office of the Social Security Fund in Paris. To be economic and to yield significant results, systematic detection of the tumors depends on clinical predetection in stages. Selection of patients by systematic examination of all healthy persons with the aid of fluoroscopy, gastric intubation, rectoscope, and blood tests does not seem to be practicable. On the contrary, preliminary clinical detection by various medical teams has proved effective. The first selection is done by the roentgenologic examination of patients with dyspepsia or mild anorectal or intestinal disturbances who might have cancer; it is done by assistant social workers. The second phase of clinical detection is carried out by controller-physicians of social insurance funds, by plant physicians, and by the physicians of centers for systematic health examinations. It consists of eliminating from patients with minor disturbances suspected of having malignant lesions those whose condition is definitely benign, and sending those whose condition cannot be definitely ascertained to the detection center for tumors of the gastrointestinal tract. There, the third phase of clinical detection takes place. It is carried out by a team of specialists grouped around one or several experts at this center. It is on this "concentrated" group of patients that the technical and financial efforts of the detection center should be expended. Statistical data from 1946 to 1952 revealed that by this method the ratio of detected cancers as compared to the number of patients examined became much higher than with other methods of mass detection. Cancer was detected in 57 of 2,799 patients examined at the detection center for gastrointestinal tumors. Of these 57, 23 had cancer of the stomach, 23 cancer of the rectum, anus, sigmoid or cecum, 9 cancer of the esophagus and cardia, 1 cancer of the liver, and 1 cancer of the pancreas. This is a ratio of 20.3 per thousand, or one case of cancer detected among 50 patients examined, as compared to a ratio of 1 to 3 per thousand detected with other methods. Of 1,329 patients with anorectal disturbance who had a systematic rectoscopic examination, cancer of the rectum was detected in 18, i. e., a ratio of 13.5 per thousand. Seventeen of the 18 patients presented a long course that had not been recognized. Organizing procedures such as those reported by the authors are easy if full advantage is taken of all controls already exerted by social insurance, industrial medicine, and public health examinations. Combined with the findings from the detection center, they should be made available to all practitioners.

Prolonged Sleep in Psychiatric Treatment.—On the basis of Pavlov's concept of the internal inhibition of conditioned reflexes by sleep, the authors treated 10 women with various mental disorders by interrupted prolonged sleep. For the eight days preceding the sleep treatment the patients were given hepatic extracts, vitamins B_1, C, and P, sympathicotonic drugs, and psychotherapy. The patients were subjected to various examinations concerning the heart, the liver, and the kidneys. Treatment by sleep was instituted on the ninth day. Sleep was induced by hypnotics that affect the cerebral cortex, such as sodium bromide, chloralose, and morphine hydrochloride combined with scopolamine hydrobromide; the diencephalon, such as phenobarbital, aprobarbital diethylamine combined with barbital diethylamine, hexobarbital sodium, thiopental sodium; and the autonomous nervous system, such as Phenergan (10-[2-dimethylaminoisopropyl]-phenothiazine), diethazine (Diparcol) hydrochloride, and atropine. There is no uniform dosage scheme for the hypnotics. The dose depends on the type of the nervous system of the patient, his body weight, the nature of the psychopathic process, and the response to the treatment. The hypnotics were administered parenterally and orally five or six times daily at definite and regular hours. Hexobarbital sodium in doses of 0.50 to 1 gm. orally and thiopental sodium in doses of 0.50 to 1 gm. intravenously were used as "sleep starters." An average of 18 to 20 hours per 24 hours of deep or light but always reversible sleep, resembling physiological sleep, was maintained from 25 to 30 days. Only minor physiological changes were observed in the patients; sudden rises in temperature followed by sudden remission occurred once or twice in the course of the treatment; there were also alterations in the arterial blood pressure with a significant drop in the diastolic pressure in two patients with previous hypertension. Of the 10 patients, 4 (those with agitated remittent melancholia, obsessional neurosis, subacute ethylism, and psychic epilepsy) made a complete recovery, while the other 6 were temporarily cured or considerably improved. Protective inhibition of reflexes by sleep may be induced without great risk. It provides the cortex with prolonged rest that makes possible establishment of new regulating mechanisms for the subcortical-cortical connections and better restoration of the balance of the exhausted organism.

Insulin Therapy in Multiple Sclerosis.—Six patients with typical multiple sclerosis were given insulin subshocks. The insulin injection was given in the morning before breakfast, with an initial dose of from 5 to 15 units of insulin. This was increased daily by 5 or 10 units to a maximal dose of 40 to 60 units or rarely 80 units. The injections were given daily or every other day, with rests on Sundays, up to 15 or 25 injections. The subshock was allowed to last for 1 to 3 hours without reaching the precoma or coma phase. The subshock was discontinued at the end of 3 hours by giving the patient sugar, tea with 100 gm. of sugar, alone or with an intravenous injection of from 10 to 30 cc. of a 40 or 50% hypertonic dextrose solution. Relapsing subshock symptoms were likewise controlled by administration of sugar in an orange-flavored drink, food, and sweets. These doses of insulin produced neurosympathetic symptoms that did not approach precoma or coma phases. The treatment was well tolerated, without accidents or complications. In two cases the treatment was repeated several months after the first for consolidation of good results. In all cases the appetite, nutrition, and general condition of the patients improved. Pain, paresthesia, spasticity, and ataxia were greatly diminished. The patients reported a sense of well-being, which lasted for several months. The treatment is symptomatic. Its palliative or curative effects seem to be due to the stimulating action of insulin on the hepatic functions and on the protection of myelin.

*Rubeolic Embryopathy: Report of Two Cases. E. Miralbell-Andreu. —p. 135.

Congenital Defects Due to Rubella.—Two cases of congenital defects due to rubella are reported. Both infants were born to normal couples who had no familial history of malformations or of congenital cataract. The mother of the first infant had rubella in the first two weeks of her first pregnancy. The infant was seen at the age of 2½ months, and a diagnosis of unilateral congenital cataract of the central type was made. The infant was otherwise normal and had normal hearing. The mother of the second infant had the rubella in the sixth week of her third pregnancy. Her other two children are normal. The infant was seen at the age of 3 days. A diagnosis of bilateral congenital cataract of the central type and of congenital heart disease was made. The nature of the infant's heart disease has not been determined. His hearing is normal. The author advises that gamma globulin be given to a woman who is exposed to rubella in the first trimester of pregnancy. The prophylactic action of the drug lasts 30 days. If any further contact occurs after 30 days, the treatment should be repeated. Induced or natural rubella immunization is not effective.

Electromyographic Diagnosis of Myasthenia. F. Thiebaut, F. Isch, and C. Isch-Treussard.—p. 3.
*Epilepsy Caused by Cerebral Tumors (Based on 170 Cases of Epileptogenic Tumors). J.-E. Paillas, J. Bonnal and J. Corriol.—p. 18.

Epilepsy Caused by Cerebral Tumors.—Analysis of 170 cases of epileptogenic tumors showed that epileptic symptoms were most frequent between the ages of 31 and 50 (58%). Epileptic seizures in a child believed to have a cerebral tumor suggest that it is supratentorial, because tumors of the posterior fossa, though frequent in early childhood, rarely cause epilepsy. Epilepsy in an adult is most likely to be neoplastic in origin when it appears after the age of 31. Temporal and frontal tumors account for 60% of the cases of epilepsy in this series; next most frequent as a cause of epilepsy are median and paramedian tumors of the convexity of the hemispheres. The incidence of epilepsy is proportional to the benignity of the tumor; 92 of the tumors causing epilepsy were benign. Generalized grand mal seizures occurred in 66 cases, and were the first symptom of the tumor in 46 patients. Temporal epilepsy, which had the highest incidence (41%), was also often the first sign of a tumor. A true jacksonian seizure or a localized clonus, though the first epileptic manifestation in 31 cases, was the first sign of the tumor in only 21. The value of the various types of seizure in localizing the tumor is limited, because the focus functionally responsible may be distant from the tumor site. Electroencephalographic study showed irritative waves indicative of epilepsy in only 25% of the cases of malignant tumors and only 37.6% of the cases of benign tumors. Epileptic seizures may recur after surgical removal of a cerebral tumor either because the character of the tumor made complete removal impossible or because faulty technique resulted in formation of excessive scar tissue.

*Correlations and Reciprocal Influence of Epinephrine and Nor-Epinephrine on Physiopathology of Circulation: Observations on Man. S. Bardelli and R. Monfardini.—p. 467.
Cystic Emphysema in Bronchopulmonary Neoplasms. R. Miceli.—p. 470.

Effect of Arterenol and Epinephrine on Physiopathology of Cardiovascular Apparatus.—Arterenol diluted in 50 cc. of isotonic sodium chloride solution was given intravenously to 10 patients with no cardiovascular abnormalities in doses of 0.1 mcg. per kilogram of body weight per minute for 20 minutes. Five other patients in the same cardiovascular state received the drug intramuscularly in doses of 0.30 mg. An increase in both systolic and diastolic blood pressures followed in all the patients, and there was also pronounced bradycardia. The drug was well tolerated; the only complaint was a slight headache and constriction in the neck, which became more or less swollen. Two days later the same 10 patients were given intravenously a mixture consisting of equal doses of epinephrine and arterenol. The other five patients received a mixture of equal doses of the two drugs intramuscularly. The systolic and diastolic pressures increased to a lesser degree than when arterenol had been given alone; in some instances the values remained unchanged. There was also a lesser degree of bradycardia. Side-effects, when present, were much milder. The vasomotor action of arterenol was thus decreased by that of epinephrine. This seems to prove the hypothesis advanced by Goldenberg that there is in the human organism a hemodynamic equilibrium that is governed by a ratio between these two substances that are in some respects antagonists. An alteration of this ratio because of epinephrine deficiency leads to vasospasm and thereafter to hypertension.

*Lysergic Acid Ethylamide, a New Antipsychotic Drug with Strong Sedative Effect, Obtained from Ergot; Preliminary Report. H. Solms.—p. 356.

Lysergic Acid Ethylamide, a New Antipsychotic Drug.—Twenty-seven subcutaneous injections of lysergic acid ethylamide, a half-synthetic ergot alkaloid, were given to eight normal men. The dose varied from 0.25 mg. to 0.2 mg.; the average amount administered was 0.5 to 0.75 mg. Two distinct phases of the effect of the drug could be distinguished. The first phase of 15 minutes duration was characterized by benign neurovegetative irritative and sensomotor symptoms and by mild discomfort such as occasional salivation, secretion of tears, sweating, ataxia, hyperreflexia, and paresthesia. There was occasional nausea, heavy breathing, and sensation of vibration and tension in the muscles. The second phase of one and a half hour duration was one of psychosis, with a sudden onset of personality changes and simultaneous disappearance of discomfort. The psychopathological aspect was that of a schizophrenia-like condition of asthenia, indifference, and disturbance of volition, with intensive phenomena of depersonalization without sleep. A mild hallucinosis syndrome resulted on nine occasions from injections with higher doses, and in five instances it was associated with exaggerated impulses, decreased inhibition, and unmotivated laughing. The after effect of a single injection of lysergic acid ethylamide consisted of deep night sleep, occasional fatigue, and mild weakness of concentration and memory. Twenty chronic patients with schizophrenia and oligophrenia were given 402 applications of lysergic acid ethylamide, either 0.25 to 1 mg. subcutaneously or 0.5 to 1.5 mg. (one to three tablets) by mouth three times daily. Sedation of paranoid-hallucinatory excitation resulted for one to four hours; hallucinations did not subside but became milder. The patients became apathetic and more indifferent to their illusions. Several patients received 0.25 to 0.5 mg. subcutaneously daily for two weeks and six weeks, respectively, as a continued sedative during the day, with the result that perception was retained but apperception was abolished. Occasionally patients with acute catatonia who had become accustomed to high doses of morphine-scopolamine and barbiturates reacted promptly and favorably to doses of 0.5 to 1 mg. of lysergic acid ethylamide, but in general lysergic acid ethylamide was not sufficient in severe excitation, and the limit of tolerance was usually reached by increasing the dose from 1 to 2 mg. Lysergic acid ethylamide proved to be an effective soporific, inducing sleep for three to five hours in patients with schizophrenia and oligophrenia who were suffering from long-continued disturbances of sleep or mild restlessness during the night. The effect of 0.3 to 0.5 mg. of lysergic acid ethylamide subcutaneously or of 2 tablets of 0.5 mg. orally equaled that of 1 to 3 gm. chloral, 0.8 gm. of sulfonmethane, or 0.5 to 1 gm. of barbital sodium. The effect of the lysergic acid ethylamide on the paranoid-hallucinatory condition of excitation in schizophrenic patients is that of a reversible "chemical lobotomy." The drug is a new type of sedative that belongs neither to the hypnotics or narcotics of barbituric acid or morphine type nor to the sympathicolytics or parasympathicolytics with a predominantly blocking effect on the autonomic nervous system.

Unilateral Polycystic Kidney. J. E. Marcel.—p. 1351.

Acute Thrombopenic Purpura with Autoagglutination.—Serologic study of the blood of a woman, aged 30, with acute thrombopenic purpura showed previously unreported phenomena of agglutination and destruction in vitro of normal platelets and inhibition of normal clot retraction. Her illness began on Dec. 14, 1951, with general feverish malaise, followed a week later by petechiae on the backs of the hands and slight gingival bleeding. The purpuric manifestations increased and the temperature, which had returned to nearly normal levels, rose again to 39 or 40 C. Pallor indicated the rapid development of intense anemia. No source of infection was found, and careful study of the patient's history failed to show foreign toxins of any kind; in particular, there was no habitual use of hypnotics. The only factor of interest was a subfebrile episode with monocytosis and pronounced acceleration of the erythrocyte sedimentation rate some months earlier. The impossibility of determining the etiology of this purpura with anemia led to the institution of treatment with antibiotics and whole blood transfusions, but the patient's condition deteriorated and she died on Jan. 11, 1952. Autopsy was not permitted. Addition of the patient's serum to suspensions of normal platelets in their own citrated or heparinized plasma resulted in their rapid agglutination and destruction. Clot retraction was completely inhibited when the serum was added in equal parts to whole blood or citrated and recalcified plasma. This inhibitory action, however, took place only when calcium was present. A diagnosis of immunologic thrombopenic purpura with autoagglutination was strongly indicated, but could not be confirmed.

*Value of Blood Picture as Indicator of Damage Caused by Irradiation. H. Langendorff.—p. 408.

*Comparison of Effects of Roentgen and Radium Irradiation on Human Skin. F. Wachsmann.—p. 438.

Blood Picture as Indicator of Irradiation Damage.—In an attempt to determine the tolerance of the organism to irradiation with the aid of blood studies, 30 rats were given irradiation treatment with 2.5 r daily for one year. The other technical factors were 92 kv., 10 ma, 0.5 mm. aluminum filtration, focal-skin distance 80 cm., and daily irradiation time of 13 seconds. Eight of the 30 animals died, 6 of these between the 44th and 52nd week. The white blood cells, particularly the lymphocytes, were studied in 1,574 blood smears. The blood for the differential blood count was withdrawn from the vein of the tail at weekly intervals. The spleen and the testes removed from the animals who died spontaneously and from others who were killed when in a dying state were examined microscopically. Weekly counts of the leukocytes and particularly of the lymphocytes did not show any changes that might have indicated damage due to irradiation. As contrasted with these observations, the histological appearance of the tissues from the testes and spleen showed that these organs had been moderately damaged. Many of the seminal tubules of the testes did not contain any spermatozoa, while spermatoblasts were frequently present in large numbers. Spermatogonia were also present in large numbers. The changes in the spleen consisted of a reduction of the lymphatic tissue, deficiency of some of the germinal centers, and some increase of the erythropoietic tissue. There is evidence that this irradiation damage may be compensated intensively by the regenerative capacity of the blood-forming tissue, the testes and the spleen and that Jacobson's protective humoral factor may be considered significant with respect to the spleen and the hematopoietic system. As a result of his experience, the author states that the blood picture has only limited value as an indicator of irradiation damage after the application of small doses of irradiation for long periods.

Effects of Roentgen and Radium Irradiation on Human Skin.—An attempt was made to compare the effects of roentgen irradiation with that of radium-gamma irradiation. The skin of the thigh of patients with carcinoma and the skin of pigs were exposed to roentgen rays using a tension of 45 to 200 kv., and to radium-gamma rays under such conditions that distribution of the dose with respect to space and time was equal as much as possible, i. e., the size of the field, the relative depth dose and the dose rate were all equal. The "built-up effect" on which an increase of the depth dose of the ultra-hard rays depends was excluded by interposed tissue-equivalent filters made with Trolitul (a type of varnish). Equal doses thus were applied to the irradiated skin. Results showed that in order to produce the same erythematous reaction of medium degree twice as much radium-gamma irradiation dose is required as roentgen ray irradiation. Furthermore it was demonstrated that the "dose-equivalent" of the radium-gamma irradiation depends on the dose, i. e., that with small doses (erythema threshold) approximately three times as much gamma irradiation, and with large doses (epitheliolysis up to necrosis) approximately two to one and half times as much gamma irradiation has to be applied in order to elicit the same skin reaction as with roentgen irradiation using a tension of 45 to 200 kv. It is emphasized that this lesser effect of the radium-gamma irradiation applies only to the human skin and the skin of pigs; it may be explained only by the specific ionization density of roentgen and radium-gamma irradiation.

Hypopotassemia with Hypertension Due to *p*-Aminosalicylic Acid.—The occurrence of hypopotassemia in association with cardiovascular hypotension in a 60-year-old man with chronic bilateral fibrocaseous tuberculosis who had received 27 gm. of streptomycin and 1,008 gm. of sodium *p*-aminosalicylic acid is reported. Following two days of severe vomiting and diarrhea, muscle weakness developed gradually. He was afebrile, with a pulse rate of 70 to 80 per minute. Blood pressure was 140/80. No abnormal murmurs or changes in heart sounds were detected, but an occasional premature beat was heard. The serum potassium level was 10 mg. per 100 cc. The electrocardiogram showed a Q-T interval of 0.5 second. The cerebrospinal fluid pressure was normal, the potassium content of the cerebrospinal fluid being 12 mg. per 100 cc. Since the patient could tolerate a full diet, no additional potassium therapy was given. Serial serum potassium estimations showed a gradual rise and in two days power was obviously returning to the paretic muscles. Two weeks after admission to the hospital full power was present in the trunk and limbs. The blood pressure was 210/110 mm. Hg, the serum potassium level was 20 mg., and the electrocardiographic recordings were normal. It is suggested that the low serum potassium was due to diarrhea and vomiting, the frequent accompaniments of treatment with *p*-aminosalicylic acid, and that the hypotension resulted from the primary myocardial effect of the low-serum potassium. Since many patients are treated at their homes with *p*-aminosalicylic acid, often without close supervision, particular attention should be paid to this toxic complication.

Glycosuria and Hyperglycemia Following Treatment with *p*-Aminosalicylic Acid.—Robel observed elevation of the blood sugar curve in a number of patients who were treated with *p*-aminosalicylic acid. In most cases the hyperglycemia was reversible, but in one case he noticed a more pronounced glycosuria following *p*-aminosalicylic acid therapy and found that after administration of the drug was discontinued and even after glycosuria subsided the fasting blood sugar curve was persistently elevated despite a diabetic diet. The patient died 11 months after cessation of treatment with *p*-aminosalicylic acid, and the hyperglycemia persisted until death, the average fasting blood sugar value being 180 mg. per 100 cc. The history of the patient suggests that prolonged administration of *p*-aminosalicylic acid is capable of producing irreversible changes in the insular apparatus of the pancreas and that it is advisable that fasting blood sugar determinations be made in addition to the usual tests performed during prolonged treatment with this drug, such as differential blood cell counts, determination of hemoglobin value, and urinalysis. Ambulatory treatment with *p*-aminosalicylic acid is inadvisable in view of the possibility of the development of complications. The reported case recalls similar cases reported by Tempini and Franke in which prolonged administration of *p*-aminosalicylic acid resulted in permanent injury to the insular apparatus of the pancreas.

Frequency of Concurrence of Diabetes Mellitus and Tuberculosis.—In the course of roentgenologic examination of 2,962 patients with diabetes mellitus, Siedhoff discovered that 7.6% had pulmonary tuberculosis. Reports in the literature indicate that the incidence of tuberculosis in diabetic patients varies from 2 to 8.4%. The two diseases concur more frequently in men than in women. The 2,962 diabetic patients observed by the author included 1,158 men, of whom 12.2% had tuberculosis, and 1,804 women, of whom 4.8% had tuberculosis; the ratio of men and women was 2.5:1. In the literature it has been estimated that tuberculosis is from 5 to 10 times as frequent in diabetics as in the general population. The author found that in 1950 in West Berlin tuberculosis was four times more frequent in diabetic patients than in the general population. This patient material was unusual, since the incidence of tuberculosis had increased during World War II and the blockade in 1949. Following the lifting of the blockade in 1949 new cases and recurrences of diabetes increased considerably, particularly among women.

Penicillin Treatment of Erysipeloid. A. Ladehoff.—p. 409.
Hematuria After Cystoscopy with Rodalon Solution in Bladder. W. P. Sperling.—p. 412.

Effect of Mersalyl in Pulmonary Stasis of Cardiac Origin.—Marquardsen and his associates consider the administration of mersalyl a rational treatment in pulmonary stasis due to cardiac insufficiency. Of their 16 patients, 5 men and 11 women, aged from 48 to 79, 14 had myocardial degeneration on arteriosclerotic or hypertensive basis and two had mitral stenosis. In nine there was no peripheral edema, six had slight edema, and one patient had marked crural edema. From three to six injections of mersalyl or thiomerin were given, in the dosage of 2 ml. twice weekly. Treatment also included light rest in bed and restricted fluid and salt intake. In most of the cases there was loss of weight accompanied by increased vital capacity, usually with subjective improvement. The results seemed to be more certain in cases without peripheral edema. Measurements of the vital capacity were made by means of a pocket spirometer. The increase in vital capacity occurred within from five minutes to one hour after the injection.

Training of Patients with Radial Paralysis. J. Thernøe.—p. 462.

Pulmonary Complications in Dysphagia.—Disorders localized in the throat may cause defective swallowing and overflow with aspiration of food and secretion from the esophagus to the air passages and lead to pulmonary symptoms, often with roentgenologic changes. Compression of the trachea due to goiter may cause tracheitis, from which a constant discharge gives rise to and maintains pulmonary symptoms. A further possibility for the origin of pulmonary complications in dysphagia is bronchial compression or involvement in esophageal dilatation or tumor. The pulmonary affection in dysphagia may be bronchitis, pneumonitis, fibrosis, inflammatory bronchostenosis, abscess, or empyema. Jepsen believes the syndrome to be considerably more frequent than the literature suggests. Eleven cases are reported, four of which are described in detail. The pulmonary affection usually appeared as a roentgenologically demonstrable infiltration, as a rule localized to the right lung. After treatment of the cause of the dysphagia, the pulmonary infiltrations sometimes receded. In most cases they failed to regress in spite of recovery from the primary disorder; in such cases fibrosis was believed to be present. By and large three groups are represented: (1) patients having pulmonary complications without manifest dysphagia, (2) patients having dysphagia without manifest pulmonary complications, and (3) patients with borderline cases. The first group is especially important, as acquaintance with the syndrome affords a possibility for earlier diagnosis and treatment of the primary disorder. The pulmonary symptoms connected with the dysphagia may at times be so marked that the dysphagia symptoms are forced into the background and are not mentioned by the patient except on close questioning.

*Dye-Stuffs Used in Coloring Foods: Question of Cancerogenesis. A. Wingler.—p. 134.

Cancerogenic Effect of Food Coloring.—Wingler points out that the increasing mechanization of food processing has led to the increasing use of coloring matter and other chemicals in foods. He discusses legal regulations existing in different countries with regard to the use of chemicals in foods, giving particular attention to the efforts made by German physicians to restrict and regulate the use of chemicals and coloring matter in foods. At the convention of German surgeons in 1949 a resolution was passed that basic food stuffs should not be colored, and in 1950 a committee was formed by the German research association to study the coloring of basic foods, in which coloring was not legally prohibited. The committee lists substances that thorough investigation has established as harmless, including among others certain "natural" coloring substances such as carotin, chlorophyll, and lactoflavin. The possible cancerogenic effect of substances used for the coloring of food stuffs has disturbed physicians ever since Japanese investigators in 1936 reported the development of tumors in rats that had been given dimethyl-amino-azobenzene, also known as butter-yellow (because of its use in the coloring of butter and fats). Procedures used in the testing of coloring substances that might prove cancerogenic are described and substances suspected of being cancerogenic are listed. In addition to prolonged feeding experiments on animals, the committee recommended studying coloring substances that are suspected of being cancerogenic with regard to the formation of Heinz bodies in the erythrocytes of cats. Dye-stuffs used in cosmetics and chemicals used in drinking water are likewise being investigated. The committee's chief object is to promote the collaboration between the industry that produces and uses the coloring substances, research bodies aiming to establish their harmlessness, and the legal authorities, so that the use of chemicals in foods will not be harmful to the consumer.

BOOK REVIEWS

J. Meller Ophthalmic Surgery: A Handbook of Surgical Operations on the Eyeball and Its Appendages. With supplement by K. Kofler. Translated and edited by Ray K. Daily, M.D., F.A.C.S., and Louis Daily, Jr., B.S., M.D., Ph.D. Sixth edition revised and enlarged by Professor Dr. J. Böck. Cloth. $12. Pp. 529, with 287 illustrations. Blakiston Company (division of Doubleday & Company, Inc.), 575 Madison Ave., New York 22, 1953.

The descriptions of various operative procedures are concisely and clearly written and are amply illustrated with drawings and photographs. With the gradual improvement in the technique of dacryocystorhinostomy, the indications for the classical Meller technique, however, are gradually becoming fewer. In the chapter on cataract surgery, the statement "Whoever has had experience of performing very many extracapsular extractions, with almost no complications, even in cases with quite immature cataracts, will naturally have but little inclination to change a reliable technique for a more daring procedure" gives the impression that the author prefers the extracapsular technique of cataract extraction. Like most European ophthalmic surgeons, he omits the retrobulbar injection and the generally accepted preplaced or postplaced corneoscleral sutures. The postoperative medication is brought up-to-date by the translators.

In view of the recent advances made with contact lenses and other optic aids, surgery of high myopia is no longer advisable because of its inherent risks and complications. Posterior sclerotomy preceding any definitive operation on an eye with a very high intraocular pressure is inadvisable, particularly since the use of hyaluronidase (in the procaine hydrochloride) in retrobulbar injection, produces practically the same result. In the chapter on corneal transplantation, the complications of slipping of the corneal disk and formation of anterior synechia are seldom encountered today. The more desirable method of edge-to-edge suturing of the graft to the recipient cornea permits early reformation of the anterior chamber.

This edition, like its predecessor, should be a preferred book on surgery of the eye, particularly with regard to operative procedures around the lids and for the classical Meller operation. The translators are to be congratulated on their magnificent piece of work and for the editorial notes that bring the text into more modern focus.

Handbook of Treatment of Acute Poisoning. By E. H. Bensley, M.B E., B.A., M.D., Director, Department of Metabolism and Toxicology, Montreal General Hospital, Montreal, and G. E. Joron, B.A., M.D., C.M., Junior Assistant, Department of Medicine and Department of Metabolism and Toxicology, Montreal General Hospital. Cloth. $2.50. Pp. 201. Renouf Publishing Company, Ltd., 2182 St. Catherine St. W., Montreal 25, Que., Canada, 1953.

This book was prepared as a guide to treatment of acute poisoning for physicians without special experience in toxicology and as a basis for instruction of students in the health professions and in first aid courses. It is divided into two sections, the first of which is devoted to basic principles, a general plan for treating acute poisoning, and discussions of individual methods of treatment. The second section describes common types of acute poisoning, with instructions for managing the patient' before and after arrival of the physician. Brief notes on collection and preservation of samples for chemical analysis, a list of items for an emergency poison kit, and a brief list of recommended books on toxicology are presented in the appendix.

The authors state that, since the book is intended primarily as a guide to treatment of the acute poisoning emergency, certain aspects such as medicolegal problems, chronic intoxications, and the late consequences of acute intoxication are either avoided or mentioned incidental to the main discussion. No attempt is made to thoroughly cover agricultural, industrial, or household chemical products capable of causing injury, although a number of the commoner ones are indexed and grouped with related compounds with which the reader may be more familiar. Dosage recommendations are for adults, and the reader is advised to make appropriate modifications of doses when treating infants and children, with the warning that special care must be exercised in the use of morphine and picrotoxin for such patients. Small children, however, are the most frequent victims of accidental poisoning. Unfortunately, there is little reliable published information on dosages for children, and physicians must rely on experience or resort to empirical dosage rules based on age and weight. Since acute poisoning emergencies frequently call for special dosages, such information should be available in a treatment primer.

Renal Cortical Necrosis and the Kidney of Concealed Accidental Haemorrhage. By H. L. Sheehan, D.Sc., M.D., F.R.C.P., and H. C. Moore, M.D. Publication number 167, American Lecture Series, monograph in Bannerstone Division of American Lectures in Circulation. Edited by Irvine H. Page, M.D., and A. C. Corcoran, M.D. Cloth. $7.75. Pp. 186, with 64 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill., [n.d.].

Renal cortical necrosis is a rare, though serious, condition seen frequently after an obstetric complication variously called premature separation of the placenta, abruptio placenta, or uteroplacental apoplexy. In all instances the fetus is killed by the hemorrhage within the uterus, and too frequently the mother dies of renal cortical necrosis from spasm of the renal vessels. In the past there have been several conjectures as to the cause of the condition; this led the authors to make a careful study of 67 autopsied cases.

The results of pathological examination of the kidneys and other organs in the 67 cases form the basis of the book. In many instances the autopsy was performed within two to five hours after death, and special precautions were taken to minimize the effects of pressure or distortion in removal of the organs. There are a number of excellent photomicrographs of kidney sections showing all stages of change, from cloudy swelling to spasm, to thrombosis and later healing. Correlative clinical and histological analysis made it possible for the authors to postulate with considerable certainty the sequence of events in renal cortical necrosis. Damage to the kidney takes place very quickly after the onset of the uterine hemorrhage. Initially, there is spasm of the malpighian glomerulus, which is followed after a few minutes to five or more hours by complete cessation of blood flow to the glomerulus. After this period, a relaxation of spasm takes place, and blood recirculates. When there is a short period of spasm, minor changes are seen in the tubules and other portions of the kidney. Cases of this type are mild, showing proteinuria and casts, and the kidney soon returns to normal function. Severer cases have a secondary spasm of a part of the intralobular artery and progress to renal cortical necrosis. Between these extremes there are many clinical and pathological types. When the spasm relaxes, blood flows to the parts and is promptly thrombosed, thus arresting all further circulation to the part. Release of the spasm within the first two or three hours after the original stoppage of blood flow will prevent gross renal lesions from developing. The authors give no hint as to the probable cause of the original spasm.

The book is well written and readable. The 14 chapters cover the important phases of the condition and, to an adequate extent, related conditions. A full bibliography and an excellent index make it possible to find references in both the literature and the book. It is written primarily for specialists in obstetrics and pathology, and it should be favorably received as a much-needed work in a previously obscure area of information.

The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

Morris' Human Anatomy: A Complete Systematic Treatise. Edited by J. Parsons Schaeffer, A.M., M.D., Ph.D. Contributors: Leslie B. Arey, et al. Eleventh edition. Cloth. $16. Pp. 1718, with 1220 illustrations. Blakiston Company, 575 Madison Ave., New York 22, 1953.

This well-known textbook of anatomy continues to bear the name of its originator, Sir Henry Morris, a distinguished surgeon and teacher, born and educated in England, a president of the Royal College of Surgeons, a member of the General Medical Council, one of the founders of the Imperial Cancer Research Fund, a president of the Section on Anatomy and Histology of the British Medical Association, and an honorary member of the Medical Society of the State of New York. Sir Henry was editor of the first, second, and third editions and coeditor of the fourth edition with J. P. McMurrich of the University of Michigan. From the 5th edition through the 9th, the editor was C. M. Jackson of the University of Michigan, who was followed by J. P. Schaeffer of Jefferson Medical College for the 10th edition and the present edition. Many other authorities, both British and American, have contributed sections to the various editions. New contributors are Ernest Lachman, who collaborated with Raymond F. Blount in preparation of the section on the digestive system; J. E. Markee, author of the section on the urogenital system; C. G. Smith, who collaborated with J. C. B. Grant in revising the section on the musculature; and Mildred Trotter, who with Robert J. Terry rewrote and revised the sections on osteology and the articulations. The other contributors to this edition are the same as in the preceding edition.

Many illustrations have been replaced with new ones, and illustrations have been added, including a number of roentgenograms. To keep the text within a single volume, some items have been set in smaller type and made up in double columns for easier reading. Much investigation remains to be done in anatomy. Recent studies in this field have made certain previous descriptions untenable, and it becomes necessary from time to time to rewrite and revise. That has been well done in this volume. A better grade of paper and less of the smaller type would have contributed to ease of reading.

Die Lungenresektionen. Von Prof. Dr. A. Lezius, o.ö. Professor der Chirurgie an der Universität Hamburg, Hamburg. Mit einem Geleitwort von Prof. Dr. R. Nissen, Director der chirurgischen Universitätsklinik Basel. Cloth. 49.80 marks. Pp. 143, with 149 illustrations. Georg Thieme Verlag, Diemershaldenstrasse 47, (14a) Stuttgart-O; agents for U. S. A., Grune & Stratton, Inc., 381 Fourth Ave., N. Y. 16, 1953.

This is the first of a series of monographs dealing with thoracic surgical problems. Radical surgical extirpation is stressed as the treatment of choice in neoplasms of the lung; however, no such specific therapy can be recommended regarding inflammatory lesions of the lung. Specific indications for removal of a lung, lobe, or segment still differ. It is important, nevertheless, to standardize techniques for such procedures before results can be properly evaluated according to the test of time. The author has also included short, terse sections on diagnosis, indications, and preoperative and postoperative care; these factors cannot be thoroughly separated from operative technique.

Only one of such great experience and unusual technical skill could state that a standardized technique of pulmonary resection does not exist. Techniques are altered by the temperament and dexterity of the surgeon as well as by the numerous physiological anomalies that continually plague, yet stimulate, him. The techniques described are based on the author's experience with 1,000 cases. It is refreshing to note that, in this day of many gadgets, he uses no special armamentarium, since he believes that success of the operative procedure depends on the head and hands of the surgeon rather than on instruments.

The art work by Ingrid Schaumburg is outstanding. These beautiful illustrations reveal the close collaboration that must exist between author and artist if the "feel" of the operating room is to be truly depicted. This book is an outstanding example of authoritative teaching and brillant presentation. It is recommended to anyone interested in lung resections.

The Epidemiology of Health. Iago Galdston, M.D., editor. New York Academy of Medicine Book. Cloth. $4. Pp. 197. Health Education Council, No. 10 Downing St., New York 14, 1953.

Epidemiology is an old discipline that has been associated, in the minds of physicians, with disease and its control. Epidemiology of health is a startling term to the casual reader, but the members of this symposium, referring to history, have shown that for centuries there has been an epidemiology of health as well as an epidemiology of disease. This positive concept expressed in the phrase "a healthy mind in a healthy body" and in the concept of health "as physical, emotional and spiritual well-being rather than mere absence of disease" has been a long-sought goal.

This volume records 15 papers that were the subject matter of the Eleventh Annual Eastern States Health Education Conference. The concept of a positive epidemiology of health is discussed by well-informed physicians in terms of its history and evolution and the way it is currently applied to health practice in the Army, in industry, in tuberculosis, in mental hygiene, in nutrition, and in some of the newer concepts such as geriatrics, preventive medicine in private practice, and public health and health education.

This stimulating book should be read by physicians who are concerned with the attitudes that are developing toward disease and the relation that medical practice has to such special fields as preventive medicine, public health, and the care of the healthy. The foreword is by Howard R. Craig, director of the New York Academy of Medicine, and the first chapter is by Iago Galdston of the New York Academy of Medicine, who also served as editor for the symposium.

Archiv und Atlas der normalen und pathologischen Anatomie in typischen Röntgenbildern: *Einführung in die Enzephalographie (Pneumenzephalographie).* Von Dr. med. habil. Otto Schiersmann, Dozent für Neurologie und Psychiatrie, Chefarzt des Krankenhauses Bethesda, Wuppertal-Elberfeld. Ergänzungsband 64, Fortschritte auf dem Gebiete der Röntgenstrahlen vereinigt mit Röntgenpraxis, herausgegeben von R. Grashey, et al. Second edition. Cloth. 36 marks. Pp. 135, with 192 illustrations. Georg Thieme, Diemershaldenstrasse 47, (14a) Stuttgart O; agents for U. S. A., Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1952.

This is the second and enlarged edition of an introductory monograph on pneumoencephalography that first appeared in 1942. The book deals first, briefly, with the anatomy of the ventricular system and the intracranial subarachnoid spaces and the physiology of the cerebrospinal fluid. Various means of filling the ventricular system (ventricular, suboccipital, and lumbar puncture) and the different contrast media employed in visualizing the ventricular system are discussed. The author prefers the injection of air by the lumbar route, although he has used the suboccipital route extensively. The technique of obtaining satisfactory films and their interpretation occupy the remainder of the text. The illustrations are satisfactory.

This little monograph is truly introductory and cannot be compared to the much more thorough presentations of the subject. There is an index and an extensive bibliography. The latter would be far more useful, however, if the German practice of presenting the references one immediately after the other were abandoned for the arrangement of the authors' names in a column.

Lust-Pfaundler-Husler Krankheiten des Kindesalters: Ihre Erkennung und Behandlung in der Praxis. Von Prof. Dr. Josef Husler, Chefarzt des Kinderkrankenhauses München-Schwabing. Nineteenth edition. Cloth. 29.80 marks. Pp. 700. Urban & Schwarzenberg, Thierschstrasse 11, München 26; Meinekestr. 13, Berlin W. 15, 1953.

Professor Husler has revised and edited this edition somewhat after the plan followed by the editors of Osler's "Practice of Medicine." The volume is in three parts. The first is a survey of the entire field of pediatrics, including diseases of the newborn and infections in the growing child. The second part deals with diagnosis and treatment from the technical viewpoint. Part 3 concerns methods of feeding, including diets auxiliary to milk. There are 155 pages devoted to alphabetic listing of drugs and discussions of poisoning. Special attention is given to congenital defects in the heart and circulatory system, to virus pneumonias, and to the use of antibiotics, including contraindications. This comprehensive book will be useful to general practitioners who read German.

Office Orthopedics. By Lewis Cozen, M.D., F.A.C.S., Assistant Professor of Orthopedic Surgery, College of Medical Evangelists, Los Angeles. Second edition. Cloth. $5.50. Pp. 304, with 191 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1953.

This book actually covers the whole field of orthopedics, at lease with reference to diagnosis. Cases that would be treated in the office have a much more extensive diagnosis and differential diagnosis, while those that would of necessity be hospital cases are mentioned briefly, since these should not be considered a part of office practice of orthopedics. Many of the procedures mentioned can be done in the office if the necessary equipment is at hand; however, a considerable amount of such work is usually done at the hospital.

This edition is up-to-date with regard to treatment and refers to many new methods or new drugs that have been announced within the last six months. While most of the outlined treatment is generally accepted, all of the suggested methods of treatment are not universally accepted, and several are definitely controversial. Many of the drawings and illustrations are borrowed from other books or texts, so that there is a great deal of review rather than original work. This book is chiefly for physicians doing general surgery or in general practice who need a ready reference to office orthopedics; however, the descriptions in the book are inadequate for its use as a textbook of orthopedic surgery.

Gout and Gouty Arthritis. By John H. Talbott, M.D., Professor of Medicine, The University of Buffalo School of Medicine, Buffalo, New York. Modern medical monographs, 7. Cloth. $4. Pp. 92, with 32 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1953.

This monograph is the result of 20 years of laboratory investigation on uric acid metabolism and clinical study of gout. The more recent biochemical advances in this field are recorded, with emphasis on clinical aspects.

Most of the phases of gout are covered briefly. Of particular interest is the discussion of intermediary metabolism of uric acid, which includes a review of the precursors of uric acid, the miscible pool, and turnover rate of labeled uric acid. Of equal interest is the section on concentration of urates in serum and renal exchange of urates. A discussion of probenecid (Benemid), a uricosuric agent, is well presented. The remainder of the material covers symptoms, diagnosis, and treatment of gout.

While the roentgenograms are good, their value would have been enhanced if photographs had been included to coincide with the various roentgenologic phases. The bibliography is fairly comprehensive. The material is accurately presented, although the theory that a liberal intake of protein has no effect on the course of this disease is not entirely acceptable. The book is well written, easy to read, and is highly recommended to those interested in gout and gouty arthritis.

Lind's Treatise on Scurvy: A Bicentenary Volume Containing a Reprint of the First Edition of a Treatise of the Scurvy by James Lind, M.D., with Additional Notes. Edited by C. P. Stewart, Ph.D., D.Sc., and Douglas Guthrie, M.D., F.R.C.S.E. [Originally printed by Sands, Murray, and Cochran, Edinburgh, for A. Millar, in the Strand, London, 1753.] Cloth. 45s. Pp. 440, with 4 illustrations, Edinburgh University Press, Old College, South Bridge, Edinburgh 8 [sole agent: Oliver & Boyd, Ltd., Tweeddale Court, 14 High St., Edinburgh 1], 1953.

Although this book was published 200 years ago to demonstrate that scurvy could be prevented and cured, it is still surprisingly modern in outlook and in literary style. Lind's treatise on scurvy not only led to the virtual disappearance of the disease in civilized communities, but through its presentation of the subject, with censure of muddled thinking and superstition, emphasis on careful observation and controlled experiment, and reliance on facts and rational interpretation of them, it has attained recognition as one of the great medical classics of all time. The reprinting of this book, together with additional notes giving a short biography of Lind and a summary of the present status of vitamin C, pays tribute to a man who received little attention during his life. This is an eminently readable book and deserves careful study.

Patients Are People: A Medical-Social Approach to Prolonged Illness. By Minna Field. Cloth. $3.75. Pp. 244. Columbia University Press, 2960 Broadway, New York 27; Oxford University Press, Amen House, Warwick Sq., London, E.C.4, 1953.

Many years experience as a social service worker in a large chronic disease hospital (Montefiore Hospital, New York) form the background of this author. She has found that the problems of chronic illness are complex from all points of view, medically, socially, and psychologically. Montefiore Hospital for many years has acted as a sort of a laboratory in trying out new methods of caring for the patient with a long illness. For instance, the home care now carried on in many cities was initiated at Montefiore Hospital in 1947. How to handle the rapidly increasing number of chronically ill and aging patients as a family or community problem still defies adequate solution; therefore, many methods must be tried out on a pilot scale for the next several years. It would be a mistake, as the author points out, to set up a rigid over-all scheme on a national level at this time. The many facets of this gigantic medicosocial problem are competently and dispassionately discussed. This book should be read by all who are interested in human aspects of chronic illness.

Die geburtshilflichen Operationen: Ihre Ausführung und Anwendung, ein Lehrbuch für Studenten und Gebrauchsbuch für Ärzte. Von Prof. Dr. Med. Heinrich Martius, Direktor der Universitäts-Frauenklink Göttingen. Seventh edition. Cloth. 34 marks. Pp. 290, with 268 illustrations. Georg Thieme Verlag, Diemershaldenstrasse 47, (14a) Stuttgart-O; agents for U. S. A., Grune & Stratton, Inc., 381 Fourth Ave., N. Y. 16, 1953.

In spite of the fact that successive editions of books on operative procedures become larger and contain more illustrations, this one is not larger than the last and contains 13 less illustrations. This is because modern operative obstetrics has become simplified, and several surgical procedures have become obsolete. The changes in this edition are not many, presumably because operations in obstetrics have not changed much, nor have there been any significant surgical advances in obstetrics. This small book is full of excellent advice concerning the indications for, and the technique of, practically all obstetric operations. The vast experience of the author as a practicing obstetrician and as a teacher is evident throughout the book. The illustrations are clear, instructive, and numerous. For anyone who can read German, this book is highly recommended.

Food for Your Heart: A Manual for Patient and Physician. By Department of Nutrition, Harvard School of Public Health, Harvard University, Boston. This manual has been reviewed and endorsed by Council on Foods and Nutrition, American Medical Association. Paper. 25 cents. Pp. 48. American Heart Association, Inc., 44 E. 23rd St., New York 10, 1952.

The busy physician pressed for time to explain the "whys" and "wherefores' of necessary diet restrictions to his patients with cardiac conditions will welcome this booklet of the American Heart Association. Useful facts and practical directions are presented in simple, nontechnical language easily understood by the average patient. Tables of the sodium content of foods and water supplies are included in the appendix. This manual, prepared by the Department of Nutrition at Harvard University, has been reviewed and accepted by the Council on Foods and Nutrition of the American Medical Association.

Einführung in die pathologische Physiologie. Von Professor Dr. Max Bürger, Direktor der medizinischen Universitätsklinik Leipzig, Fourth edition. Cloth. 42 marks. Pp. 561, with 193 illustrations. Georg Thieme, Thomaskirchhof 21, (10b) Leipzig, C. 1, 1953.

Impressive both in appearance and in content, this book covers thoroughly the field of functional disturbances of the various systems of the body. The author assumes that his readers are solidly grounded in anatomy, physiology, and biochemistry, but he provides a wealth of illustrations, tabular data, and chemical information for the benefit of those whose command of these subjects is weak or not up-to-date. The broad pages are not easy to read; a two column page would be preferable. There is a good index. The book can be recommended as comprehensive, scholarly, and modern.

QUERIES AND MINOR NOTES

TREATMENT OF HYDROFLUORIC ACID BURNS

To the Editor:—*Please give an opinion on the use of "triple dyes" and calcium gluconate locally for the treatment of hydrofluoric acid burns. I have had misgivings about the routine use of calcium gluconate in such places as the finger tips, especially when the burns are believed to be mild.*

John E. Maley, M.D., Ann Arbor, Mich.

Answer.—The following treatment is based on the experience of a consultant who, over a four year period, observed from 10 to 20 burns a week of varying degrees caused by hydrofluoric acid of varying strengths. The treatment as finally elaborated produced no deformities, disabilities, or compensation losses over more than two years. Such a program involves prompt treatment with water at the place where the accident occurred and removal of the patient to the medical department, where judgment is made as to the extent of further treatment necessary. The success of this treatment lies in the emphasis on meticulous care during the initial stages. This experience has resulted in a refusal to make a judgment as to definitive treatment until at least 24 hours have elapsed. In essence, the treatment consists of immersion in water (never a neutralizer) for not less than 30 minutes and up to four hours. This is followed by application of packs saturated with glycerin, which are changed every four hours. On the second day, the burns can be classified as to whether further damage will occur or only dressing changes will be needed for a day or two. Because hydrofluoric acid has a tendency to prolong its action on the tissues for four or five days, in contrast to other acids, this decision on the second day is extremely important. The patient is always given the benefit of any doubt about whether the burn is progressive. If the decision is made that the injury could result in a second or third degree burn, further treatment consists of meticulous cleansing of the areas involved according to surgical standards and use of the compression techniques described by Blair, Koch, and Mason. Ample quantities of finely powdered tantalum oxide is blown on the area with special apparatus. The tantalum oxide powder has no bacteriostatic or bactericidal properties, but, on the other hand, it cannot possibly enter into a chemical reaction with any of the body tissues or fluids. It is, therefore, as nonirritating a dressing as could be used. In addition, a physical factor is involved in its use in that this powder, which has been passed through a 400 mesh screen, has enormous surface area and creates tremendous capillary attraction when applied to oozing wounds. Any such oozing creates a tough, nonirritating cover when tantalum oxide is used. The dressing applied on the 2nd day by the compression technique is not removed until the 9th or 10th day.

This consultant stopped using calcium gluconate injections locally, because, in the majority of his cases, such injections contributed to sloughing, which resulted in the need for plastic surgery in many cases. Burns underneath the finger nails present a distressing problem because of the physician's tendency to delay treatment in the hope for spontaneous improvement. It is far better to do a fairly radical removal of the distal third of the nail whenever a patient complains of pain in that region than to procrastinate in the hope that the pain will go away. Such surgical removal of the nail gives immediate relief. In eye burns, initial treatment with water for not less than four hours will prevent injury if such treatment can be started within 15 to 30 minutes after the acid has entered the eye. Under no circumstances is the use of any neutralizing solution advocated. The use of triple dyes was discarded by this consultant more than 20 years ago. There are much better ways to promote wound healing than by the use of antiseptics of that nature.

CORTISONE OR CORTICOTROPIN IN RHEUMATIC FEVER

To the Editor:—*Is it wise to give cortisone or corticotropin (ACTH) to all patients with acute rheumatic fever?*

M.D., Utah.

Answer.—Determination of the exact phase of rheumatic fever during which administration of cortisone or corticotropin can be expected to produce best results has not been achieved. Effects observed from use of these hormones in rheumatic fever are as follows: suppression of fever, amelioration of polyarthritis, slowing of tachycardia, improvement of the "toxemia," improvement of appetite, lowering of the erythrocyte sedimentation rate, improvement of atrioventricular conduction, improvement of anemia, and restitution to normal of abnormal levels of blood proteins. Much time will be required before a determination can be made of the effects induced by these hormones on eventual cardiac lesions. Important observations reported since announcement of the original discovery include the following ones: properly administered, these hormones may cause reduction in the size of the heart; if withdrawn prematurely, reactivation of the rheumatic process may occur; recurrences are not prevented; preexisting organic murmurs are not abolished; signs of pericarditis, with or without effusions, may disappear rapidly; chorea, when present, has been observed to disappear promptly; subcutaneous nodules may soften, diminish in size, or disappear during periods of administration of these compounds; congestive heart failure accompanying acute rheumatic fever may improve; and in some instances, cardiac murmurs associated with dilation of the heart disappear rapidly. The latter effects may result from the anti-inflammatory effect of cortisone or corticotropin on the myocardium, and thus, congestive heart failure is not a contraindication to the use of these hormones.

With these principles in mind, general rules may be suggested on which to make decisions about use of cortisone or corticotropin in treatment of rheumatic fever. It seems reasonable that these hormones be used in instances in which attacks are severe, that is, when fever is notable, when joints are considerably swollen and painful, when tachycardia is present, the leukocyte count is elevated, and electrocardiograms disclose disturbances of conduction. Either cortisone or corticotropin should be administered in acute rheumatic fever in adequate doses and should be given for at least four to six weeks, if possible. Consideration should be given to the metabolic disturbances these hormones induce. Salt intake should be limited, adequate amounts of proteins should be made available, and precautions should be taken to prevent excessive gain in weight due to a large intake of calories. When the time arrives for withdrawal of cortisone or corticotropin, this should be undertaken slowly rather than abruptly. The dose should be lowered by decrements of 12.5 to 25 mg. of cortisone or 15 to 10 units of corticotropin. If signs appear suggesting that the disease is becoming reactivated, the dose should again be increased for periods of several days to several weeks. Subsequently, the amount administered should again be gradually reduced. In general, before administering cortisone or corticotropin to a patient with acute rheumatic fever, the physician should observe the patient for a few days. The attack may clear spontaneously, that is, febrile temperatures may return to normal, rapid pulse rates may become slow, elevated leukocyte counts and sedimentation rates may return to normal, and toxicity and arthralgias may disappear with little treatment other than bed rest.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

ABORTIONS AND EXPOSURE TO LEAD

To the Editor:—*A patient has just had her second spontaneous abortion, both at three and one-half months gestation; the first occurred in June, 1952, the second in March, 1953. During her second pregnancy, she was taking prophylactic Proloid (a thyroid preparation) and diethylstilbestrol. Her last menstrual period occurred Nov. 4, 1952. She had no symptoms of abortion until the event took place with typical bleeding and cramps. She has been working with lead styphnate and butyl acetate since November, 1950. Could there be any connection between the abortions and the patient's exposure to these chemicals?*

M.D., New York.

Answer.—Lead could have induced the abortions, provided sufficient exposure occurred, but it is recognized that other causes could have operated in bringing them about. If this patient has resumed work, it may prove possible to appraise the extent of exposure. Since lead styphnate commonly is handled in small quantities and sometimes wet, determination of lead in the general workroom atmosphere may be without value. The exposure, if any, is likely to be sharply local and may represent "hand-to-mouth" transfer, even though gloves may have been worn. Particularly if this patient has resumed work, but even if she has not, the urinary level of lead should be determined. In addition, although it is not a conclusive test, examination for cellular stippling on a quantitive basis should be done, and the basophilic aggregation test should be conducted. If other persons are engaged in identical work, some or all should be tested for lead in the urine and blood; however, negative results in other employees may not be significant, since exposure may have been strictly individual. Exposure to lead on the part of the husband would be significant and should be determined.

EXTRASYSTOLES

To the Editor:—*A 40-year-old physician has had ventricular extrasystoles for five years. Complete examination has not revealed any pathological condition. Electrocardiograms made by different cardiologists show the extrasystoles to be irregular in frequency (every 4, 6, or 12 beats) and especially strong in the supine position. There have never been signs of myocardial damage. The gastrointestinal tract was examined roentgenographically, with no abnormal findings. The patient's activities are undisturbed; however, these premature beats have become annoying, and the patient has to take 3 grains (0.19 gm.) of quinidine three or four times a day to eliminate them. As soon as he stops treatment, they return. 1. Can quinidine in this amount be taken without harm over a long period? 2. If the heart becomes refractory to quinidine, what other drug can be used? 3. Will this condition cause, in the long run, any other cardiac disturbance? 4. What else besides quinidine and psychotherapy might be of benefit to him?* *M.D., New York.*

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—1. Quinidine can be taken over an indefinite period without cumulative toxic effects, other than the acute effects that can result from overdosage. 2. The use of quinidine is not characterized by the development of refractory states. It is unlikely that the patient's heart will become refractory to it. 3. There is no definite evidence that extrasystoles of the type described cause myocardial damage or any other cardiac disturbance leading to shortening of life expectancy. 4. Other suggestions, in addition to use of quinidine and psychotherapy, that might be helpful include (*a*) the use of a mild sedative, such as barbiturates and bromides; (*b*) abstinence from use of coffee, strong tea, cola drinks, and tobacco, any one of which may aggravate extrasystoles; in addition, extrasystoles may be aggravated in some patients by various forms of alcoholic beverages, whereas in other patients these factors seem unimportant; (*c*) it is suggested that these patients make a point of getting at least eight hours sleep at night so that they are not unduly nervous from chronic fatigue.

Answer.—The problem of ventricular extrasystoles is frequently encountered. 1. Quinidine taken in amounts of 3 grains three or four times daily can be taken without harm over such a long time, especially since this patient seems to have experienced none of the usual disagreeable sensations following its prolonged use, such as tinnitus, vertigo, and nausea. Commonly, 1 grain (0.06 gm.) taken three to five times daily will be found as effective as the larger doses mentioned. 2. There is a possibility that after prolonged use quinidine will lose its effectiveness; however, discontinuing use of the drug for one month usually restores its effectiveness. 3. In this consultant's experience, premature ventricular contractions on a nonorganic basis have not resulted in myocardial damage. Such an arrhythmia, however, if projected over a long period, frequently becomes progressively aggravated and more refractory to management. 4. Most premature ventricular contractions (extrasystoles) have an activating, exciting, or instigating factor. In this case, the gastrointestinal tract was found normal on several roentgenographic examinations; however, other sources of infection must be ruled out, notably the gallbladder, nose, throat, mouth, and teeth. More important is a careful study of the patient's habits. Tobacco is a frequent cause of ventricular extrasystoles. Alcohol, strong coffee, and tea are frequently responsible. Pent-up emotions, worry, and fear are common causes, in which case the proper management is psychiatric plus the use of mild sedation in conjunction with quinidine.

EMERGENCY TREATMENT OF ADRENOCORTICAL INSUFFICIENCY

To the Editor:—*In Queries and Minor Notes in* The Journal *March 7, 1953, is a discussion on cortisone administration, in which it is stated that when certain conditions of stress ensue in the wake of previous cortisone therapy the drug be readministered to counter effects of suppressed adrenocortical function. Severe intercurrent infection is mentioned as such a stress situation. I have gained the impression from published reports of animal experiments that minor infections may become overwhelming in the presence of cortisone. If this is the case, it occurs to me that in the presence of infection another form of substitution therapy might be more beneficial. Can you clarify this for me?*

Roger D. McKenna, M.D., Madison, Wis.

Answer.—In the event of increased stress, such as might be caused by severe infection, burn, a surgical procedure, traumatic injury, hemorrhage, or other form of shock, the patient who also has adrenocortical insufficiency must be supplied exogenously with an adequate quantity of adrenocortical hormones. This applies whether the adrenocortical insufficiency is temporary, as in the case of rheumatoid patients who have been receiving cortisone, or permanent, as in Addison's disease. At present, the most expeditious way to supply such patients with adrenocortical hormone usually is to administer cortisone; extra salt and desoxycorticosterone also are necessary in some cases of sodium and chloride depletion not adequately managed by the administration of cortisone alone. If the patient has been receiving corticotropin the dose may be increased during the period of stress, if the adrenal cortexes are capable of responding; however, administration of corticotropin alone does not constitute adequate emergency treatment of adrenocortical insufficiency when the adrenal cortexes are temporarily atrophic, since several days of stimulation by corticotropin may be required to achieve adequate production of adrenocortical hormones. The dosage of cortisone is of greatest importance in this problem. Grossly excessive doses, such as were used in the animal experiments probably referred to in the query mentioned, do interfere with the normal reaction of tissues to infection; however, doses in the range of the body's requirement for the particular stress do not impair but rather strengthen the body's defenses. Unfortunately, the exact requirement of adrenocortical hormones at any one time cannot be precisely determined in advance; doses must be adjusted to fit the varying circumstances in the case. In general, doses of cortisone between 100 and 200 mg. per day have been found effective in preventing adrenocortical insufficiency in the event of most stresses and have been employed during the relatively brief course of severe acute infections without apparent aggravation of the infections. Even larger doses may be used for short periods, if needed to prevent adrenocortical insufficiency. Appropriate specific treatment for the infection, such as antibiotic therapy, chemotherapy, or surgical drainage, should be instituted. As these measures bring the infection under control, the dose of cortisone should be reduced gradually. Current information does not suggest that any presently available adequate substitute for cortisone, for example, hydrocortisone or large doses of adrenocortical extract, would be appreciably superior to cortisone in the management of problems of this sort.

RHEUMATOID SPONDYLITIS

To the Editor:—*A patient with spondylitis anklopoietica (Marie-Strümpell disease) also has sinusitis, and hemolytic streptococci and staphylococci have been cultured from the sinus lesions. Would a trial of autogenous vaccine be in order? Please discuss the etiology of this disease.*

M.D., Florida.

Answer.—No unanimity of opinion prevails about the use of vaccines in the treatment of articular diseases. Most rheumatologists no longer use either autogenous or stock vaccines, because the results have not been encouraging on critical evaluation; however, some physicians do still use vaccine therapy, and a trial of either an autogenous or stock vaccine would not be contraindicated in the case described. Before treatment with a vaccine is considered, specific treatment of the infection of the sinuses, including use of appropriate antibiotics and establishment of adequate drainage from the sinuses, is indicated.

Rheumatoid spondylitis (a term proposed by the American Rheumatism Association in preference to "Marie-Strümpell's arthritis") is an inflammatory, probably nonspecific disease affecting principally the sacroiliac joints and diarthrodial joints ("facets") of the spinal column. As in other rheumatoid diseases, the inflammatory process also may affect the periarticular, fibrous, and other mesenchymal tissues of the body. The etiology of rheumatoid spondylitis remains unknown. Comprehensive studies have indicated that many of the previously suggested concepts of its cause are not tenable at present. An ill-considered notion that rheumatoid spondylitis is due to hyperparathyroidism was apparently based on the prominence of calcification of vertebral ligaments with an associated osteoporosis of the vertebral bodies. This theory was at its zenith about 20 years ago but is now discarded. Another idea, also discarded, was that rheumatoid spondylitis is due to gonorrheal infection. This was probably proposed because of the tendency for both diseases to occur in young adult males. It also has been thought that rheumatoid spondylitis might be the result of focal infection, tuberculosis, or other infection of the sacroiliac joints or congenital anomalies of the lumbosacral segments of the spinal column, but these remain unproved and unlikely explanations.

Although injuries of varying extent to the back are apparently a common experience of both men and women, trauma cannot usually be related to the onset of rheumatoid spondylitis. Studies by Shands and Oates at Duke University and by Golding in England as well as by others interested in rheumatoid spondylitis have supported this observation. The onset of rheumatoid spondylitis could be related to trauma in only 7% of more than 1,000 cases studied at the Mayo Clinic by Polley. Most European rheumatologists are of the opinion that rheumatoid spondylitis is unrelated to rheumatoid arthritis of peripheral joints, but the consensus among most American rheumatologists is that these diseases are closely related to each other. Twenty-five to 50% of patients with rheumatoid spondylitis have associated arthritis of peripheral joints that is indistinguishable both clinically and pathologically from rheumatoid arthritis of peripheral joints seen in patients without rheumatoid spondylitis. Although the cause of rheumatoid arthritis also remains to be established, the prevalent opinion about the cause of rheumatoid spondylitis is summarized in the statement that "presumably, but not certainly, the cause of rheumatoid spondylitis is the same as that of peripheral rheumatoid arthritis" (Hench, P. S.; Slocumb, C. H., and Polley, H. F.: *M. Clin. North America* 31:879, 1947).

COMPETITIVE ATHLETICS FOR HIGH SCHOOL STUDENTS

To the Editor:—*Do you have information regarding the danger of the occurrence of cardiac hypertrophy, with permanent heart damage, owing to the strenuous physical exertion of competitive swimming at junior high school and high school levels?* *Stephen S. Ellis, M.D., Coffeyville, Kan.*

Answer.—Few controlled studies are available on the effect of strenuous physical exertion on the heart of normal youths of junior high school and high school ages. There is even less dependable information on the effects of swimming. No report of death from competitive swimming was found in a review of the literature from 1945 to the present. Best and Taylor (The Physiological Basis of Medical Practice, ed. 4, Baltimore, Williams & Wilkins Company, 1945) state, "It is now agreed that cardiac enlargements are the result of pre-existing disease and the normal heart cannot be dilated beyond its physiological limit, nor will a bout of strenuous exercise 'strain' the healthy heart muscle or cause it to fail. . . ." In a 1945 report of the Committee on the Cardiovascular Study of Athletes, Wolffe and Mueller state, "Unquestionably it is injudicious to allow on a school team students with a limited cardiac reserve shown, for instance, by a history of rheumatic fever and evidence of damage to some important part of the heart. . . ." (The Heart of the Athlete, Report of the Committee on the Cardiovascular Study of Athletes, Philadelphia, 1945). Smith (*Proc. Staff Meet., Mayo Clin.* **10**:122, 1935) states, "The point I want to emphasize is that strenuous physical exercise and hard manual labor do not cause, or predispose to, heart disease; that such activities do not cause abnormal cardiac hypertrophy and that the athletes do not develop early disability and die because of exercise they indulged in while in school." Johnson, Brouha, and Darling stated in *Revue canadienne de biologie*, June, 1942, "We have had many years' experience in working normal healthy young men to exhaustion on the treadmill, rowing machine or bicycle-ergometer and have never observed any undesirable sequelae." In the Report of the Joint Committee on Athletic Competition for Children of Elementary and Junior High School Age, published by the American Association for Health, Physical Education and Recreation, in 1952 (Washington, D. C.), a questionnaire study of physicians' reactions to athletics for children is tabulated in terms of a number of health factors. Of the 220 physicians expressing an opinion, only two (0.9%) considered competitive swimming not advisable for children 12 to 15 years of age. This suggests that swimming is not considered a hazardous competitive sport by the physicians queried. It would appear from the evidence available that normal children in the 7th to 12th grades can safely compete in swimming, provided they are safeguarded by medical examinations that give reasonable assurance of no abnormal heart condition and they are supervised by a competent coaching staff.

HOT FLASHES LONG AFTER THE MENOPAUSE

To the Editor:—*Hot flashes sometimes are complained of 5, 10, or even 15 years after the cessation of menstruation. What is the explanation, and is there any special treatment beyond the sparing use of estrogens?*

D. A. MacGregor, M.D., Wheeling, W. Va.

Answer.—The vasomotor symptoms of the menopause are due to the inevitable endocrine readjustment following the cessation of ovarian function. The query does not state whether this patient has been given estrogens, but there is no doubt that too persistent therapy of this sort, putting into the woman's circulation what nature is trying to get rid of, defers the inevitable readjustment. Estrogen therapy, if it has been used, should be discontinued, and the chief reliance should be on psychotherapy and simple sedatives.

PRIMARY TUBERCULOSIS

To the Editor:—*1. Is primary hilar tuberculosis considered infectious? Should a child with primary tuberculosis be admitted to a general pediatric ward? 2. What is the point in examining gastric juice in primary tuberculosis? If an acid-fast bacillus is found or if the injected guinea pig dies of tuberculosis, is this proof that the patient is infectious to others? 3. Two asymptomatic children are Mantoux positive. One shows no roentgenographic changes and the other a large mass of hilar nodes. Is there any difference in their infectivity to others? Is there any difference in their prognosis? 4. A child, aged 2 years, lives in an orphanage. His father has open tuberculosis. The child is symptomless and has no roentgenographic changes but had a Mantoux conversion three months ago. Should he stay at the orphanage or be admitted to a hospital? Another child, aged 6 years, had a Mantoux conversion nine months ago and has a large hilar flare without symptoms. Should he stay at the orphanage? 5. Is there good evidence that rest is beneficial in the treatment of primary tuberculosis, even if large hilar nodes are present? Provided children are not fatigued, is it not better to treat them as outpatients rather than admit them to a hospital, especially since they get no specific chemotherapy? 6. Frequently one hears that children with primary tuberculosis should have routine lumbar punctures to detect cases of meningitis early. May not this procedure cause meningitis by releasing the pressure on a tiny unsuspected subcortical tubercle so that the tension inside it causes it to rupture into the cerebrospinal fluid?*

S. Levin, M.D., Boston.

Answer.—As far as possible, the answers will be given categorically as the questions have been asked: 1. Primary hilar tuberculosis is not necessarily considered infectious. Open pulmonary lesions must also be present before bacilli can escape into the bronchial secretions. It is true that Ranke claimed that lymph nodes along the main bronchi may discharge bacilli into the bronchi by a "leakage" process, which he called "hilus catarrh." Leakage from the large nodes at the hilum would, however, be rare, and any such "leakage" would contain so few bacilli that they would probably never get past the lips to infect others, although they may be found in the gastric washings. Children with primary tuberculosis may be admitted to pediatric wards, but quarantine techniques should be carried out in handling them, because it cannot always be foretold when the patient will become sputum positive and infect his highly susceptible associates. 2. There is much to be gained in gastric lavage in primary tuberculosis. It is true that many times few bacilli are present, and they may be found only on culture and guinea pig inoculation, but it is a worth while procedure. Before the advent of antibiotic therapy and chemotherapy, Paulson found that in the average primary tuberculous infection tests remained positive for about three years. Now the time is much shorter, but the presence of tubercle bacilli in the gastric secretions is evidence of continuing activity of the disease, although it may appear healed. The finding of bacilli in gastric secretions does not always mean the child will infect others. Unless bacilli are found in the sputum or throat swabs, the possibility of infecting others is extremely unlikely. 3. While there are exceptions to all rules, there would generally be expected to be a decided difference in the infectivity of the two children. The one without roentgenographic changes would most likely have negative sputum and gastric secretions, while the other, during the active phase of the disease, would have positive gastric secretion and may have positive sputum or throat swabs and thus would be infectious. It may happen rarely that an open lesion will exist behind the heart or in the "invisible" areas of roentgenograms of the lungs, in which event the secretions will be positive. 4. The first child may remain in the orphanage so long as he does not show signs of clinical disease, roentgenographic evidence of clinical disease, and, especially, positive mouth or gastric secretions. He should be examined monthly, for several months, until presence of the infection is proved or disproved, and action should be governed accordingly. The second child should be removed if his mouth secretions are positive and should be given drug therapy, which should render his secretions negative and safe in a few months, after which he may be returned to the orphanage. 5. There is no good evidence that rest is beneficial in primary tuberculosis. Rest as applied to active adult disease is not necessary. During any active or febrile phase of primary diseases, as much rest is recommended as can be had, but when the patient becomes symptom-free rest has been found unnecessary. This latter fact was established by Myers, in Minneapolis, when he closed the Lymanhurst Institution. The child should not, however, become fatigued, and good hygienic measures should be followed. It is better to treat such a child as an outpatient. 6. Lumbar puncture is liable to do more harm than good, as the questioner suggests. Besides, the chances of finding positive cases so early in meningitis are so remote it would be an utter waste of time.

CARE OF THE HAIR

To the Editor:—*How often should one's hair be shampooed? Of what value are detergents? I hear so much about different brands, yet I am hopelessly mired in ignorance. Is there any harm in putting water on the hair when grooming it?*

M.D., California.

Answer.—Washing the hair per se will not result in hair damage but if strong cleansing agents are consistently used, the hair and scalp may become excessively dry. Years ago, cleansing agents were often more alkaline than they are today, and inferior shampooing results were not rare. There are few persons who find it necessary to wash the hair more than twice a week. The average person in a city may require shampoos once a week. Wetting the hair for grooming purposes is not harmful. The type of detergent used in a particular shampoo is a trade secret, unless the manufacturer wishes to disclose it. Some shampoos contain both a soap and a synthetic detergent product. The most satisfactory criterion for determining shampoo action is to experiment with several reputable brands until one is found that suits the individual needs. This experimentation will not result in serious hair damage. The most that will occur is temporary excessive dryness and such cosmetic disadvantages as inferior manageability and hair gloss. In general, synthetic detergents are efficient cleansers, and some would not be suitable for any but extremely oily hair; however, by the addition of certain chemicals, cleansing ability can be decreased, and a product can be produced that is satisfactory for dry and average hair. When excessive dryness of the hair persists despite a change in shampoos, other causes should be investigated. Over-processing during permanent waving is a common cause of brittleness and dryness of hair. The possibility of organic causes also should be ruled out.

NEUROFIBROMATOSIS

To the Editor.—*Today I saw a 29-year-old woman with what undoubtedly is neurofibromatosis. I biopsied a lesion several years ago. Her affliction started about 12 years ago, and she is covered with hundreds of these lesions. Her face is pitiful. It has been my impression that surgical removal of the lesion, which actually causes pain, is about the only treatment recommended. Would there be any merit in considering the use of an estrogenic hormone? Since corticotropin (ACTH) or cortisone has been tried in every other known affliction, have these preparations been used in this disease?*

M.D., Alabama.

Answer.—Neurofibromatosis (Recklinghausen's disease) starts before the age of 17 or 18 and usually makes its first appearance in early childhood, although it may reach its peak when the patient is in his twenties. Surgical removal of the painful lesions is the most satisfactory method of treatment. There is no reason to believe that corticotropin or cortisone would be of any value. Other hormones used in the past in the treatment of this disease have had no effect.

REPEATED ATTACKS OF ERYTHEMA NODOSUM

To the Editor:—*A married man, aged 38, has a history of vivax malaria, colitis of many years duration, and repeated attacks of erythema nodosum. At the age of 34, while at rest, he felt a hypesthesia involving the right face and arm, which subsided after an hour; at the time he had erythema nodosum. In 1952, after a healthy four years, he had a severe supraorbital headache, an unnatural feeling of extreme fatigue, and difficulty in walking properly and in writing. This gradually subsided in a day or two, with complete recovery. In December of the same year, again following strenuous work and sleeplessness, he had the same headache with extreme fatigue, but this time he noted a short-lasting diplopia involving the right rectus lateralis. Results of physical examination during and after the attack, blood cell counts, and serologic tests for syphilis have been negative. Roentgenograms of the skull are not contributory. I would appreciate your opinion on diagnosis and management in this case.* *M.D., Lebanon.*

Answer.—Erythema nodosum is a symptom complex, not a specific disease entity. It may be a manifestation of any of the following conditions: ingestion of such drugs as iodides, bromides, or sulfonamides, endocarditis, arthritis, recurrent septic sore throats, rheumatic fever, tuberculosis, leprosy, syphilis, malaria, trypanosomiasis, venereal lymphogranuloma, chancroid, acute exanthemas, Neisseria infections, typhus fever, Boeck's sarcoid, fungus infections, and, frequently, infection with intestinal parasites. The history of the patient in question, while lacking in many specific details, gives some highly suggestive points of approach, namely, youth, a history of vivax malaria, stubborn colitis, and repeated attacks of erythema nodosum, some early symptoms of a vascular or nervous nature, fleeting hypesthesia, impaired locomotion and ability to write, and short-lasting diplopia. All of these episodes followed extreme physical fatigue and sleeplessness. A chronic cerebral malarial infection would produce any of the above symptoms, individually or grouped. In this type, the blood is usually negative for malarial parasites. A spinal fluid examination is indicated, and would show increased pressure, up to 400 lymphocytes per cubic centimeter, abnormally high albumin and globulin levels, and also, sometimes, pigments from malarial parasites. Meningism may be the cause of diplopia. The colitis could be a manifestation of an abdominal type of malaria. Undulant fever should be eliminated by means of a Brucellergen (a suspensoid of protein nucleate derived from Brucella organisms) test. Roentgenographic examination for internal Boeck's sarcoid and a more complete history, including information on episodes of fever, travels, and diseases endemic in the environment of this person, would help. No opinion about management has any value until a definite diagnosis has been established.

OCCUPATIONAL THERAPY IN EARLY RHEUMATOID ARTHRITIS

To the Editor:—*In an early stage of rheumatoid arthritis when the joints of fingers, hands, and wrists are becoming swollen, painful, and stiff, is playing the piano a helpful exercise? Can it be recommended as a pleasant substitute for the usual exercises, which are exercises and nothing more?* *M.D., Texas.*

Answer.—Carefully planned occupational therapy may not be entirely satisfactory as a substitute for exercises in rheumatoid arthritis, but occupational therapy has the great advantage of minimizing the monotony and boredom that may accompany performance of calisthenic-like exercises. Physicians who plan occupational therapy for patients with rheumatoid arthritis should keep in mind certain objectives: the activity should consist of work that is interesting, the work chosen should entail articular and muscular movements calculated to maintain and improve action of affected joints, and the work involved should not cause excessive fatigue. Occupational therapy that is properly planned may serve an important function in ridding patients of feelings of helplessness and dependency. Playing the piano may serve well as occupational therapy for rheumatoid arthritis involving fingers, hands, and wrists. The duration of practice should be supervised and should depend upon the character of the disease. If the process is active and swelling is pronounced, 10 or 15 minutes should suffice. If the disease is relatively inactive, the amount of time devoted to practice can be prolonged.

INTRAUTERINE FETAL DEATH

To the Editor:—*A 22-year-old woman is married to a third cousin. Her mother and father-in-law are first cousins. Her blood is type B, Rh-negative, and her husband's blood is type AB Rh-negative. About one and one-half years ago, she gave birth to a 3¾ lb. (1,701 gm.) boy one week after expected confinement. The infant lived only a few hours. The placenta was said to be normal. Autopsy revealed no apparent cause of death. In December, 1952, after a second uneventful pregnancy, she noted a cessation of fetal movements at the onset of labor. A dead, macerated female fetus, weighing less than 4 lb. (1,814 gm.) was delivered about eight hours later. Three infarcts were noted in the placenta. Autopsy again revealed no apparent cause of death. The patient's blood pressure ranged between 120/80 and 142/90 throughout the pregnancy. At no time was albuminuria, pyuria, or glycosuria noted. The results of the Mazzini test were negative. The patient's weight gain was normal. What would cause these fetal deaths and the infarcts noted in the second pregnancy? Should this woman attempt to conceive again, and, if so, should a cesarean section be done about two weeks before expected term in the hope of getting a viable child?* *M.D., New York.*

Answer.—Little information is available concerning the factors that predispose to intrauterine fetal death, with or without associated infarction of the placenta, in women who do not have chronic hypertensive vascular disease. A complete study of the patient, which should include the usual kidney function tests, will rule out the latter condition. It may be well to check thyroid function by means of a blood protein-iodine determination as well as a basal metabolism test. The distant relationship of the parents is of no importance in causing the fetal deaths. The mother should be encouraged to conceive again. She should be encouraged to take a high protein diet but to restrict her weight gain to no more than 8 to 10 kg. If she has hypometabolism, she should receive thyroid. It is preferable to await a natural delivery unless toxemia should begin to develop. The small size of the fetuses may be an indication of poor nutrition because of an inadequate uteroplacental blood supply. In chronic hypertensive vascular disease the lesion is in the placental site, which leads to changes in the placenta and a decreased circulation to the fetus.

MENTAL DEPRESSION DURING MENSTRUATION

To the Editor:—*Please discuss the management of a 37-year-old woman who is greatly depressed one to two days prior to, during, and seven days following menstruation. There is no appreciable change in the menstrual cycle, and no organic disease can be found.*

George E. Quinn, M.D., Farmington, N. H.

Answer.—This patient obviously needs sympathetic psychiatric study to find the cause of her depression. There is a tendency to relate these things to the menstrual cycle when the real trouble is psychiatric. Naturally, just before the menstrual period the hormone blood levels rapidly drop, and a certain degree of letdown is understandable, but it happens in all women who menstruate and does not cause undue depression. This patient should not be treated with hormones, because, although such therapy may temporarily give slight improvement, it would not solve her basic problem and would eventually fail to give relief.

MULTIPLE POSITIVE REACTIONS TO ALLERGIC SKIN TESTS

To the Editor:—*A patient, aged 43, had no allergic manifestations until four months ago, when he received three daily injections of penicillin. Later he began to take a standard multivitamin and multimineral tablet. The list of positive reactions found by a competent allergist is enclosed. I have never seen a report with so many positive results. I am suspicious of the penicillin or the vitamin and mineral tablets. With all these allergies, the patient is kept well under control by the use of the antihistamine preparation methapyrilene hydrochloride (Histadyl). How should I proceed in this case?* M.D., *New Jersey.*

Answer.—If the urticaria began several days after penicillin administration it is probably an example of the common form of the "serum sickness" type of reaction to this antibiotic. This type of urticaria or angioneurotic edema resulting from a penicillin reaction may last for hours or months or even longer than a year. Ultimately the syndrome disappears. The diagnosis is made from the clinical history and the exclusion of other possible causes of urticaria. The result of a skin test with penicillin is almost always negative in this type of allergy. Furthermore, in the majority of all types of urticaria, the skin tests are negative. Certainly the majority of positive skin tests as reported in the attached list have no bearing on the patient's complaints. There are several possible explanations for the large number of reactions. One of the most likely is the patient's skin irritability, which often occurs in urticaria. The allergy tests reported to the inquirer constitute a classical example of the many types of misapplication and misinterpretation of the skin test in allergy. Provided the timing of the onset is compatible with a history of penicillin reaction, the best advice to the patient is to disregard the syndrome, except for obtaining symptomatic relief.

FUNGUS INFECTION OF NAILS

To the Editor:—*A friend has a fungus infection of all the nails on one hand. He has consulted dermatologists, none of whom had any satisfactory treatment. The nail bed is being replaced by irregular, white, raised, dry areas, which become piled up unless they are scraped down. Has plastic surgery been tried? If so, please describe this method.* M.D., *Arkansas.*

Answer.—It would be desirable to isolate and identify the causative organism in this case. Such identification might give a better idea of the prognosis, because new fungicides and new keratolytic vehicles are constantly being introduced for which claims for specificity are made. All such drugs should be tried before resorting to surgical avulsion, because the results from surgery are too often unsatisfactory. If the nails are removed by surgery, the nail bed and matrix must be treated thoroughly and continuously with fungicides.

SOFTENED WATER

To the Editor:—*Is there any danger in using water softened by ordinary commercial softeners for drinking or cooking purposes? Is there any benefit? Does such water have any effect on nutritive value of cooked foods?*

Arthur W. Anderson, M.D., Lexington, Neb.

Answer.—Any proper water softening is without significant physiological import. The advantages of softened water chiefly are economic, relating to such matters as laundering, hair washing, conservation of detergents, cleanliness of plumbing fixtures, and taste and appearance of food. Some hard waters modify the appearance of tea and the flavor of coffee. It is true that well-softened waters employed in cooking extract a higher percentage of the minerals of vegetables and possibly of the vitamins, but this is not characteristic of ordinary chemically softened waters. In general, it may not be claimed that softened waters introduce physiological detriment, and the advantages far outweigh any usual objections.

CHOLINE AND METHYLENE BLUE

To the Editor:—*Is the use of choline 5 grains (0.32 gm.), in 1 oz. (30 cc.) of an alkaline eye wash solution contraindicated? Is the use of methylene blue, in a proportion of 1/150 grain (0.4 mg.) per 8 oz. (250 cc.) of alkaline eye wash solution contraindicated when choline is included in the solution? Does choline have the power of inducing penetration in the deep structures of the eye coats if methylene blue is included in the proportions mentioned, and is there any possibility of permanent stain in these structures? Will methylene blue in such proportions have antiseptic or germicidal properties of value?*

Vincent Boccella, M.D., Glenside, Pa.

Answer.—Choline, a viscid, strongly alkaline liquid, is commercially available, but the salts are usually used, the most popular forms being choline chloride and the more stable choline dihydrogen citrate. The bicarbonate and borate salts are also obtainable. In 1% solution, choline bicarbonate is slightly alkaline and choline dihydrogen tartrate slightly acid. Either could be used in the eye wash, the choice depending on the final pH desired. Methylene blue is easily salted out of solution and, hence, is considered unsuitable for coloring solutions of salts. The suggestion that choline can induce penetration in the deep structures of the eye coats, originally proposed by Dmitry, has not received experimental support. In any case, no permanent stain can result from the use of methylene blue, as the compound is rapidly reduced in the tissues to the colorless form. Although methylene blue is antiseptic for pure cultures in 1:150,000 dilution, the proposed eye wash would have three times this dilution. Methylene blue is a slow-acting, weak germicide, and, in the colorless form, it is inert.

GIANT CELL TUMOR OF FEMUR

To the Editor:—*Please advise me concerning a benign giant cell tumor of the distal end of the femur. What are the advantages of amputation and the possibility of eventual metastasis if amputation is done, even though the tumor is considered benign at present?*

Louise M. Puglise, M.D., Brooklyn.

Answer.—The treatment of benign giant cell tumor of the distal end of the femur may be carried out in one of two ways. The area may be exposed to doses of roentgen rays given through several portals with protection of the bone by crutches or splint to prevent pathological fracture, or the lesion may be removed by thorough curettage and the use of an escharotic, such as zinc chloride solution, followed by packing with bone chips and primary closure of the wound. In the surgical treatment of giant cell tumor, it is essential that the complete removal be done at the first operation and that primary wound healing be obtained. Amputation should be confined to cases in which there has been evidence of a transformation to malignant giant cell tumor or cases in which wound infection and fungation precludes satisfactory management by any other method. Such a surgical complication nowadays is seldom encountered. The possibility of metastasis as a late complication after amputation in a tumor that is histologically benign is exceedingly remote, and the life expectation of a person who has had an amputation while the lesion is histologically benign should not be adversely affected.

TESTS FOR LIVER DAMAGE

To the Editor:—*How long must complete extrahepatic obstruction of a normal liver be present to produce enough hepatocellular changes to be manifested by abnormal cephalin-cholesterol flocculation and thymol turbidity?* M.D., *Tennessee.*

Answer.—Abnormal cephalin-cholesterol flocculation and abnormal results in other tests for hepatocellular damage usually become apparent within a few weeks after complete extrahepatic obstruction of the biliary tract. Therefore, results of these tests will usually be normal during the first week or two. This is of value in differential diagnosis between an obstruction and acute hepatitis.

USE OF ANTICHOLINGERIC DRUGS IN PEPTIC ULCER

To the Editor:—*A recent news item described a substance designated BA-5473, which was reportedly effective in the management of peptic ulcers. My patient has a large ulcer and is interested in trying this drug. Kindly inform me whether the news item was correct and where the drug is available.* *Millard Pasthuma, M.D., Cadillac, Mich.*

Answer.—Shortly after the demonstration by Dragstedt and his associates that gastric vagotomy had a beneficial effect on the healing of duodenal ulcers, attempts were made to produce medical vagotomy by means of drugs that would depress or paralyze the vagus nerve endings in the stomach. Several such anticholingeric drugs are now available, and they exert a depressant action on the nervous mechanism of gastric secretion without producing side-effects that are prohibitive. Some of the newer drugs depress gastric secretion even after the vagus nerves to the stomach have been divided and so may be said to have a true antisecretory action. At present, until more extensive clinical trial has been made, it is wise to use these preparations as adjuvants to the standard type of medical management employing alkalies and frequent feeding. BA-5473, or Antrenyl (oxyphenonium bromide), manufactured by Ciba Pharmaceutical Products, Inc., of Summit, N. J., is one of these preparations.

MULTIPLE OSTEOMAS OF SKULL

To the Editor:—*I should like information about treatment of multiple osteomas of the skull in a 25-year-old woman. They have been present for at least 10 years, are slowly progressing in size, and so far have produced no neurological changes. The largest one is in the center of the forehead and causes a noticeable deformity, which is becoming a psychological problem. The roentgenographic appearance shows dense bony tumors that extend inside the cranial vault. Would it be possible to improve the patient's appearance by making an incision from above the hairline and trimming off the osteoma flush with the normal plane of the forehead?* *M.D., Washington.*

Answer.—From the description, this is an unusual case. There is not sufficient detailed information given to make a diagnosis. Multiple osteomas are seldom seen. If the tumors in this case extend intracranially they would not appear to be ordinary osteomas. They may possibly be meningiomas. In making a diagnosis in this case, roentgenograms should be of considerable assistance and ought to be interpreted by a competent roentgenologist. If the tumor extends intracranially, it probably should be removed along with the inner table of the skull with a tantellum plate used for replacement. If the tumor extends into the region of the longitudinal sinus, this would have to be taken into consideration.

GLASS IN INTESTINAL TRACT

To the Editor:—*A patient swallowed some glass that was in the bottom of a soft drink bottle in August, 1952. 1. How long can the glass remain in the intestinal tract without penetrating the wall and without being expelled in the feces? 2. Can the glass penetrate the wall of the intestinal tract without producing noticeable peritonitis? 3. If a small portion of the glass penetrates the wall of the intestinal tract, what is the possibility of it subsequently traveling to a remote vital organ and causing damage there?*

M.D., Georgia.

Answer.—1. Glass, unless it becomes attached to the bowel wall, passes normally through the digestive tract surrounded by feces. 2. Glass penetrating through the intestinal wall produces local or generalized peritonitis. 3. A spicule of glass may travel like a needle and penetrate a distant organ in the abdomen. Some pieces of glass are radio-opaque and may be seen roentgenographically.

POLYPS IN THE DUODENUM

To the Editor:—*A roentgenologist has observed a polyp in the first portion of the duodenum of a woman who has no gastrointestinal symptoms. Do such polyps ever become malignant? What is the consensus regarding their removal?*

L. R. Evans, M.D., Laramie, Wyo.

Answer.—Polyps in the first portion of the duodenum are relatively rare. If they are sessile polyps and are on a long pedicle, they may cause an obstruction by migrating in through the pyloric canal. Their relation to malignancy has been questioned by many workers; however, they should be removed, because of the possibility of the occurrence of obstructive manifestations and interference with the normal motility of the duodenum and because they have a great tendency to become ulcerated. Profuse bleeding may ensue. Air bubbles in the duodenal bulb often simulate polyps in roentgenograms. Present day fluoroscopic compression techniques disperse this air so that such errors in diagnosis now occur less frequently.

TUBERCULOSIS IN YOUNG CHILD

To the Editor:—*In October, 1950, a 17-month-old child was found to have pulmonary miliary tuberculosis. He was given thiazolsulfone (Promizole) and 1 gm. of streptomycin daily for five months. Streptomycin therapy was discontinued, and thiazolsulfone alone has been given up to the present. The chest roentgenogram has remained stable since June, 1951; the sedimentation rate, the white blood cell count, and the differential count have been normal since January, 1952. The child has had no fever during this period and is eating well and gaining weight. Can you advise from these meager details whether thiazolsulfone therapy should be discontinued? Should withdrawal be abrupt or gradual?*

B. F. Grotts, M.D., Michigan City, Ind.

Answer.—The principal danger facing the patient with arrested miliary tuberculosis is tuberculous meningitis. When meningitis occurs, it usually develops within the first year following arrest of the disease by the use of specific drugs. It appears probable that, since two years have elapsed in the case described, adequate treatment has been given.

SMALLPOX VACCINATION OF INFANT

To the Editor:—*A 3-month-old healthy male infant has had three smallpox vaccinations with vaccine of a standard make and has never shown any reaction. The mother was vaccinated when she was a baby; she is now 23 years old. I have never seen such a case. When should smallpox vaccination be attempted again?*

Eugene M. Kistler, M.D., Allentown, Pa.

Answer.—Inherited immunity to smallpox often persists in an infant for six months or longer, provided the mother has had a successful vaccination. This probably is the reason for the failure to obtain a successful vaccination in the first three attempts. An attempt should be made after three more months have elapsed.

ICHTHYOSIS

To the Editor:—*A girl, 11 years old, has ichthyosis and, in addition, teeth that are poorly formed, yellow, and pitted. She has a low basal metabolism and has been taking 1 grain (0.06 gm.) of thyroid three times a day along with Maltine with cod liver oil and creosote. She eats well and drinks adequate amounts of milk. Have you any suggestions?*

Watson B. Morris, M.D., Springfield, N. J.

Answer.—Ichthyosis is a congenital abnormality. A specific cause has not been established. Mild cases sometimes clear up spontaneously at puberty, and in some cases the administration of vitamin A seems to be effective. A soft ointment containing 2% salicylic acid is usually helpful. The changes in the teeth may be independent of the cutaneous disorder.

AIR EMBOLISM FOLLOWING ARTIFICIAL PNEUMOTHORAX

To the Editor:—*In* The Journal, *May 16, 1953, page 293, is a discussion of air embolism following artificial pneumothorax, in which it is said that nothing can be done for this type of air embolism except to hope that it does not reach a vital center. Cases are on record in which the immediate change of the patient's position to the left lateral recumbent or the Trendelenburg position, which permits trapping of the air bubble above the blood in the right ventricle, has enabled the observer to aspirate air directly from the right ventricle. Such a procedure was reported by Stallworth, Martin, and Postlethwait in* The Journal (**143:***1250 [Aug. 5] 1950).*

William B. Bean, M.D.
State University of Iowa, Iowa City.

To the Editor:—*The answer to the query on air embolism following artificial pneumothorax in* The Journal *May 16, page 293, is misleading, probably because the query is misunderstood. The query relates an incident of air embolism to the right ventricle following refill of an extrapleural pneumothorax. In the answer air embolism occurring in intrapleural pneumothorax is discussed. Air embolism from extrapleural pneumothorax usually does not result from a bronchovenous fistula, as occurs in the case of intrapleural pneumothorax. It is probable that a systemic vein was lacerated in this case so that air already present in the extrapleural pneumothorax space was able to enter the venous return to the heart and obstruct blood flow to the lungs from the right ventricle. Death was due, therefore, to forward cardiac failure and peripheral ischemia rather than to air embolism to the coronary arteries or centers of respiration in the brain. The latter could occur only if there was a congenital opening between the two sides of the heart so that air entering the right chambers could cross into the left chambers and then proceed to the peripheral circulation. The treatment the California doctor used was correct; he turned the patient on the left side hoping that an air trap in the outflow tract of the right ventricle would be relieved, since in the left decubitus position the outflow tract is inferior to the rest of the right ventricle and the air would rise out of the outflow tract. The principle involved has been studied by Dr. Thomas Durant and his associates* (Am. Heart J. **33:***269, 1947;* Pennsylvania M. J. **56:***279, 1953). It is possible to prevent death in such cases, if the amount of air entering the right ventricle is not excessive.*

I take exception to the statement, "The accident should never happen if the technique is good and the cases are properly selected." Such accidents may happen regardless of how careful the operator is, because it is not possible for him to have his eye at the point of the needle so that he can see where it is going and avoid lacerating blood vessels.

William Weiss, M.D.
Philadelphia General Hospital, Philadelphia 4.

To the Editor:—*In his reply to the query on air embolism in* The Journal *for May 16, 1953, page 293, I think your authority has confused arterial and venous air embolism. The inquirer says that air was introduced into an extrapleural pneumothorax and at autopsy the right ventricle was full of air. This phenomenon was therefore due to air entering a systemic vein and reaching the right side of the heart. When the needle forms a communication between a bronchus and a pulmonary vein, air reaches the left ventricle and causes symptoms by entering the coronary arteries (death) or cerebral arteries (such as hemiplegia or visual defects). It is possible for air from the right side of the heart to reach the brain if there is a patent interauricular septum or if it passes up the internal jugular vein or traverses the paravertebral plexus of veins. Diagrams showing the routes taken by air emboli can be found in "Emergencies in Medical Practice," edited by C. Allan Birch (ed. 3, E. & S. Livingstone, Edinburgh, 1952).*

It may be added that to turn the patient on the left side is good treatment in all cases. When air is in the right ventricle, it is less likely to obstruct the outflow tract if the patient is lying on the left side. When air is in the left ventricle, it is less likely to enter a coronary artery when the patient is in this position because the part of the aorta that is uppermost does not have a coronary orifice.

C. Allan Birch, M.D.

TREPONEMAL IMMOBILIZATION TEST

To the Editor:—*To the information on the treponemal immobilization test in* The Journal *March 14, 1953, I would like to add that the Division of Venereal Disease Control, Province of Ontario, commenced use of the Treponema pallidum immobilization test toward the end of 1951, as a service to physicians in this province. The use of the test originally was restricted largely to cases in which physicians had difficulty in interpreting the results of the standard serologic tests. Priority was given to specimens from prenatal, premarital, and preemployment subjects. The physicians of the province cooperated to such an extent that in July, 1952, the department of health of Ontario was in a position to extend this service to the remaining nine provinces of Canada as well as to the armed forces. The average number of specimens received each week rarely exceeds 100, which is the maximum capacity of the TPI unit in the central public health laboratories in Toronto. The director of the Division of Venereal Disease Control feels that the test is one more aid in resolving the difficult problem of differential diagnosis in latent syphilis. For physical and other reasons, the services of the Treponema pallidum immobilization test are provided only for the physicians of Canada, through the divisions of venereal disease control for each province.*

George W. Miller, M.D.
Assistant Director
Division of Venereal Disease Control
Department of Health
Province of Ontario, Toronto, Canada.

CONGENITAL HYDROCELE

To the Editor:—*In the Query and Minor Note on "Congenital Hydrocele" in* The Journal *Feb. 21, 1953 (page 694), it is stated, "simply closing the inguinal area off alone and leaving the distal end in situ would most likely be followed by a recurrence of hydrocele fluid accumulation." For some unknown reason, this is not true. I have treated many patients with congenital hydrocele by transecting the sac along the cord and closing the inguinal area in one way or another to prevent congenital hernia. Occasionally, I have split the distal end of the hydrocele sac lengthwise for a short distance down the cord; however, I have never removed or everted it. To my knowledge, the hydrocele has not recurred, and some of my patients have been followed closely for more than 10 years. Undoubtedly, the incidence of traumatic injury to the vas deferens is related directly to the extent of surgery performed within the scrotum. In young children, particularly, the vas deferens is very delicate in the dependent portion of the scrotum, and the chance of its occlusion by traumatic injury is probably greater than the chance of a recurrence of the hydrocele fluid if the distal end of the sac is left in situ.*

TUBAL LIGATION IN RH-NEGATIVE MOTHER

To the Editor:—*The answer to the query in* The Journal *May 16, 1953 (page 295), about tubal ligation in the Rh-negative mother who has had an erythroblastotic infant should be amplified. It is important that the father's Rh genotype be determined, because, if he is* Rh_0 *heterozygous, half the progeny will be Rh negative. There are more* Rh_0 *heterozygotes than homozygotes. The statement that tubal ligation is an entirely final procedure is, of course, true, but the family may be offered a ray of hope in the determination of the father's Rh genotype.*

SPLANCHNICECTOMY FOR ESSENTIAL HYPERTENSION

RESULTS IN 1,266 CASES

Reginald H. Smithwick, M.D.

and

Jesse E. Thompson, M.D., Boston

Hypertensive cardiovascular disease remains one of the foremost problems facing medicine today. It has been estimated that one-fourth of the adult population of this country has high blood pressure[1] and that the complications of this condition account for more deaths annually than does cancer. Hypertension is of particular importance because it is responsible for many deaths and much premature disability in young and middle-aged persons. It is highly desirable, therefore, to lower the mortality for such a disease.

Many forms of therapy have been used in an effort to control hypertension. The principal ones may be classified under three headings: (1) diets low in sodium and fat, (2) drugs with a hypotensive or sedative effect, and (3) surgery. The form of surgical therapy that has been used most extensively is intervention on the sympathetic nervous system. There are many data in the literature concerning the short-term effects of various forms of therapy on blood pressure levels, the cardiovascular system, and symptoms. The important point, however, is the effect of a particular form of therapy on life expectancy, expressed as mortality and survival rate, regardless of its effect on blood pressure. On this point there is a paucity of data in the literature. Recent reports by one of us (R. H. S.) have emphasized this concept.[2] It is obvious that, to evaluate prognosis in a statistically significant fashion, one must follow large numbers of patients for long periods of time. For evaluation of surgical therapy, a comparable control series of patients treated otherwise, or untreated, must be available for comparison. The control patients must be studied and classified in exactly the same fashion as the surgical patients.

Since 1938, when thoracolumbar splanchnicectomy was first introduced, we have studied about 3,500 hypertensive patients. Some 2,400 of these patients have had splanchnicectomy performed, and the others have been treated medically. Of the surgical patients operated on prior to Dec. 31, 1947, 1,266 have been followed from 5 to 14 years. During the same period 467 of the patients who were studied but were not operated on have been followed from 5 to 11 years. These patients were offered surgery, but for various reasons they declined. Since data from the literature were not wholly satisfactory for comparison with our surgical series, these 467 patients served as a control series. The purpose of this article is to report the effect of thoracolumbar splanchnicectomy on the mortality and survival rates of these 1,266 patients and to compare such data with those of the 467 medically treated control patients.

There are certain characteristics of our group of patients that should be clearly pointed out. We are aware of the fact that many patients with hypertension appear to tolerate it quite well and live long, useful lives without any treatment whatsoever. On the other hand, the patients who have been referred to us had unusually severe forms of the disorder, they had not improved with current forms of therapy, or their status indicated an extremely poor prognosis. All of the patients reported on, both surgical and medical, had persistent, not intermittent, hypertension, i. e., the blood pressure when the patient was in a horizontal position was 140/90 mm. Hg or more, both when he was ambulatory and after two days of bed rest in the hospital. They had, therefore, advanced through the earlier stages of the natural history of hypertension, namely, hyperreactivity of the blood pressure without hypertension and intermittent hypertension. The vast majority when first seen had evident vascular disease, manifested either in the eyes, heart, kidneys, or brain. They were, therefore, already in the stage in which

---

Mr. John Alman of Boston University made the statistical analyses for this study.

cardiovascular complications of hypertension had begun to occur. That our patients are representative of the severer forms of hypertensive disease is also evident from the survival curves of these patients when compared with a survival curve of the normal population of similar age and sex distribution (fig. 1).

Another point of importance is that all of the patients under consideration were first seen or operated on at a time when none of the more recently introduced hypotensive drugs or low sodium diets were available or in vogue. The surgical patients had no additional therapy prescribed on discharge from the hospital. Most of them have had no additional therapy, though in recent years some have had diets and drugs prescribed as necessary. The medical patients have, of course, had all available forms of current therapy. The results reported in this communication have not been influenced materially by "medical forms of sympathectomy" resulting from the use of adrenergic blocking drugs. It will be many years before it can be determined whether treatment by drugs of this general nature will be as effective as surgical treatment has been shown to be in significantly increasing the life expectancy of patients with the severer forms of hypertensive cardiovascular disease. It appears that in the severest cases a combination of all forms of treatment—diet, drugs, and surgery—gives the best results. In the future more patients will have dietary or drug therapy after surgery, but, as a rule, such additional therapy need not be as drastic as is the case when one depends on diet or drugs alone. It will, nevertheless, still be possible to compare surgical and medical cases, since the variable factor between otherwise comparable groups will be splanchnicectomy.

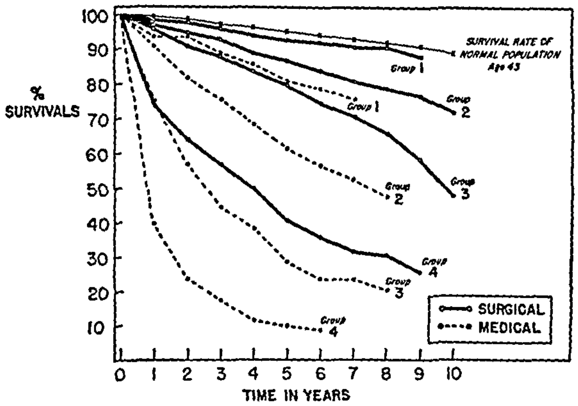

Fig. 1.—Survival curves for 1,266 surgically and 467 medically treated hypertensive patients. These curves have been constructed using the actuarial method. All patients were followed for at least five years and some for as long as 14 years, but the curves have not been carried beyond the 10 year mark in any case, because either the number of cases is too small to be significant or no further deaths occurred.

METHOD OF STUDY

It was first pointed out by Keith, Wagener, and Barker [3] that the prognosis for a hypertensive patient varies according to the status of his cardiovascular system when first examined. Unless patients with a similar degree of hypertension and of cardiovascular involvement are placed in comparable groups, no basis for comparison of results exists. This has been pointed out in a previous article,[2a] in which it was shown that mortality for different groups of unoperated patients reported in the literature varies tremendously, from 17 to 91%. We have, therefore, adopted a plan designed to control as many of the variable factors as possible, in an attempt to make the patient material in each group as comparable as possible. This plan is the best we have been able to devise to deal with the present number of cases. As the number of cases becomes larger, more variable factors can be controlled and groups can be defined more precisely.

After a careful study of the cardiovascular system as a whole, a numerical value is assigned to various factors having a bearing on prognosis. These are summarized in table 1. The numerical values for each factor present are totaled, and this gives the numerical grade for the patient. Two examples of how to determine the numerical grade are given at the bottom of table 1. If the numerical grade is less than 4 the patient will be in group 1 or 2. If the numerical grade is 4 or more the patient will be in group 3 or 4. The additional factors that determine the exact group of the patient are given in table 2. Thus the patients in group 1 have persistently elevated blood pressure, with minimal or no eyeground changes and no abnormalities in the cerebral, cardiac, or renal areas. Those in the other groups have increasing amounts of cardiovascular disease. A sedative test is done on all patients. Three grains (180 mg.) of amobarbital (Amytal) sodium are given by mouth at 7, 8, and again at 9:00 p.m. Readings of blood pressure are taken every hour from 7:00 p.m. to 7:00 a.m. The lowest reading of diastolic pressure during the sedative test is taken to be the response to sedation. To be regarded as satisfactory, the diastolic level during the sedative test should fall to 90 mm. Hg or less in patients with resting levels between 100 and 119 mm. Hg.

TABLE 1.—*Numerical Value of Various Factors That Influence Prognosis*

	Numerical Value of Each Factor
Cerebrovascular accident with or without minor residual	1
Abnormal electrocardiogram	
Enlarged heart	
or less than 60% in 2 hr.	
Age 50 or over	
Mild angina	
Cerebrovascular accident, with residual *	2
Frank congestive failure, moderate angina	
Phenolsulfonphthalein excretion, less than 20% in 15 min.	
Unsatisfactory response to sedation	
Phenolsulfonphthalein excretion, less than 15% in 15 min.	3
Nitrogen retention	4

* Cerebral deterioration or definite involvement of arm and/or leg.

Example 1

Abnormal electrocardiogram	1
Cerebrovascular accident without residual	1
Phenolsulfonphthalein excretion, 20% in 15 min.	1
Total	3 = Numerical grade of patient with hypertension

Example 2

Abnormal electrocardiogram	1
Enlarged heart	1
Phenolsulfonphthalein excretion, 10% in 15 min.	3
Total	5 = Numerical grade of patient with hypertension

3. Keith, N. M.; Wagener, H. P., and Barker, N. W.: Some Different Types of Essential Hypertension: Their Course and Prognosis, Am. J. M. Sc. **197**: 332-343 (March) 1939.

For patients with resting levels between 120 and 139 mm. Hg the response to sedation should be a fall to 100 mm. Hg or less. For those with resting levels of 140 mm. Hg or more, the diastolic level should fall to 110 mm. Hg or less. Otherwise, the response to sedation is regarded as unsatisfactory. Patients in both categories, surgical and medical, have been studied and classified in exactly the same fashion and can therefore be compared with respect to survival rates and mortality within the four groups.

TABLE 2.—*Classification of Hypertensive Patients*

Group	Numerical Grade	Other Factors
1	Less than 4	Eyegrounds grade 0 or 1 * No changes in cerebral, cardiac, or renal areas
2	Less than 4	Eyegrounds grade 0 or 1, with changes in cerebral, cardiac, and/or renal areas. Eyegrounds grade 2, 3, or 4 with or without changes in cerebral, cardiac, or renal areas *
3	4 or more	Resting diastolic level below 140 mm. Hg. Changes are present in cerebral, cardiac, and/or renal areas, but they do not include the following: Cerebrovascular accident, with marked residual Frank congestive failure Phenolsulfonphthalein excretion, below 15% in 15 minutes, associated with a poor response to sedation
4	4 or more	Resting diastolic blood pressure below 140 mm. Hg combined with one or more of the following: Cerebrovascular accident, with marked residual Frank congestive failure Phenolsulfonphthalein excretion, below 15% in 15 minutes, combined with a poor response to sedation Patients with a resting diastolic level of 140 mm. Hg or more

* Eyegrounds are graded according to the criteria of Keith, Wagener, and Barker.

RESULTS

Control Series.—The control series consists of 467 patients. This represents an 88% five year follow-up of the total patients originally studied. Sixty-one per cent were men and 39% women. The average age of this group was 45 years. These patients were offered surgery, but financial, personal, or reasons other than those related to the severity of the disease kept them from being operated on. In the early days of splanchnicectomy, before it was possible to exercise any degree of selection, all patients who were considered capable of surviving the operation were offered surgery. The mortality for the four groups in this series are given in table 3. Survival curves for these same patients are shown in figure 1. These survival curves have been constructed using the actuarial method, as described by Berkson and Gage.[4]

Surgical Series.—The surgical series consists of 1,266 patients. This represents a 90% five year follow-up of the total patients originally operated on. Forty-seven per cent were men and 53% women. The average age of this group was 42 years. Surgery consisted of thoracolumbar splanchnicectomy, carried out in two stages 10 days apart, through the beds of the 12th or the 11th and 12th ribs, using a retropleural, retroperitoneal, transdiaphragmatic approach.[2b] The sympathetic trunks were removed from the eight or ninth dorsal vertebra through the first or second lumbar vertebra inclusive, and the great splanchnic nerves were removed from the celiac ganglion to the midthoracic level. The adrenal glands, renal arteries, and kidneys were inspected, and renal biopsies were taken in all cases. The operative mortality has been low, ranging from 0% in group 1 to 11% in group 4, with an over-all operative mortality of 2.5%. The mortalities for the surgical series are given in table 3, where they are compared with those of the control series. The same data are presented in the form of survival curves in figure 1.

It is evident from a study of the data that the mortalities in all four surgical groups are significantly lower than in the corresponding medical groups. This is particularly true for groups 2 and 3, where the differences are quite striking and are highly significant. The difference is significant in group 1, but the number of cases in the medical group is still relatively small. More cases and a longer follow-up are needed before final evaluation of this group can be made. The difference between the group 4 cases is also very significant, but the eventual mortality is still very high. These differences are brought out in a striking fashion in figure 1, where the survival curves are compared. In the same figure is a survival curve of the normal population of similar age and sex distribution. The high mortality imposed by hypertensive cardiovascular disease is clearly shown and emphasizes the severity of the disease in the patients with whom we are dealing.

Although the important factor to be considered in evaluation of any form of treatment for hypertension is its influence on the mortality and the survival rate, the effect of treatment on the actual level of blood pressure is of considerable interest. In fact, it appears that blood pressure lowering in hypertension is desirable if it can be accomplished. It is fairly well established that in most cases the lowering of blood pressure in hypertensive patients is not harmful, providing such lowering is not excessive. The prognosis for patients whose blood pressure is lowered after splanchnicectomy is significantly better than for those whose blood pressure is not lowered by operation. Both of these groups, however, exhibit an improved prognosis when compared with the medical control series.[2b] It appears, therefore, that the outlook for hypertensive patients can be improved by splanchnicectomy even if the basal blood pressure levels are not significantly lowered postoperatively. Our data show that 45% of living operated patients have a significant lowering of basal blood pressure levels in the early years (1 to 5) after splanchnicectomy, and 55% have no change or show an increase in blood pressure.

TABLE 3.—*Mortality for Medically and Surgically Treated Hypertensive Patients**

	Medical Series		Surgical Series	
Group	No. of Cases	Mortality at 5 Yr.	No. of Cases	Mortality at 5 Yr.
1	62	19%	158	8%
2	200	38%	735	13%
3	108	71%	244	20%
4	97	90%	129	59%
Total	467	54%	1,266	19%

Statistical analysis of the comparative five year mortalities between the medical and surgical groups is as follows:

Group	Chi^2	p	Comment
1	4.92	0.03	Significant
2	60.6	< 0.001	Highly significant
3	83.2	< 0.001	Highly significant
4	24.6	< 0.001	Highly significant

* Yates correction used throughout.

[4] Berkson, J., and Gage, R. P.: Calculation of Survival Rates for Cancer, Proc. Staff Meet., Mayo Clin. 25: 270-286 (May 24) 1950.

To illustrate the effects of splanchnicectomy, the following cases are reported.

Case 1.—A 31-year-old man had an abnormal electrocardiogram, an enlarged heart, and congestive failure when examined prior to operation. His resting horizontal blood pressure was 160/122 mm. Hg. At examination 10 years after operation, his electrocardiogram was the same, his heart was normal in size, and there was no evidence of congestive failure. His eyegrounds showed minimal arteriovenous compression. The blood pressure (ambulatory) was 132/80 mm. Hg. This patient is an example of improvement in blood pressure and in cardiovascular status 10 years after splanchnicectomy (fig. 2).

Case 2.—A 48-year-old man had hemorrhages, exudates, and papilledema in his eyegrounds, an abnormal electrocardiogram, markedly enlarged heart, and severe congestive failure when examined prior to operation. His resting horizontal blood pressure was 204/104 mm. Hg. When examined seven and a half years postoperatively, his eyegrounds showed only arteriovenous compression and his heart was normal in all respects. His renal function showed slight evidence of impairment. His blood pressure (ambulatory) was 188/114 mm. Hg. This patient is an example of the marked improvement that may follow splanchnicectomy even though the basal blood pressure level was apparently not changed.

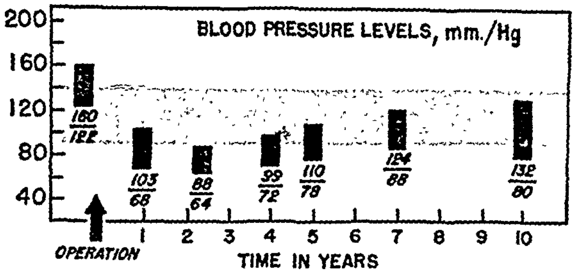

Fig. 2.—Blood pressure levels 10 years after splanchnicectomy in patient in case 1.

SELECTION OF THERAPY FOR HYPERTENSIVE PATIENTS

As pointed out earlier in this report, there are three chief modes of therapy currently available for the management of hypertensive cardiovascular disease: (1) surgery, (2) diet, and (3) drugs. In order to select the proper type of treatment for each case, it is important to evaluate the level of the blood pressure and the amount of cardiovascular disease present. Placing patients into the four groups given enables one to do this. The mortalities and survival rates for these groups then serve as a basis for selection of therapy. It should be reemphasized that only patients with persistent hypertension are meant. If the patient falls into group 1, diet and drugs comprise the usual treatment. The results following splanchnicectomy, while showing a lower long-term mortality, are not sufficiently superior to the medical results as yet to allow us to recommend surgery routinely in all such cases. This is particularly true for female patients, who appear to do well on medical therapy. It may be that group 1 men, however, should have surgery, since these patients have a considerably poorer prognosis when treated medically. Other group 1 patients who may be operated on are young patients with high resting diastolic (above 110 mm. Hg) blood pressure levels, those with intractable symptoms, those with a history of toxemia or other complications of pregnancy associated with hypertension who desire more children, and those patients who for various reasons are unable to follow a medical regimen. If the patient falls into group 2 or 3, we believe that surgery in the form of splanchnicectomy is the treatment of first choice and should be recommended. In refractory group 2 and 3 cases diet and drug therapy may have to be added to surgery to achieve maximum benefit. In group 4 cases surgery may be recommended, provided renal function is adequate and if the patient is a satisfactory surgical risk. Severe kidney damage, as indicated by persistent evidence of nitrogen retention, is the one finding that positively contraindicates splanchnicectomy in the more advanced stages of hypertensive cardiovascular disease. Although the mortality after surgery is much improved, the eventual mortality for group 4 cases is still very high. It is our belief that surgical treatment should be employed before patients are allowed to progress to group 4, if the greatest number of worthwhile results is to be obtained. At the present time the only reliable basis for the selection of patients for splanchnicectomy is the effect that surgical treatment is known to have on the life expectancy of patients in each of our four groups.

SUMMARY

A method of classifying hypertensive patients, depending on the level of blood pressure and the amount of cardiovascular disease present when first studied, is outlined. The mortalities and survival rates for 1,266 hypertensive patients treated by thoracolumbar splanchnicectomy and for 467 medically treated control patients are compared. The results following surgery are superior in all four groups (Smithwick classification), but the best results are obtained in patients who fall into groups 2 and 3. We recommend splanchnicectomy as the treatment of first choice in such cases. Patients should be operated on before they fall into group 4, since the eventual mortality for this group is high regardless of the therapy employed. An outline of our present method of selection of therapy for hypertensive patients is given, based on the known effect of surgical treatment on prognosis.

203 Commonwealth Ave. (Dr. Smithwick).

Treatment of the Thyroid Storm.—Thyroid crisis or storm represents a dramatic medical emergency. This condition was formerly encountered occasionally postoperatively when patients were inadequately prepared for surgery. It is now seen rarely in debilitated thyrotoxic patients who have been untreated for long periods and are in poor nutritional status. Treatment is begun with the application of cold compresses or ice to the entire body, including cool water enemas if marked hyperthermia is present. Demerol or morphine is used for control of severe restlessness. The patient is placed in a cold oxygen tent. Sodium iodide, 1 gram, in 1,000 cc. of 5% glucose solution is given intravenously. Sodium iodide, 500 mg., may also be given by enema. Antithyroid therapy with methylthiouracil, 600 mg., is begun immediately, then 200 mg. every six hours. Tapazole may be used in one-tenth this dosage. Sodium or potassium iodide should be continued at a high dosage level until recovery. Aqueous adrenal cortical extract should be administered as in the treatment of addisonian crisis. Further experience with cortisone or hydrocortisone is necessary for evaluation of these drugs.—M. G. Wohl, M.D., C. R. Shuman, M.D., and R. Robbins, M.D., Current Treatment of Toxic Goiter, *Medical Clinics of North America,* July, 1953.

FOLLOW-UP STUDY IN SEVENTY-FIVE CASES OF NONPARALYTIC POLIOMYELITIS

Eugene Moskowitz, M.D., Mount Vernon, N. Y.
and
Lawrence I. Kaplan, M.D., New York

Recent increases in the over-all incidence of poliomyelitis have prompted early diagnosis and hospitalization in suspected cases. This has led to the detection of a greater number of the so-called nonparalytic cases. With the advent of passive immunization with gamma globulin, as developed by Hammon and co-workers,[1] an even greater percentage of abortive and nonparalytic cases may be anticipated.

Nonparalytic poliomyelitis, as interpreted in this study, refers to cases diagnosed by clinical and laboratory findings in which the patients, at the time of discharge from the hospital, showed no evidence of muscular weakness. During routine follow-up examination of these patients in the outpatient department of Grasslands Hospital, a surprising number showed various sequelae. As a result of these casual findings, we were prompted to carry out a formal study of a large group of patients who were discharged from the hospital during the period 1947 to 1951 and who showed no muscular weakness at the time of release.

METHOD AND MATERIAL

The following procedure was adopted for the carrying out of this study. Each patient, with a parent whenever necessary, was given an initial interview, and a detailed post hospitalization history was obtained, including subjective complaints that might have been associated with poliomyelitis. Each patient was then given a complete muscle test by the chief physical therapist and afterward was thoroughly screened again by one of us. In addition to muscular abnormalities, the patients were checked for structural or postural abnormalities, including atrophy of the extremities as measured by accepted techniques (circumferences at various levels). A difference between two extremities in circumference at the same level was not in itself taken to be indicative of involvement due to poliomyelitis unless it was associated with muscular weakness. A total of 75 patients were examined, of whom 51 were children (under age 13) and 24 were adults.

RESULTS

The results of this study are shown in the following tabulation:

Total no. of patients examined	75
No. with subsequent muscular weakness	29
Percentage with subsequent muscular weakness	38.6%
Distribution of muscular weakness	
Quadriceps	11
Gastrocnemius	10
Sternocleidomastoid	4
Abdominal muscles	3
Hamstrings	3
Deltoid	2
Hip extensors	2
Triceps	1
Biceps	1
Hip flexors	1
Rhomboids	1
Anterior tibial	1

Muscular weakness was noted in 29 patients, or 38.6% of the total number of patients examined, at the time of the follow-up examination. The major segments involved were the weight bearing muscles, principally the calf and quadriceps groups. This may be explainable by the fact that all of these patients had been on only a ward activity level at the time of discharge from the hospital; therefore, there had been no adequate criterion to determine the endurance and fatigability of the weight bearing muscle groups, since these patients had not been performing their normal daily play or occupational activities.

Of the 29 patients who showed muscular weakness, 3 had some residual spasm at the time of the follow-up examination. There was no correlation between the duration of spasm in the hospital and the subsequent development of weakness. Twenty-three (30.6%) of the 75 patients examined had shown deep tendon reflex differences of varied patterns during the acute phase of the disease. Loss or diminution of tendon reflexes was not related in any way to the eventual onset of or site of muscular weakness. Seven (24.1%) of the 29 patients with subsequent weakness had symptoms referable to the segment in which the weakness was localized. A surprising number of patients (42.7%) had subjective manifestations, consisting of increased fatigability. Evidence of emotional disturbances of various types, including irritability, instability, and stuttering, were manifest in 24% of these patients. In children, increased irritability was the predominent complaint of the parents.

COMMENT

While 38.6% of a group of 75 patients with nonparalytic poliomyelitis, examined one and one-half to six years after the onset of the disease, showed weakness in one or more muscles, this is not an indication that the present methods of muscle testing should be discarded. In no instance in the above series was the muscular weakness extensive enough to appreciably interfere with the normal activities of the patient.

In the screening of mild poliomyelitis cases, either during the patients' hospital stay or during their treatment at home the diagnosis of nonparalytic poliomyelitis should not be made on the basis of a single examination. The performance of multiple, staged tests based on the general condition and activity level of the patient is pre-

Director of Physical Medicine and Rehabilitation (Dr. Moskowitz) and affiliated resident in Physical Medicine and Rehabilitation (Dr. Kaplan), Grasslands Hospital, Valhalla, N. Y., and Fellow, Department of Physical Medicine and Rehabilitation, New York University-Bellevue Medical Center and United States Public Health Service (Dr. Kaplan).

Miss Katherine Andrews, Chief Physical Therapist, Grasslands Hospital, gave technical assistance in this study.

[1] Hammon, W. M.; Coriell, L. L.; Wehrle, P. F., and Stokes, J.: Evaluation of Red Cross Gamma Globulin as a Prophylactic Agent for Poliomyelitis, J. A. M. A. **151**: 1272-1285 (April 11) 1953.

ferable. During the acute phase, in the presence of spasm, accurate performance of a satisfactory muscle test is impossible. As the acute manifestations subside, the patient is permitted a progressive increase of activities, and their effect on muscular fatigability, especially in the weight bearing groups of the lower extremities, should be determined. Actually, the diminished work tolerance in a muscle that is only mildly involved can be made manifest only after strenuous activity. Such a situation does not prevail during the early convalescent stage of the disease. In the presence of minimal weakness, variations occur in the muscle test, depending on the activity level of the patient, and would be evident, for example, in the quadriceps group in a child after two to three hours of play or in the gastrocnemius group in a policeman after completion of an eight hour shift.

In our series, the average hospital stay of the children was 24.4 days and of the adults, 14.4 days. There was no relationship between the length of hospital stay and subsequent appearance of muscular weakness. In addition, there was no correlation between the time of ambulation of these patients and the subsequent development of muscular weakness. It is not necessary to increase the hospital stay of a patient with the nonparalytic disease, provided the physician is alert to the possibility of the presence of undetected muscular weakness. As a matter of fact, during the 1952 season, 37 cases of nonparalytic spinal involvement were seen at Grasslands Hospital. The average stay for the adults was 10.6 days and for the children, 14.7 days. Each patient returned for a follow-up examination about one month after discharge, and no undetected muscular weakness was noted at these visits. Each patient in this group in whom there was spasm received hot packs routinely and was permitted to get out of bed as soon as he had been afebrile for five days and had no residual muscle spasm. These patients were closely supervised when allowed to become ambulant as a further check for muscular weakness and were cautioned to carry on at a restricted activity level at home until they returned for the follow-up examination.

SUMMARY

Of 75 patients with nonparalytic poliomyelitis examined one and one-half to six years after the onset of the illness, 38.6% were found to have minimal weakness in one or more muscle groups. Seven (24.1%) of these patients had symptoms referable to the site of muscular weakness. Increased general fatigability was complained of by 42.7% of the 75 patients examined, and 24% had evidences of emotional disturbances, such as irritability, instability, and stuttering.

CONCLUSIONS

1. The diagnosis of nonparalytic poliomyelitis should be made only after complete muscle testing has been done after the patient has resumed his or her normal physical activity level.

2. The average hospital stay of the patient with nonparalytic poliomyelitis can be significantly reduced, provided the patient is free of spasm and has had multiple screenings for muscular weakness.

3. In the absence of muscle spasm and respiratory difficulties, early mobilization under adequate medical supervision of the afebrile patient with nonparalytic poliomyelitis has no adverse effect on the eventual functional recovery of the patient.

Grasslands Hospital, Valhalla, N. Y. (Dr. Moskowitz).

NEW YORK CITY PLAN FOR CARE OF POLIOMYELITIS PATIENTS IN RESPIRATORS

Helen M. Wallace, M.D.
and
Leona Baumgartner, M.D., New York

The problem of patients with poliomyelitis who need care in a respirator is becoming a matter of concern to those interested in the field of long-term illness or chronic disease. The basic problems are, of course, the increase of fundamental understanding of the epidemiology of poliomyelitis and the development of methods of preventing the disease. Considerable progress is being made in these areas. There is, nevertheless, the immediate problem of adequate care of poliomyelitis patients. Public health officials, hospital administrators, and physicians have paid particular attention to the care of poliomyelitis patients in the acute stage of illness and to the rehabilitation of those patients who are orthopedically handicapped. The problems of those patients who need care in a respirator seem to have received less attention, although a few communities are attempting to develop communitywide programs for such patients. According to information from the National Foundation for Infantile Paralysis, there are approximately 1,000 patients in the country who require care in a respirator and there are seven respirator centers that can accommodate about 230 of these patients.[1] There is also evidence of interest in the development of additional centers, but no report of a community planning for the care of its own patients has been found in the literature. The materials presented in this report pose a few of the questions that arise when a community program for patients with poliomyelitis who require care in respirators is envisaged, and a few of the answers found in a recent study of the situation in New York City are given. A few of the questions to be answered are: 1. How many patients in the community will need care in a respirator? 2. What are the problems in the care now given to such patients in the community? 3. How much will adequate care cost?

From the Bureau for Handicapped Children, New York City Department of Health.

Presented at the Section on Pediatrics, New York Academy of Medicine, May 14, 1953.

[1] Landauer, K.: Personal communication to the authors.

INCIDENCE AND PREVALENCE

During the past 36 years in New York City, 29,002 cases of poliomyelitis have been reported to the New York City Department of Health, an average of 805.6 cases each year. In 29 of the 36 years (80%), less than 800 cases were reported. More than 1,000 cases per year occurred in 1916, 1931, 1935, 1944, 1949, and 1950. The percentage of hospitalized poliomyelitis patients who need respirator care has not been uniform. For example, in 1949 and 1951, hospitals in New York City reported that the percentage of patients requiring respirator care varied from 5 to 10%. This percentage obviously depends on several factors: (1) the indications for the use of a respirator determined by the medical staff in each hospital, (2) the care with which each patient's condition is evaluated against such indications, and (3) the severity of the disease. In planning adequate facilities one might assume that 8% of those patients hospitalized for poliomyelitis will need respirator care; thus, in New York City, it is calculated that, on an average, about 64 persons might need respirator care in any one year (8% of 800), exclusive of epidemic years.

In 1951, a nonepidemic year in New York City, 548 cases of poliomyelitis were reported to the New York City Department of Health. Observations in hospitals in the city during the latter part of December, 1951, and the early part of January, 1952, revealed a total of 19 respirator patients in five hospitals. The largest number of patients in any one hospital was nine; the smallest number was one. At the same time, it was known that at least five patients in respirators were being cared for at home. At least another eight had been transferred out of the city to the nearest respirator center, approximately 250 miles away, and additional patients had also been transferred to another respirator center in the East.

CARE AVAILABLE

In planning a community program for any type of patients, including those requiring respirator care, one of the first questions asked is "How good is the care now available?" Many assume that, because there are outstanding medical centers in large urban areas, the care available there is far above the usual standards. Our observations have not uniformly substantiated this assumption. The problems found on visits by a pediatrician and a hospital nursing consultant to these hospitals included lack of adequate physical facilities, of continuous medical supervision, of qualified nursing supervision, and of an adequate rehabilitation program.

An analysis of the five hospitals that provided care for respirator poliomyelitis patients in New York City in 1951 and 1952 revealed the following facts. Of the five hospitals, the pediatric staff was in charge in three and the neurology staff in one. In the fifth hospital, respirator patients were cared for by three separate services in the hospitals, pediatric, neurology, and medicine, each with its own space, physical set-up, equipment, and medical and nursing personnel. Obviously this plan meant a dispersion of nursing staff and supervision and some duplication of facilities and equipment. All the hospitals, are approved for training pediatric interns and residents by the Council on Medical Education and Hospitals of the American Medical Association, three for training in orthopedic surgery, and two for training in physical medicine and rehabilitation. Furthermore, of the five hospitals, three did not have or provide a physiatrist for consultation and supervision of the patients for the purposes of physical therapy and rehabilitation, and two did not have an orthopedist. Three of the hospitals provided physical therapy and occupational therapy staffs that could be considered adequate. The fourth hospital had some therapists but too few to give adequate care to all of the patients who needed it. The fifth hospital provided neither physical therapy nor occupational therapy. To illustrate the problem in terms of patient care, one hospital without such personnel had three poliomyelitis patients on the day of the visit. Two were in respirators. The three patients had been hospitalized for approximately five months each; none had received any physical therapy during this period of time. One of the patients had developed contractures of the arms at the elbows during this period.

Recreational staff was provided in one of the five hospitals. Most of the recreational activities in the other four hospitals consisted of watching television programs. In one hospital, the recreational program consisted of a private duty nurse, employed at the rate of $12 for each eight hours of duty, who read to the patient. With appropriate recreational activities, earlier rehabilitation might have been possible.

Many problems in the nursing care of patients were observed. In three hospitals, the regular hospital nursing staff cared for these patients; in another, nurses on a private duty basis were employed at a cost of $36 per patient for 24 hours; in the fifth, a combination of regular staff plus private duty nurses was used. Waste of nursing staff and time was evident. The illustration of the private duty nurse reading to the patient is but one example. In other instances, nurses carried out procedures such as autoclaving letters written by patients and covering patients with mosquito netting. A supervising nurse in one hospital expressed the opinion that the employment of private duty nurses on a daily basis was not the solution to the care of respirator patients because many of these nurses had not seen a respirator or a respirator patient in a good many years, if ever, and because private duty nurses received more salary than general hospital staff nurses and that created friction between the two groups.

Other nursing problems are illustrated by the situation in one hospital that had nine respirator patients, eight in two wards in one building and the ninth in another building. For the eight patients, there was no registered nurse on duty from 12 midnight until 8 a. m.; from 3 p. m. to 12 midnight there was one registered nurse who covered the two floors. These patients were cared for entirely by nonprofessional nursing personnel without nursing supervision. The ninth patient was cared for by student nurses and attendants only.

Similar problems existed in other areas of patient care also. Four of the hospitals provided a teaching staff for educational activities so that the children could continue their schooling during the period of hospitalization. The fifth hospital had no such teaching staff; the family of one child demanded that their child who had been there six months be transferred to the nearest respirator center where teaching and other services could be provided.

Four hospitals had facilities for bronchoscopy and tracheotomy and had a trained staff on call to perform these emergency procedures. The fifth hospital had a trained staff on call, but no facilities or equipment in the building in which the respirator patients were. It is evident that, if these services are needed, they are usually emergencies and, therefore, must be readily available.

Three hospitals provided psychiatric help for patients; two did not. Because of the psychological factors involved in caring for handicapped patients and in weaning patients from respirators, psychiatric consultation is certainly important in their rehabilitation.

Three of the hospitals transferred patients to the nearest respirator center 250 miles away. Reasons given for the transfer of these patients were: (1) recognition by the staff of the hospital that they were not prepared, equipped, or staffed to provide adequate rehabilitation for their patients; (2) requests by the families of patients because of some dissatisfaction with the care given; and (3) reluctance on the part of some of the hospitals to provide the long-term care that might be necessary.

COST OF CARE

The care of patients in respirators is costly. Skillful nursing, oxygen, and ancillary therapy services are items that contribute appreciably to cost. Cost figures could not be obtained from the hospitals visited. Even if they had been secured, they would probably have been of limited value because of two expensive practices, employment of private duty nurses at $36 a day and excessive use of oxygen in one hospital in which all respirator patients there received oxygen routinely and continuously. Data obtained from five respirator centers throughout the country indicate daily costs ranging from $18 to $23.

Data on the length of hospital stay for respirator poliomyelitis patients are even more difficult to obtain or evaluate. They, of course, may be directly dependent on each hospital's ability to evaluate the patient's condition and its ability to provide the necessary physical therapy and psychiatric services to wean the patient from the respirator as quickly as possible. No reliable data on length of stay were obtainable from observations in New York City hospitals.

COMMUNITY PLAN

When all of the facts were put together, it became evident that a community plan was necessary, if respirator patients were to receive the quality of care necessary for their rehabilitation by a method most economical to the community as a whole. Conferences were held with medical leaders in the city who have worked on the problem of the care of poliomyelitis patients. The New York City Department of Health, in the spring of 1952, appointed an advisory committee composed of leaders in the clinical care of poliomyelitis, pediatrics, physical medicine and rehabilitation, orthopedics, nursing, and representatives of the local chapter and national office of the National Foundation for Infantile Paralysis. Dr. Rustin McIntosh served as chairman of this committee.

At the first meeting of this committee, there was considerable discussion concerning several basic questions. Is it possible for many hospitals, each caring for only a few patients in respirators, to provide adequate total care, or is it more likely that a few respirator centers, each caring for many patients, could provide care of a high quality for maximum and early rehabilitation? If respirator centers are developed, should these centers provide care for both acute and chronic respirator patients, including those patients requiring custodial care? If respirator centers are developed, would it be helpful if standards were available to assist interested hospitals in planning facilities; if so, what should the standards contain? If respirator centers are developed, should they be a part of general hospitals? After much discussion, the committee recommended that one or more respirator centers be developed in the city, that the committee establish recommended standards, and that the centers preferably be attached to general hospitals so that the necessary ancillary services would be readily available.

In developing standards, the experience of existing centers throughout the country was called on. These standards were established by the advisory committee. The final approved standards[2] consist of sections concerning personnel of all types, physical set-up, essential equipment, techniques, policies and procedures, and home follow-up after discharge from the center.

Considerable joint planning has been done by the city health and hospitals departments, the National Foundation for Infantile Paralysis, and interested voluntary hospitals to develop centers of high caliber in the city. The approved standards are being used as a guide in the development of these centers. Two centers are currently being planned, one in a voluntary hospital and the other in a municipal hospital in conjunction with a large rehabilitation program. Both of the centers will carry on training and research activities in addition to the patient care program. The training and research activities logically belong to the large teaching hospitals connected with medical schools; for this reason, the two hospitals currently considering plans for respirator centers fall into this category.

While the plans for assisting hospitals in financing the centers are not completed, some steps have already been taken. The New York City Department of Health has asked for budgetary approval of a daily rate of $20 for the care of patients requiring financial aid in approved centers as part of the medical rehabilitation program of the Bureau for Handicapped Children. The National Foundation for Infantile Paralysis is considering possibilities of subsidy for the development of the program in the centers.

SUMMARY

This report describes the steps being taken in New York City to provide an improved quality of care for the maximum rehabilitation of poliomyelitis patients in respirators. Surveys of hospitals caring for respirator patients in the city in 1951 and 1952 showed a wide variation in the kind and quality of care given. An advisory committee was formed and was composed of experts in the field. This committee endorsed the principle of respirator centers and set up standards to be used as guides in the development of these centers. Two such centers are being developed in the city.

POSTOPERATIVE ADRENAL CORTICAL INSUFFICIENCY

OCCURRENCE IN PATIENTS PREVIOUSLY TREATED WITH CORTISONE

Robert M. Salassa, M.D., Warren A. Bennett, M.D., F. Raymond Keating Jr., M.D.
and
Randall G. Sprague, M.D., Rochester, Minn.

Although therapeutic experience with cortisone has been accumulated rapidly during the past four years, the limits of therapeutic usefulness and the hazards of this and similar compounds still await precise definition. There is considerable evidence to support the view that the administration of adrenal cortical hormones may suppress adrenal function and induce adrenal atrophy. The extent, duration, and potential seriousness of this hazard in medical and surgical practice are, however, only now becoming apparent. A year ago, Fraser and coworkers[1] reported a postoperative death that was regarded as the result of acute postoperative adrenal cortical insufficiency associated with atrophy and functional suppression of the adrenal cortex induced by previous treatment with cortisone. We wish to describe two additional examples of the same surgical complication, with further observations on the occurrence in man of adrenal atrophy induced by cortisone.

REPORT OF CASES

Case 1.*—A woman, 54 years of age, entered the Mayo Clinic on Oct. 31, 1951, because of rheumatoid arthritis and epigastric distress. Four years previously, the presence of severe pain and stiffness of the joints of the hands, wrists, knees, and shoulders led to a diagnosis of rheumatoid arthritis. Beginning one year before admission, she was given 75 mg. of cortisone three times a week. After four months, the dose was increased to 100 mg. a day. She gained 20 lb. (9.1 kg.), and noticed an increase in roundness in the face and a coarsening of features. For three or four weeks before admission she complained of epigastric distress that occurred between meals, and, because of this, the dose of cortisone was reduced to 75 mg. per day.

Examination disclosed swelling and tenderness of many joints. The blood pressure was 160 mm. Hg systolic and 80 mm. Hg diastolic. The face was full. The erythrocyte count was 3.7 million per cubic millimeter; the hemoglobin content was 7 gm. per 100 cc.; the blood smears were characteristic of hypochromic microcytic anemia. Roentgen examination of the stomach revealed a penetrating gastric ulcer on the lesser curvature proximal to the pylorus. Melena was noted while the patient was in the hospital.

On Nov. 7, the patient vomited dark-brown material and suffered severe pain in the epigastrium. The blood pressure dropped, and she became cold and restless. Three transfusions totalling 2,000 cc. were given. The dose of cortisone during this period was 50 mg. per day by mouth. On Nov. 12, the dose was reduced to 37.5 mg. This dose was continued until 6 p. m., Dec. 5, when an additional 100 mg. of cortisone was given intramuscularly. On Dec. 6, a subtotal gastrectomy (Billroth I, Schoemaker modification) was carried out. The patient remained semiconscious after the operation; signs of shock appeared; and she became anuric. Despite the intramuscular administration of 300 mg. of cortisone, the woman failed to respond to emergency measures and died 30 hours after operation.

Postmortem examination was carried out 12 hours after death. The right pleural cavity contained 500 cc. and the left 150 cc. of clear yellow fluid. The heart weighed 305 gm. and was normal. The lungs weighed 1,020 gm. and showed marked congestion and edema, with patchy bronchopneumonia. The spleen and liver were normal except for slight congestion. The suture lines at the site of the recent gastrectomy were intact. The esophagus, duodenum, pancreas, bladder, kidneys, uterus, ovaries, breasts, and thyroid appeared normal.

The adrenal glands were quite atrophic; the right weighed 2.7 gm. and the left 3 gm. (fig. 1*A*). The cortex was 2 mm. thick. The bright yellow color usually seen was absent. Microscopically, there was almost complete absence of the vacuoles usually seen when the sections are stained with hematoxylin and eosin. With Sudan 4 stain, diminished quantities of lipid were noted throughout all zones (fig. 1*B*). The medulla appeared normal. The pituitary body was smaller than normal, and microscopic sections disclosed a loss of granularity in the basophils, with hyalinization and vacuolization (fig. 1*C*). (See fig. 3 for comparison with the normal gland.)

The shock and anuria that followed operation in this patient did not seem commensurate with the uneventful operation and anesthesia that preceded it. The appearance of hypercortisonism and the changes observed in the adrenal and pituitary glands at necropsy constituted the only positive necropsy findings apart from pulmonary edema. They appeared to offer adequate evidence for the assumption that the final shock was due to acute adrenal cortical insufficiency resulting from prior cortisone therapy.

Case 2.—A woman, 54 years of age, entered the Mayo Clinic on Aug. 18, 1952, for treatment of rheumatoid arthritis. Eight years previously, swelling of the right distal interphalangeal joints and of the right instep and heel occurred. Subsequently, the hands, feet, knees, elbows, ankles, and shoulders became progressively involved, with many acute episodes of joint pain and swelling in various locations. In 1949, the patient was treated with colloidal gold and in 1950 and 1951, she received four courses of cortisone or corticotropin (ACTH) by injection; this was interspersed sporadically with cortisone given orally. During the preceding year, she received two injections of cortisone a week, and, on eight occasions, two injections per day for one week. During the vigorous treatment with cortisone, she noticed a rounding of her face. A year previously, a cystocele and a rectocele had been repaired without untoward reaction while the patient was receiving substantial doses of cortisone.

Examination disclosed a blood pressure of 122/80 mm. Hg. The patient weighed 120 lb. (54.4 kg.). The ankles were slightly edematous, and the face was round and florid. The joints of the fingers and knees were deformed, and there was tenderness over the lumbar part of the spinal column. The sedimentation rate was 115 mm. in one hour. Treatment with cortisone was discontinued on the patient's admission. A total of 422 mg. of hydrocortisone was injected into the knees, left shoulder, and ankles on six occasions between Aug. 23 and Dec. 22. There was little untoward reaction to withdrawal of cortisone after

* The relationship of gastrointestinal lesions to cortisone therapy in this case is discussed in detail by Sauer, W. G.; Dearing, W. H., and Wollaeger, E. E.: Gastrointestinal Manifestations Possibly Related to the Administration of Cortisone and Corticotropin, Proc. Staff Meet., Mayo Clin., to be published.

the first two weeks. Signs of hypercortisonism persisted for about six weeks after withdrawal of the drug. On Nov. 3, urinary excretion of 17-ketosteroids was 1 mg. per 24 hours.

On Jan. 7, 1953, a bilateral bunionectomy was performed. The patient withstood this procedure well, but 15 hours after operation irreversible shock developed. Despite treatment with 125 mg. of cortisone given intramuscularly and 100 mg. of hydrocortisone given intravenously 30 minutes before death, the woman died 16 hours after the operation.

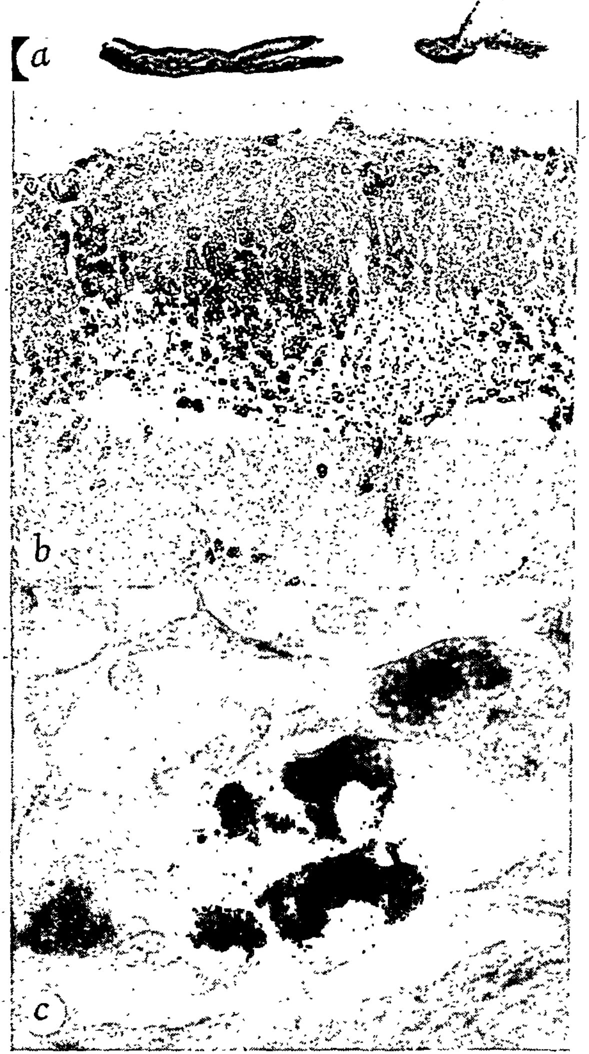

Fig. 1.—Specimens in case 1: *A*, gross appearance of adrenals (5.7 gm.) showing marked atrophy of cortex with zone of congestion in the zona reticularis; *B*, adrenal showing loss of sudanophilic material in all zones of the cortex, irregular loss in zona fasciculata, and narrowing of cortex (Sudan 4 stain, × 55); and *C*, cross section of pituitary showing loss of granules in cytoplasm of basophils and hyalinization with vacuolization in two cells (Crooke's stain, × 1,050).

At post mortem, the lungs weighed 755 gm., and moderate pulmonary edema was evident on microscopic examination. Focal areas of organizing lipid pneumonia were also observed. The heart, spleen, liver, gastrointestinal tract, pancreas, kidneys, bladder, ovaries, and breasts appeared normal. The thyroid contained several cystic and degenerated colloid adenomas. The right adrenal weighed 3.8 gm. and the left 3.7 gm. (fig. 2*A*). Examination of routine microscopic sections revealed that the adrenal cortex was approximately 1 mm. thick and that there was loss of vacuolization and increase in granularity of the cells of the zona fasciculata. With Sudan 4 stain, there was evidence of diminished lipid throughout the zona fasciculata and zona reticularis, with a patchy decrease in lipid in the zona glomerulosa (fig. 2*B*). The medulla was normal. There was no apparent decrease in the number of cells in the adrenal cortex, but the cells were smaller than normal. The nuclei were prominent.

The pituitary weighed 0.6 gm. (normal weight 0.7 to 1.1 gm.). The cut surface was glistening yellow-white with irregular follicles. Microscopic examination disclosed a decrease in the number of basophils. Most of the basophils showed degranulation with hyalinization and vacuolization (fig. 2*C*). This alterative process involved all the basophils; no normal basophils could be found.

Except for six intra-articular injections of hydrocortisone, this patient had not had steroid hormone therapy for four and a half months preceding operation. On admission she had severe hypercortisonism, clinical manifestations of which had disappeared three months before operation. Although urinary 17-ketosteroids were greatly reduced two months preceding operation, a finding suggesting adrenal suppression, the long interval without cortisone undoubtedly led to the false assumption that a mild surgical procedure could be undertaken without preoperative treatment. Nevertheless, symptoms consistent with fulminating acute adrenal insufficiency devel-

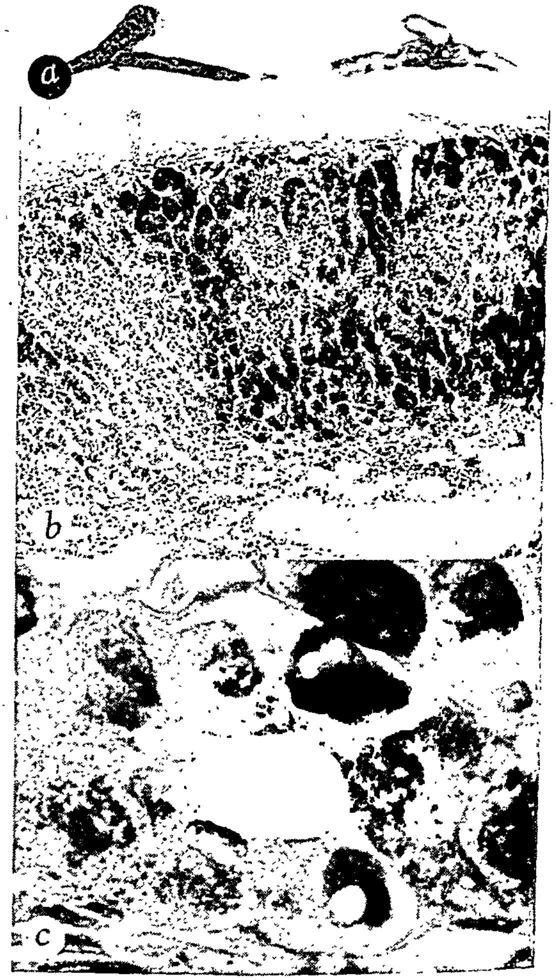

Fig. 2.—Specimens in case 2: *A*, gross appearance of adrenals (7.5 gm.) showing atrophy of adrenal cortex, with congestion of the zona reticularis; *B*, adrenal showing disease of sudanophilic material in zona glomerulosa and irregular areas of diminished lipid in other two zones (Sudan 4 stain, × 55); and *C*, pituitary showing loss of granules in cytoplasm of basophils, a few hyalinized basophils, and vacuolated changes similar to Crooke's changes in basophils (Crooke's stain, × 1,050).

oped 14 hours postoperatively, and the patient died despite emergency measures. The atrophy of the adrenals and pituitary constituted the only significant necropsy findings and provided anatomic support for the conclusion that the suppressive effect of prior cortisone therapy was the cause of the postoperative adrenal cortical crisis and death, even though treatment with cortisone had been discontinued four and a half months before.

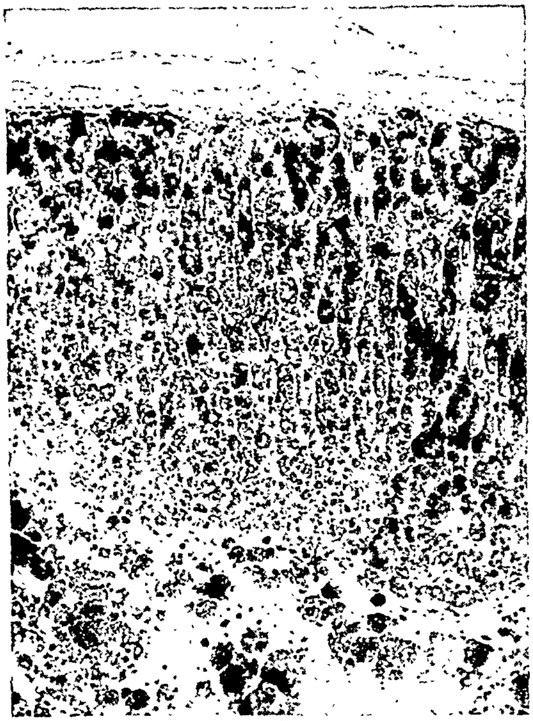

Fig. 3.—Adrenal gland illustrating normal pattern of three distinct zones of adrenal cortex (Sudan 4 stain, × 55).

ADDITIONAL OBSERVATIONS ON ADRENAL CHANGES

In order to investigate the occurrence of adrenal atrophy further, the weights of the adrenal glands of 46 adult patients who died of various conditions for which they had received cortisone were compared with the weights of the adrenal glands of 42 patients who died of similar conditions but who had never received cortisone. These data are summarized in figure 4. While the average adrenal weight was significantly decreased in the group treated with cortisone, conspicuous adrenal atrophy occurred in only a small proportion of cases. The relationship of adrenal atrophy to the duration and time of treatment is given in detail in the table.

In nine patients who received cortisone for less than five days (four received it until the day of death), adrenal weights were always within the normal range and histological changes were lacking. The most consistent reduction in adrenal weight occurred in 10 patients who received cortisone for five or more days and until the day before death. The mean weights of the adrenals were significantly reduced in the groups of patients who were treated with cortisone for five or more days and in whom treatment with cortisone was discontinued within 20 days before death; in the groups of patients in whom treatment with the drug was discontinued for at least 21 days before death, there was no significant reduction in the mean weights of the adrenals. The data obtained are too limited to permit further correlation with either dose or duration of therapy.

It is important to note, however, that pronounced adrenal changes were observed on histological examination in a great majority of the patients who received cortisone, even though the combined weights of the adrenals were well within the normal range. This is illustrated in figure 5 showing marked loss of lipid material in the zona fasciculata and the zona glomerulosa of adrenals that were normal in weight (13.7 gm.) and gross appearance. The patient received cortisone in a dose of 100 mg. a day for 13 days until 16 days before death from subacute lupus erythematosus.

Relationship of Adrenal Atrophy to Duration and Time of Treatment

Group	No. of Cases	Adrenal Weight, Gm. Range	 Mean ± S. E.*	 P †
Untreated	42	8.0-19.2	12.6 ± 0.5	—
Treated, total	46	5.0-16.8	9.8 ± 0.4	0.01
Less than 5 days	9	10.6-14.4	11.8 ± 0.4	0.1
5 days or more	37	5.0-16.8	9.2 ± 0.4	0.01
Treated until death	10	5.7- 9.8	7.9 ± 0.5	0.01

† P = probability.

The changes in the adrenal cortex that seem to be characteristic of previous cortisone administration appear to be loss of lipid content of cells of both the zona glomerulosa and the zona fasciculata. Where this has occurred, an eosinophilic granular cytoplasm is seen. The cells shrink and cause decreased thickness of the cortex, but there is no apparent decrease in the number of cortical cells. Rather, they appear to be compressed, with an increase in the nuclear-cytoplasmic ratio. In adrenals examined after treatment with cortisone has been omitted for several weeks or months, evidences of recovery are seen. These consist of the appearance of more lipid material in the cells of the zona glomerulosa and the outer portions of the zone fasciculata. This material seems to replace the granules of the cytoplasm with vacuoles of

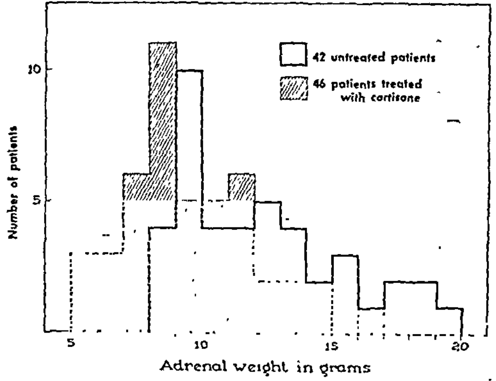

Fig. 4.—Adrenal weights of 46 patients treated with cortisone compared with adrenal weights of 42 patients not treated with cortisone.

varying size that, on frozen section, are filled with sudanophilic substance or lipid. This process proceeds in a patchy fashion, and in some areas there may be island-like projections throughout the thickness of the cortex. The zona reticularis loses its lipid last and often maintains a certain amount of lipid even in the severest cases in which it is depleted in the other zones.

PRIOR OBSERVATIONS

The earliest observations of adrenal suppression by adrenal hormone were clinical. Eighteen years ago, Kepler [2] stated: "In the presence of a hyperfunctioning tumor of one adrenal gland, the other may be absent or atrophic. Even when normal, the other gland apparently may temporarily cease to function after operation. Following surgical procedure, it is advisable to observe the patient carefully for acute adrenal insufficiency, and if this develops, to administer promptly the adrenal hormone and saline." A review of the literature some years later indicated clearly that if such a plan of management was followed, then the mortality rate that followed removal of a hyperfunctioning adrenal cortical tumor was extremely low, whereas if it was not, the mortality rate was extremely high owing almost entirely to postoperative adrenal cortical insufficiency.[3] The evidence reported here provides ample reason to regard postoperative patients just relieved of hyperfunctioning adrenal cortical tumors and postoperative patients previously treated with cortisone as suffering from the same physiological defect in adrenal function.

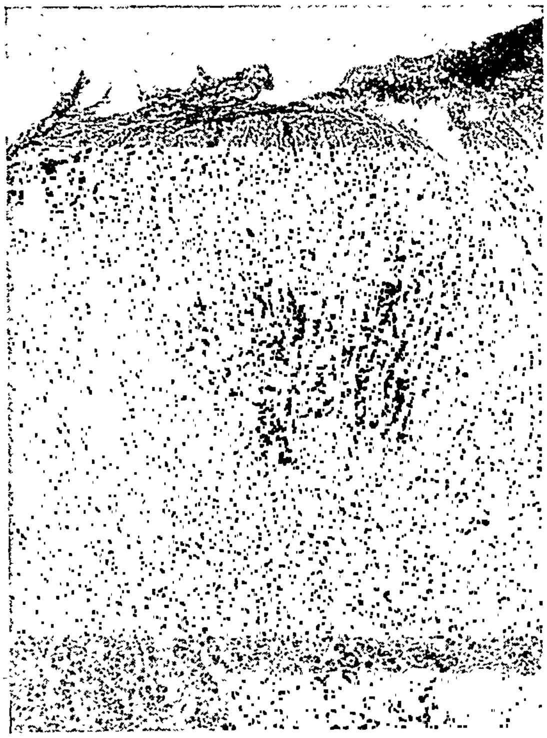

Fig. 5.—Section of adrenal glands of normal weight (13.7 gm.) in patient who received 1.3 gm. of cortisone; most of sudanophilic material lost (Sudan 4 stain, × 55).

Experimental Data.—In 1937 and 1938, Ingle and his associates [4] demonstrated that administration of adrenal cortical extract, cortisone, and compounds A and B resulted in atrophy of the adrenal cortex of rats. Winter, Silber, and Stoerk [5] observed that parenteral administration of 3 mg. of cortisone a day for 10 days reduced the adrenal weight of rats by 40%. After omission of cortisone, recovery was detectable in 4 days, well advanced in 10 days, and complete in 45 days. Other authors have reported atrophy of the adrenal cortex of rats after five days of cortisone administration.[6] Stebbins [7] observed that the glandular parenchyma was restored to normal appearance 17 days after the administration of cortisone was discontinued.

It is generally agreed that the atrophy of the adrenal cortex induced by exogenous adrenal steroids is entirely the result of decreased secretion of endogenous corticotropin by the anterior pituitary. Clear-cut evidence that this is the case was first provided by Ingle,[8] who demonstrated that adrenal atrophy did not occur in normal rats or rats having had a hypophysectomy that were given adrenal hormones when pituitary extract containing corticotropin was also given. Stebbins [9] found that administration of cortisone could not further reduce the adrenal weight in rats having had a hypophysectomy, while Lewis and co-workers [10] also found that cortisone would not induce atrophy of the adrenal cortex of similarly treated rats maintained on corticotropin. The concept that adrenal cortical atrophy resulting from cortisone reflects diminished production of corticotropin gains further support from the observation that the histological appearance of the adrenal cortex of rats treated with cortisone is similar to that of rats that have had a hypophysectomy.[11] Sayers and Sayers [12] have demonstrated that a variety of adrenal cortical hormones, particularly cortisone and hydrocortisone, can inhibit the release of corticotropin in rats subjected to various forms of stress. Golden and Bondy [13] observed Crooke's changes in the basophils of the anterior pituitary as well as atrophy of the adrenal cortex after giving rats 3 mg. of cortisone a day for 10 days. Administration of 1 mg. of corticotropin per day resulted in similar extensive Crooke's changes in pituitary basophils, but these were, of course, accompanied by marked adrenal cortical hyperplasia.

Clinical Observations.—Clinical studies [14] have disclosed the following evidence suggestive of depressed adrenal cortical function following treatment with cortisone in man: 1. Many patients have complained of weakness and fatigability that persisted for variable periods of time after withdrawal of cortisone. 2. Urinary excretion of 17-ketosteroids sometimes decreased soon after administration of cortisone, and this diminished excretion sometimes persisted throughout the period of therapy and for a variable period afterward. 3. The ability of the adrenal cortex to respond to one or several doses of corticotropin, as measured by decreased concentration of eosinophils or by increased urinary excretion of 17-ketosteroids or of 17-21-hydroxy-20-ketosteroids, is diminished by long-term administration of cortisone.

Adrenal cortical atrophy has been found at necropsy in some patients who received cortisone.[15] O'Donnell and co-workers [15b] found evidence of histological repair in one case in which death occurred 17 days after cortisone was last given. In a second patient with multiple myeloma who had received 6 gm. of cortisone in 31 days (the last dose given 51 days before death), the zona reticularis and the zona fasciculata were mildly hypertrophic.

Fraser and associates [1] observed fatal postoperative adrenal insufficiency after an orthopedic operation. The patient had received a large amount of cortisone; the dose was reduced to 25 mg. twice a day two months before operation and discontinued two days before operation. The patient apparently did not have hypercortisonism at any time. At necropsy, atrophy of both adrenals was observed.

In patients with Cushing's syndrome resulting from a hyperfunctioning adrenal cortical tumor, Crooke's changes with increase in pituitary basophils have been observed.[16] In some instances of this condition, objective evidence of adrenal insufficiency has persisted as long as a year after removal of the hyperfunctioning tumor (observation at the time of operation showed that atrophy existed in the opposite adrenal gland). Laqueur [17] observed Crooke's changes in pituitary basophils of patients treated with cortisone. Golden and associates [18] have found both Crooke's changes and an increase in the number of pituitary basophils of patients treated with corticotropin.

Kilby and Bennett [19] have recently correlated various morphological changes observed in the pituitary with the amount and duration of therapy with corticotropin or cortisone in 77 cases. The earliest changes observed were degranulation of basophils, with formation of homogeneous cytoplasm that presented an appearance of ground glass. This was followed by vacuolization of basophils with increased hyaline material in the cytoplasm; this material was situated at the periphery initially but then progressively involved most of the cytoplasm. At this stage, the appearance strongly resembled the changes described by Crooke [16] in 1935 in the pituitaries of patients with Cushing's disease. The cytoplasm often appeared to be reticulated with an increase in the size of cells and in the nucleolar-nucleus ratio [20] (these may represent the amphophils of Mellgren). In cases in which treatment resulted in hypercortisonism, most of the basophils showed hyalinization with vacuolization of the cytoplasm. These changes were associated both with cortisone and with corticotropin therapy, but they were most pronounced in those cases in which corticotropin was given; they occurred after relatively small doses of this substance. The smallest dose of cortisone resulting in pituitary changes was 100 mg. a day for four days. This was also accompanied by adrenal changes of the type previously described.

From the evidence presented it seems reasonably clear (1) that cortisone is capable of producing atrophy of the adrenal cortex, (2) that this atrophy may be associated with impaired adrenal cortical function, (3) that both the atrophy and the accompanying functional impairment may outlast (perhaps occasionally for a long time) the withdrawal of cortisone, (4) that adrenal atrophy and impaired function may lead to acute adrenal cortical insufficiency in the face of sufficient stress, such as an operation, and (5) that these effects are due entirely to suppressed production of endogenous corticotropin by the patient's pituitary. This implies, of course, that administration of corticotropin may have the same hazard as the administration of cortisone.

It has been suggested that the use of corticotropin instead of, or together with, cortisone or hydrocortisone will eliminate the risk of impaired adrenal insufficiency. From what is known of the action of exogenous corticotropin, this seems quite improbable. The activity of exogenous corticotropin is of short duration, and, while the resulting adrenal hyperplasia may last for some interval after discontinuing treatment with corticotropin, there is reason to doubt that increased functional activity of the adrenal cortex does so. Since corticotropin appears as effective as cortisone in producing histological changes in the pituitary gland in man and experimental animals, it would seem safest to assume that the endogenous secretion of corticotropin is depressed by exogenous corticotropin and that postoperative adrenal insufficiency is just as likely to follow corticotropin therapy as cortisone therapy.

CLINICAL EVALUATION OF SURGICAL RISKS

The large number of conditions for which cortisone is employed and the large number of patients to whom it is given represent an important clinical problem that must be considered whenever any patient is to undergo surgical treatment. The clinical problem entails (1) the selection from among patients who have ever been treated with cortisone or corticotropin those likely to have sufficiently impaired pituitary and adrenal function to be liable to the development of adrenal cortical insufficiency as a result of surgical stress, (2) the prevention of adrenal cortical insufficiency in those patients whom the clinician considers susceptible, and (3) the treatment of postoperative adrenal cortical insufficiency when it appears in those instances in which clinical acumen was poor or prophylactic replacement therapy was withheld or inadequate.

It is difficult, at present, to decide which patients are liable to adrenal cortical insufficiency as the result of previous therapy with adrenal or pituitary hormones. Since such complications apparently have not been observed frequently and since many thousands of patients who previously have received cortisone or corticotropin must have been operated on, it is probable that many such patients are able to withstand the stress of an operation uneventfully and without replacement therapy.

How then is one to determine which few patients are liable to adrenal insufficiency and should receive prophylactic replacement therapy? If all patients are to be protected from all potential hazards, we may be obliged to act on the basis of what we do not know rather than on the basis of what we do know. We do not know the minimal or maximal interval that must elapse after withdrawal of cortisone before the suppressive effect may be considered to be certainly abolished. It would be most unwise to assume that this interval is short. On present evidence, it seems safest to suppose that any patient who has received cortisone in significant quantities within three to six months should receive prophylactic therapy. Patients with marked hypercortisonism (whether of natural origin or induced by medication) may be more liable to persistence of impaired pituitary and adrenal function than those who have merely had maintenance therapy. On the basis of case 2, as well as past experience with the postoperative behavior of hyperfunctioning adrenal tumors, we feel that any patient who has had severe hypercortisonism within one to one and a half years before an operation should perhaps be treated as though he were liable to acute adrenal insufficiency.

We do not know the shortest period of treatment that will produce adrenal suppression. There is evidence that suppression may occur in some instances after five days of treatment with cortisone. We do not know the minimal dose of cortisone that will impair adrenal function. Theoretically, any dose equalling or exceeding the daily physiological requirement may suppress endogenous function. This may not be a very large dose; perhaps a dose of only 20 mg. of cortisone a day may be suppressive. We do not know that there is any reason to consider such minimal doses any less dangerous than much larger ones, except perhaps in cases in which frank hypercortisonism has occurred. Lastly, while it is quite evident that there exists a great deal of individual variation in susceptibility or resistance to pituitary and adrenal suppression, we do not know how to anticipate or measure such individual variations.

It is difficult to say what reliance should be placed on tests of adrenal cortical function. Urinary excretion of corticosteroids or 17-ketosteroids, response to administration of corticotropin in terms of both depression of eosinophils and changes in urinary excretion of steroids, the "water test," and the Cutler-Power-Wilder test are all procedures that give some measure of adrenal function. If these indicate impaired adrenal function, they should, of course, be taken seriously in evaluating surgical risk. Unfortunately, in the current state of knowledge, it may not be safe to assume that a patient with normal responses to such procedures possesses adrenal cortical function entirely adequate to cope with the stress of an operation. The only entirely reassuring measure of the ability of the adrenal cortex to function safely would be its response to a stress comparable to that represented by the proposed surgical procedure. Since this is not possible at present, every patient who has been exposed to cortisone therapy in the terms that have been described should be regarded during and after a surgical procedure as potentially liable to the development of postoperative adrenal cortical insufficiency.

PREOPERATIVE AND POSTOPERATIVE MANAGEMENT

In those instances in which the clinician regards postoperative adrenal cortical insufficiency a serious hazard, preoperative or prophylactic treatment may be given. The purpose of such preoperative treatment is to provide a sufficient depot of adrenal steroid in the muscle to insure an adequate and continuing supply of adrenal hormone at critical times during and after the operation. On the basis of experience gained in the preoperative and postoperative management of patients known to have Addison's disease, pituitary insufficiency, or hyperfunctioning adrenal cortical tumors and patients subjected to total adrenalectomy as treatment for hypertension or metastatic carcinoma, the following regimen may be proposed: 200 mg. of cortisone are given intramuscularly 48 hours, 24 hours, and 1 or 2 hours before operation. Cortisone given orally before operation may be of no advantage since its effects are of short duration and hence no steroid depot, such as is desired, is thereby created. If preoperative cortisone therapy is given, the dose of cortisone is gradually reduced after the operation. The rate of reduction of the dose and the duration of therapy after operation are determined by the condition of the patient. Usually treatment with cortisone is discontinued in three or four days. There seems to be no reason to fear untoward effects of such doses provided they are not given for long periods of time.

We believe that all patients who give a history of prior therapy with cortisone, regardless of whether they have been considered suitable subjects for preoperative or prophylactic treatment, should be followed postoperatively as though the surgeon expected to encounter adrenal cortical insufficiency. They should be closely observed, particularly during the first 24 hours after operation. Temperature, pulse, and blood pressure should probably be recorded at hourly intervals during this period.

Certain special precautions may, in some instances, enable patients to avoid difficulty. They should not be made to fast for an excessive period of time. If possible, the operation should be performed early in the morning rather than late in the day. Furthermore, patients should not be given excessive quantities of 5% solution of glucose and distilled water. The postoperative management of the water and electrolyte balance in patients with real or potential adrenal insufficiency is at best a difficult matter, but there seems to be no doubt that such patients do not tolerate excessive quantities of water. For this reason, glucose without sodium chloride solution should probably not be given. Also, such patients for reasons that are not understood, are sometimes adversely affected by morphine or its derivatives. Morphine or related substances, if given at all, should be used in small quantities; it would perhaps be best to use alternative types of narcotics.

If, in spite of all efforts, adrenal cortical insufficiency does occur, it appears that it is most likely to happen during the first 24 hours after operation. It is perhaps most likely to appear as a sudden circulatory collapse, fall in blood pressure, rise in pulse rate, and, perhaps, elevation of temperature. The patient may become unconscious rather quickly. Any of these symptoms should be regarded as indicating a serious emergency. The administration of an isotonic solution of sodium chloride or 5% glucose in an isotonic solution of sodium chloride should be started at once. If solutions of cortisone or hydrocortisone for intravenous use are available, they may be life-saving in such circumstances and should be given promptly. If solutions of steroids for intravenous use are not available, large quantities of aqueous adrenal extract should be administered both intramuscularly and intravenously (the latter by adding it to the sodium chloride solution administered intravenously). Four milligrams of norepinephrine added to the sodium chloride solution appears to aid in controlling circulatory collapse and extreme hypotension. Although it may have no immediate effect, 200 mg. of cortisone may be given intramuscularly, since it will ultimately become effective if the patient can be maintained during the first 24 hours by more rapidly acting preparations. If a patient is conscious and not nauseated or vomiting, 100 to 200 mg. of cortisone may be given orally. It is well to remember that while the activity of cortisone by this route is prompt, the duration of the activity is short (probably does not exceed eight hours).

In order to protect all patients from this surgical risk, the present state of knowledge may require that we treat many patients unnecessarily. This seems justifiable in order to protect the few who may undergo a serious hazard, particularly since there seems to be very little reason to fear that the measures proposed will be injurious even though they may be unnecessary. Until we have much more information than at present, it would be better to treat patients who do not require it than to withhold treatment and careful observation from those who do.

Finally, the fact that the use of cortisone, hydrocortisone, and corticotropin may introduce a new and serious hazard to future surgical treatment should provide physicians with an additional reason for making certain that the indications for which these drugs are used are reasonable and appropriate. There seems to be no reason, however, to regard this hazard as contraindicating the use of these drugs in those conditions in which they have real therapeutic advantages.

SUMMARY AND CONCLUSIONS

Cortisone may cause adrenal cortical atrophy and impair adrenal cortical function. These effects may outlast treatment for substantial intervals of time. They are regarded as the result of impaired production of endogenous corticotropin (ACTH) by the patient's pituitary gland. It seems reasonable to presume that the administration of exogenous corticotropin or hydrocortisone also produces this effect, and it is expected that treatment with these latter, like treatment with cortisone, would also be followed by adrenal suppression.

Two cases are presented in which acute postoperative adrenal cortical insufficiency was regarded as the cause of death. In both cases, anatomic changes in the adrenal glands were found that were considered the result of previous treatment with cortisone. Pathological studies in 46 cases in which cortisone treatment was used previously also indicated the ability of this substance to induce adrenal atrophy.

It is advisable to consider carefully the hazard of potential adrenal cortical insufficiency in any patient who requires surgical treatment and who has had previous treatment with cortisone, hydrocortisone, or corticotropin. Those patients in whom this hazard is considered serious should be treated prophylactically with cortisone given intramuscularly before operation. All patients who have had prior therapy with these hormones, whether treated prophylactically or not, should be observed with great care so as to avoid postoperative adrenal cortical insufficiency if possible and to treat it promptly in those few instances in which it is encountered.

GENITOURINARY COMPLICATIONS OF PELVIC FRACTURES

Donald E. Newland, M.D., Denver

This age of speed and great industrialization in which we are living has resulted in a considerable increase in the incidence of pelvic fractures. The frequency of associated urologic complications has risen in proportion. The effect of the automobile and the airplane on the frequency of these injuries, as well as their complications, is readily appreciated by references to the literature. Thirty-five years ago, only 4% of the cases of ruptured bladder were due to vehicular accidents.[1] Twenty years ago, Noland and Conwell [2] found that 35% of the cases of pelvic fracture were due to this cause, while only five years ago, Butt and Moore [3] reported that 73% of their cases were related to such accidents.

It has long been known that the cause of death, in those patients who had pelvic fractures complicated by injury to the urinary tract and who survived the initial injury, was urinary extravasation and infection. Although the wide use of plasma and whole blood has been extremely important in combating the initial shock and decreasing the early mortality, the advent of chemotherapy has undoubtedly been the prime factor in reducing the later mortality and morbidity from urologic complications. It has permitted wider use of the urethral catheter for diversion of the urine. It has reduced the severity of stricture formation in urethral injuries by controlling the infection usually associated with an indwelling catheter. It has prevented the systemic sepsis often accompanying these injuries and has permitted conservative treatment.

In spite of the merits of chemotherapy, the physician must not forget or disregard the primary surgical principles: (1) combat shock, (2) make an early and accurate diagnosis, (3) divert the urine, and (4) drain extravasated urine.[4] The adherence to these principles alone decreased the mortality from 78% in 1907 to 23% in 1942.[4]

In order to verify the value of chemotherapy in reducing the mortality and to determine the incidence of urologic complications, a study was made of the records of all cases of pelvic fracture during the period from 1947 to 1952 at Colorado General, Denver General, and St. Luke's hospitals. There was a total of 357 cases of pelvic fracture admitted to the three hospitals during this five year period (table 1). The incidence of urologic complications was 14%, 6.3%, and 3.8% in the respective institutions, with an average of 7.3%. The reported incidence of these complications in the literature varies widely and ranges from 7 to 40%.[3] The mortality rates in the group with no urologic complications were 6.7%,

13.5%, and 4.8% respectively, with an average of 8.3%. On the other hand, the mortality rates in the group with these complications were 25%, 33%, and 0, respectively, with an average of 19.3%.

It would appear from these figures that injury to the urinary tract more than doubled the mortality rate. An analysis of the case records showed, however, that in not a single case was death directly attributable to the urinary tract injury (table 2). All of those patients who died had extensive multiple injuries and lived only 4 to 24 hours; therefore, they can be eliminated in computing the mortality rate from urologic complications. There were no deaths in the group that survived the so-called initial injury period, and undoubtedly chemotherapy along with adequate, early surgery has done much to further reduce the once high mortality of these complications.

TABLE 1.—*Incidence and Outcome of Genitourinary Complications in Pelvic Fractures in Three Hospitals Over Period of Five Years*

Hospital	No. of Cases of Pelvic Fracture	No. of Cases With G.U. Complications	Deaths Without G.U. Complications	Deaths With G.U. Complications
Colorado General Hospital	86	12 (14%)	5 (6.7%)	3 (25%)
Denver General Hospital...	142	9 (6.3%)	18 (13.5%)	3 (33%)
St. Luke's Hospital.........	129	5 (3.8%)	6 (4.8%)	0
Totals	357	26 (7.3%)	29 (8.3%)	6 (19.3%)

Injuries to the bladder and urethra are the commonest urologic complications associated with fractures of the pelvis,[5] but occasionally damage to the ureters or kidneys may occur. Only those conditions involving the bladder and urethra will be discussed in this paper.

EXAMINATION OF PATIENT WITH FRACTURED PELVIS

The frequency of these complications demands that the urinary tract of every patient with a fractured pelvis be investigated to determine whether or not there is any damage to these organs. When one considers that the usual signs and symptoms may be misleading, it becomes apparent that a definite diagnostic procedure should be followed. For instance, a patient with a ruptured bladder may void clear urine, while a patient with only a contused bladder may void extremely bloody urine. Also, the pain and tenderness in the suprapubic area usually associated with bladder injuries may be due entirely to the bony injuries.

Accordingly, the following investigative plan is recommended. As soon as roentgenograms have been made confirming the diangosis of a fractured pelvis, a rectal examination should be done. If there has been complete severance of the urethra at its junction with the prostate, the normal outlines of the gland will not be palpable; in fact, one will feel only a soft, boggy mass in the usual location of the prostate as the gland is retracted anteriorly and superiorly. The remaining space is filled by a large hematoma. If this examination reveals no abnormality or if confirmation of a diagnosis is desired, then an attempt should be made to pass a soft rubber catheter. This, of course, should be done with gentleness and under aseptic conditions. If the catheter passes easily, it is very important that it be left in place until the physician is completely satisfied that there is no injury to the urethra or bladder.

The facility with which the initial catheterization is done and the fact that a clear urine is obtained may lead the physician to believe that there has been no damage to the urethra; therefore, the catheter is removed, and the physician later finds that it cannot be reintroduced. It is then necessary to do a suprapubic cystostomy that might have been avoided if the catheter had been left in place.

After insertion of the catheter, 150 cc. of a 10% solution of an opaque medium, such as that used in intravenous pyelography, should be injected. This medium is recommended because it is relatively innocuous and will be absorbed or drained if surgery is performed. It is certainly preferable to oily types of medium that remain in the tissues for long periods or to sodium iodide that has certain irritating properties. A simple anterior-posterior film usually shows the presence or absence of rupture, although an additional oblique view may be helpful.

The injection and withdrawal of a measured amount of isotonic sodium chloride solution is to be condemned. If the bladder rent is small or if it is large but occluded by a piece of bowel, one may withdraw the same amount of fluid as injected even if the bladder is ruptured. Also, the catheter may become occluded by a blood clot so that less fluid is withdrawn than injected, even though the bladder is intact.

Use of the catheter and the retrograde cystogram is not accepted by all urologists because of the danger of increasing extravasation and spreading infection. I have found, however, that its main advantage has been to give almost infallible information immediately without any apparent ill effects. A cystogram may be secured by injection of dye intravenously. The main disadvantage to this method is that the patient is in from moderate to severe shock at the time the information is desired; therefore, the procedure has little value until shock has subsided and renal function has improved. Cystoscopy as a diagnostic procedure should be done only as a last resort, after all other diagnostic measures have failed to demonstrate a suspected injury. I have seen only two cases in which all other methods failed to disclose a ruptured bladder; yet such a lesion was found by cystoscopy.

TABLE 2.—*Causes of Death in Patients with Genitourinary Complications of Pelvic Fractures*

Causes of Death in Patients with Pelvic Fractures and Genitourinary Complications	Genitourinary Complications Present
1. Arteriosclerotic heart disease with recent and old infarction	Hematoma of bladder
2. Fractured pelvis, ankle, and vertebrae; died before full extent of injuries was determined	Thought to have a ruptured bladder
3. Subdural hematoma and fractured left leg and pelvis	Ruptured membranous urethra
4. Fractured ribs with hemothorax and lacerated liver with hemoperitoneum	Urethral bleeding
5. Acute pulmonary edema and fractured ribs and pelvis	Ruptured bladder
6. Ruptured spleen	Perivesical hemorrhage

DIAGNOSIS AND TREATMENT OF INJURY

The diagnosis of injuries to the urethra is usually not too difficult. The appearance of a slight or profuse amount of blood at the meatus before the patient has attempted to void means damage to the urethra at some point distal to the triangular ligament. If the injury is above this point, then there is no bleeding at the meatus, unless the patient has attempted to void.

---

[5] McCague, E. J.: Factors Influencing Mortality and Morbidity in the Intrapelvic Ruptures of the Urethra and Bladder, Tr. Am. A. Genito-Urin. Surgeons (1942) 35: 307-316, 1943.

The extent of the injury can usually be determined by the introduction of a soft rubber catheter. If there is complete severance of the canal, then the two ends usually separate, and since they are at different levels the catheter cannot be passed beyond this point. With only partial laceration, the catheter may pass easily into the bladder. If difficulty is encountered in passing an ordinary straight or Robinson catheter, the use of a coudé or Tiemann catheter may permit passage because the curved tip tends to follow the anterior wall of the urethra, which is usually intact if there is only partial severance. Occasionally, catheterization can be accomplished under anesthesia in cases in which it cannot be done otherwise, but, again, gentle manipulation is essential to avoid increasing the damage already present in the urethra.

The importance of catheterization is stressed because, if it can be accomplished, the catheter, if left in place, will provide urinary drainage as well as a splint on which the urethra can repair itself, and further surgery may not be necessary. Of course, infection may develop later in the traumatized area and may require incision and drainage.

In the case of complete severance of the urethra, catheterization is usually impossible for the reasons already stated; therefore, it is necessary to perform a suprapubic cystostomy for diversion of the urine. At cystostomy, it may be possible, with the use of Davis interlocking sounds, to bring the two severed ends together and to introduce a catheter through the urethra as a splint. If it is impossible to bring the two ends of the urethra together in this way, then open surgical repair is usually not advisable at the time of the injury because (1) a perineal incision is necessary, but the patient's poor condition often precludes this additional surgery; (2) the required lithotomy position is not advisable, because of the injuries to the pelvis; and (3) the added factor of possible hemorrhage into the perineal tissues makes dissection and identification of structures difficult. The optimum time for this surgery will vary with each case and will depend on associated injuries, patient's general condition, and presence or absence of infection. It certainly should not be delayed for several months, as the formation of dense scar tissue then makes the repair extremely difficult.

If the rupture involves the membranous urethra superior to the triangular ligament, then surgery is usually necessary because the most frequent injury to this portion is complete severance. This condition demands suprapubic exploration to reestablish continuity of the urethra as well as to drain extravasated urine. Since it is impossible to suture the prostatic urethra to the membranous portion, the Foley catheter has become an invaluable aid in treatment.[6] At the time of surgery, a Foley catheter is inserted into the meatus and through the anterior urethra. The tip of the catheter can be palpated as it emerges from the severed membranous urethra. It may then be difficult or impossible to introduce the tip into the prostatic urethra. This difficulty can be overcome by opening the bladder and introducing a second catheter from above. When it appears at the apex of the prostate, it is grasped and sutured to the Foley catheter. Traction on the upper catheter will draw the Foley through the prostatic urethra and into the bladder. After this maneuver, the Foley catheter bag is inflated, and the bladder opening is sutured. When the patient has been returned to bed, traction is placed on the catheter thus approximating the two ends of the urethra until healing can take place. This traction can be applied by various means, but it is believed that the use of an extension cord, with an attached weight, over a pulley at the foot of the bed is preferable. This gives a constant pull regardless of the position of the patient in bed. Usually a one-half to a one pound (226.8 to 463.59 gm.) weight is sufficient to accomplish the necessary approximation.

The end-result of most injuries to the urethra is the formation of a so-called traumatic stricture; therefore, all patients with urethral injuries should receive urethral dilatations for an indefinite period. Some may require this treatment for as long as they live. Uhle [7] reports that stricture formation is severer in the external urethra than in the membranous urethra above the triangular ligament, and this has proved true in my experience.

COMMENT

The diagnosis of bladder injuries has been discussed with the investigative procedure to be followed in fractures of the pelvis. Such injuries vary from contusions, which require no treatment other than catheter drainage, to lacerations, which require surgical therapy. The procedure at the time of surgery depends on the location and size of the laceration and on whether the lesion is extraperitoneal or intraperitoneal. If, however, a rupture is suspected but cannot be verified, it is preferable to do exploratory surgery than to permit such an injury to go untreated. Exploration is made through a suprapubic incision. In the common extraperitoneal rupture, blood and urine are encountered as soon as the perivesical space is entered. If the rupture is intraperitoneal, then there is no urine in this area, but blood may be present as a result of the pelvic fractures.

In all doubtful cases, the peritoneum should be opened to determine the presence of blood and urine in this cavity. If either is found, the laceration should be located and sutured. Even if an extraperitoneal rupture is found, it is often advisable to open the peritoneum so that associated injuries to other abdominal organs are not overlooked.

Small extraperitoneal lacerations not readily accessible for suturing usually require no more than drainage of the perivesical spaces. These lacerations approximate and heal spontaneously, if the bladder is kept empty. This can be accomplished with an indwelling urethral catheter. The use of a de Pezzer catheter for suprapubic drainage of the urine is usually not necessary in this type of case but may be used if desired. The most important factor is drainage of the extravasated urine.

REPORT OF CASES

CASE 1.—A white man, 45 years of age, was admitted to the hospital on Nov. 3, 1949, approximately 30 minutes after a large, heavy piece of refrigeration equipment fell on him and crushed his pelvis. Initial examination revealed him to be in extreme shock, with rapid, thready pulse and blood pressure of 40/0 mm. Hg. Plasma was administered, and supportive therapy was instituted immediately. Films of the pelvis revealed complete fractures with fragmentation of the pubic rami on both sides and a fracture of the neck of the left femur. A soft rubber catheter was passed through the urethra, and only a small amount of bloody fluid was obtained. Injection of 150 cc. of 10% iodopyracet (Diodrast) solution was made through the catheter. A film revealed the dye to be extravasated along the lateral wall of the pelvis and nothing simulating a normal bladder outline (fig. 1).

Even though it was evident that this patient's bladder was ruptured, nothing could be done surgically because of the patient's precarious condition. During the next 18 hours, the patient received two units of plasma and 3,000 cc. of whole blood. At the end of this period, it was believed that improvement was sufficient to allow surgical drainage and repair of the ruptured bladder.

On exploration through a suprapubic incision, a large amount of bloody fluid was encountered in the area around the bladder. Since the possibility of associated injury to intraperitoneal viscera had not been excluded, the peritoneum was opened. It was closed when no blood or fluid was found. Further exploration in the extraperitoneal pelvic area showed that the prostate was torn free of its fascial attachments and that the membranous urethra was completely severed. In addition, the bladder was almost completely avulsed from the gland; it was still joined only at the trigone (fig. 2). During this procedure, a number of free spicules of bone were removed from the pelvic cavity. The repair was accomplished by passing a Foley catheter through the external and prostatic portions of the urethra into the bladder. The bag was inflated to permit traction. No attempt was made to suture the severed membranous urethra. The bladder was sutured to the superior surface of the prostate gland.

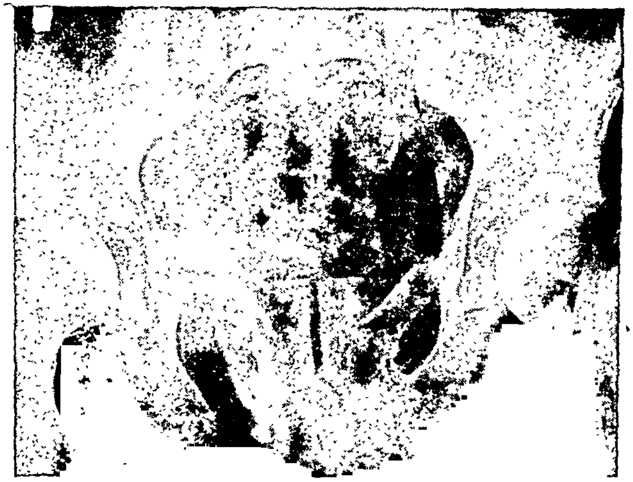

Fig. 1.—Generalized pelvic extravasation of dye with no semblance of bladder outline.

When the patient was returned to bed, tension was applied to the Foley catheter by running a cord from the catheter over a pulley at the foot of the bed and suspending a one-half pound (226.8 gm.) weight at the end of the cord. This constant pull served to approximate the torn membranous urethra until healing could take place. The patient made a slow recovery that was complicated by bilateral bronchopneumonia. After removal of the urethral catheter on the 18th postoperative day, the patient was able to void freely, with complete urinary control. Since then, it has been possible to maintain an urethral caliber of no. 24 French catheter with only intermittent dilatations.

This case demonstrates not only the likelihood of repair but the prospect of obtaining a good functional result even in the severest bladder and urethral injuries. It also reemphasizes the value of the Foley catheter as a traction agent in reapproximation of the urethra in cases in which suturing is impossible or not feasible.

CASE 2.—A 25-year-old white man was admitted to the hospital on Oct. 29, 1949, about eight hours after injury. He stated that he was riding on the fender of a dump truck when he slipped and fell to the ground and the back wheels of the truck passed over his pelvis.

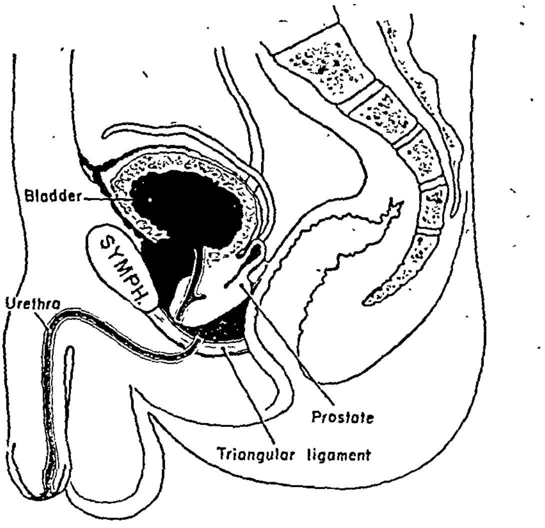

Fig. 2.—Schematic drawing of injuries to bladder and urethra

On admission, the patient was in mild shock, so measures were taken to correct that condition. Films of the pelvis revealed multiple fractures. A Foley catheter was introduced, and 400 cc. of grossly clear urine was obtained; however, microscopic examination revealed that it contained many red blood cells. Urologic consultation was not requested since it was believed that the patient had a contused rather than a ruptured bladder because of the large amount of urine obtained at the initial catheterization and because the urine was not grossly bloody.

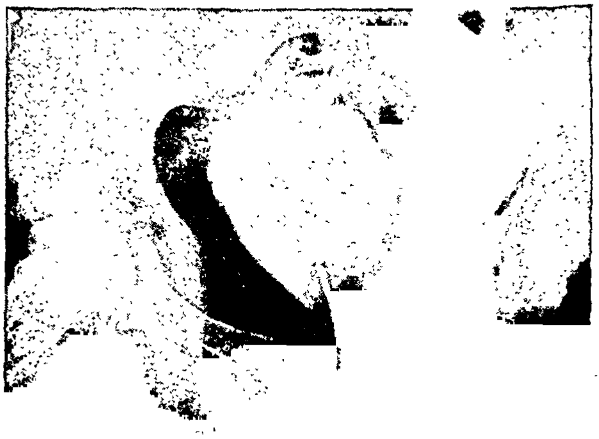

Fig. 3.—Cystogram showing small amount of dye extravasated in region of membranous urethra.

I first saw the man on Oct. 31, 1949, two days after his injury, because the urine draining from the indwelling catheter had become increasingly bloody. Examination revealed the patient to be acutely ill, with a fever of 102 F. There was some tenderness and slight rigidity of the lower abdomen; this was more pronounced on the right side. Palpation of the scrotum disclosed generalized tenderness and induration of the entire sac. Auscultation of the chest revealed numerous rales throughout both lungs. A cystogram showed the general bladder outline to be normal but extravasation of the dye low on the right side of the pelvis (fig. 3). These findings, together with the indurated scrotum, indicated that patient had a tear in the membranous urethra extending both above and below the triangular ligament.

It was decided to treat this patient conservatively because (1) his general condition was not good, (2) he had evidence of a developing pneumonia, and (3) as he had had an indwelling catheter since his initial examination, the extravasation of urine had been held to a minimum. Pneumonia with atelectasis of the right upper lobe did develop, but the patient recovered from this as well as from his other injuries. The urologic complications cleared without treatment other than catheter drainage.

The course of treatment followed in this case is certainly not recommended except in the rare instance in which it is believed that the shock of a surgical procedure may do the patient more harm than good. It does emphasize, however, what can be accomplished by diversion of the urine and chemotherapy, if the occasion demands. It also demonstrates the value of leaving the catheter inserted until the condition of the urinary tract is fully determined.

Case 3.—A white boy, 2 years of age, was struck by an automobile about 10:30 a. m. on Aug. 10, 1949. He was given emergency treatment at the Denver General Hospital and then transferred to Porter Hospital. Roentgenograms revealed fractures of the left clavicle, of the fourth, sixth, seventh, and eighth ribs on the left side, and of both ascending pubic rami.

The boy was treated for severe shock, but injury to the bladder was not suspected until eight hours later, when he voided 15 cc. of bloody urine. Urologic consultation was requested, and an intravenous pyelogram was done, since the patient was no longer in shock. This pyelogram disclosed extravasation of the dye to the right of the normal bladder outline (fig. 4). He was immediately taken to surgery where exploration disclosed a large amount of bloody urine in both lateral extravesical spaces. A bluish discoloration was noted under the peritoneum, and, on opening the peritoneum, free blood was encountered. Further exploration disclosed transverse laceration of the spleen. The patient's condition was so poor that splenectomy was not considered; the laceration was packed with oxidized cellulose (Hemo-Pak) and the peritoneum closed. A de Pezzer catheter was inserted in the bladder, and no attempt was made to close the laceration. The patient had a very stormy course for the first four days and then improved rapidly. The catheter was removed on the 10th day, and the suprapubic sinus healed spontaneously. He was discharged on the 14th hospital day for convalescent care at home.

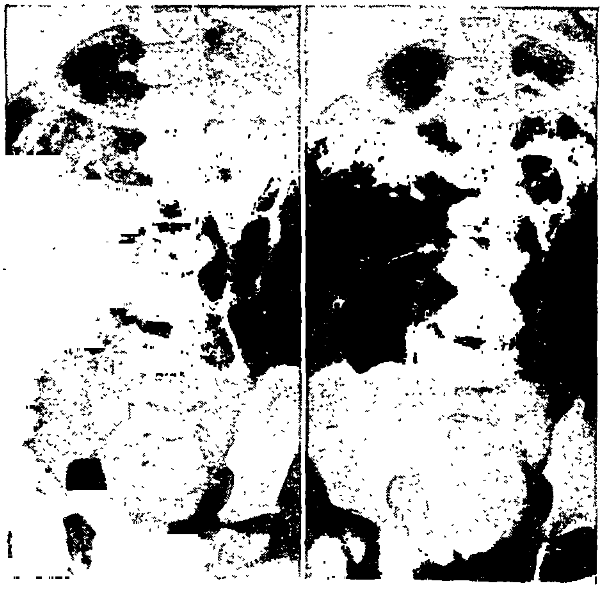

Fig. 4.—Intravenous pyelograms revealing dye extravasated along right side of bladder.

This case emphasizes the importance of intraperitoneal exploration at the time of surgery even though an extraperitoneal rupture of the bladder is found. It also demonstrates the value of intravenous pyelography as a diagnostic agent.

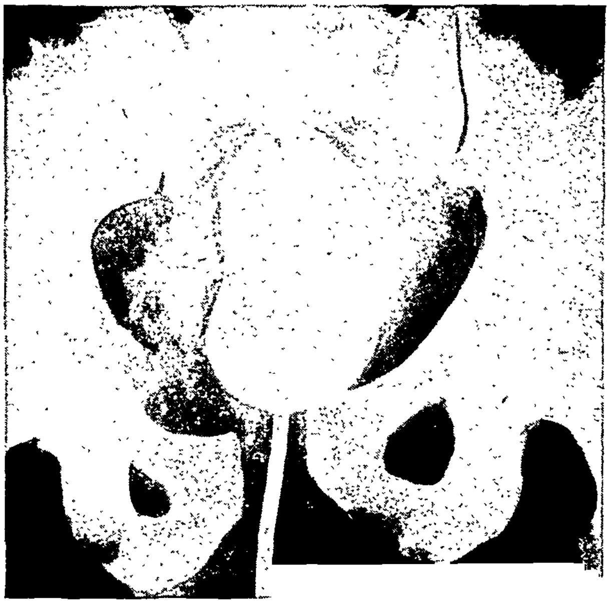

Fig. 5.—Cystogram showing extravasation of dye with bilateral vesical tears.

Case 4.—A white man, 31 years old, was admitted to the hospital on Nov. 19, 1947, approximately eight hours after a large log had rolled over his pelvis. His only complaint was pain in the suprapubic area; examination disclosed marked tenderness in this area. There was no evidence of shock. Roentgenograms revealed separation of the symphysis, with displacement of the sacroiliac joints. A soft rubber catheter was passed easily, and 375 cc. of slightly blood-tinged urine was obtained. Films made after injection of the dye showed a bilateral extravasation (fig. 5). Repair of the lacerations was done through a suprapubic incision, and Penrose drains were left in both lateral perivesical spaces. The bladder was drained with an indwelling urethral catheter. After this procedure, the patient made an uneventful recovery.

This case emphasizes the fact that there can be extensive injury to the bladder,[8] even though a large amount of relatively clear urine is obtained on catheterization.

Case 5.—A Spanish-American man, 38 years of age, was working on the roof of a building when he slipped and fell approximately six feet and landed astride a 2 by 8 in. joist. When he was admitted to the hospital on Sept. 16, 1952, about two hours after injury, he complained of pain in the perineum and a constant desire to void but inability to do so. Examination disclosed no evidence of shock, although there was profuse bleeding from the urethral meatus. There was a large hematoma involving the perineum and the inner aspect of the left thigh. A fracture of the left descending pubic ramus was revealed roentgenologically. It was evident that this patient suffered severe trauma to the urethra, with partial or complete rupture. In order to determine the extent of the injury, attempts were made to pass straight and coudé catheters, but both were obstructed in the bulbous portion of the urethra. The patient was taken to surgery where preparation had been made to do a suprapubic exploration, if another attempted catheterization was unsuccessful. A spinal anesthetic was administered, and gentle attempts were again made to pass a catheter. A no. 16 coudé soft rubber catheter was inserted rather readily in the bladder and taped in place. The indwelling catheter was removed on the 10th day; after that, the patient was able to void freely with normal control. By this time the hematomas in the perineum and on the thigh had been almost completely absorbed and did not require incision and drainage.

---

[8] Prather, G. C., and Kaiser, T. F.: The Bladder in Fracture of the Bony Pelvis: The Significance of a "Tear Drop Bladder" as Shown by Cystogram, J. Urol. 63: 1019-1030, 1950.

This case demonstrates the advantage of the use of anesthesia in some instances of urethral injury in which catheterization is unsuccessful otherwise. It also emphasizes the value of chemotherapy in the treatment of these cases. This patient would have undoubtedly had a stormy course with infection around the catheter and in the areas of hematoma if it had not been for these drugs.

SUMMARY

The frequency of urinary tract injuries associated with fractures of the pelvis demands that every such case be investigated for this complication. A suggested diagnostic procedure is outlined. An analysis of 357 cases of pelvic fracture shows that genitourinary complications do not increase the mortality rate of these injuries. Individual case histories illustrate the manner of treating these complications and the role of chemotherapy in reducing mortality and morbidity.

RESPIRATORY DISORDERS AMONG WELDERS

Robert Charr, M.D., Philadelphia

Welding is a method of fusing metals in which an electric arc is formed between a metal electrode and the material to be welded. During the process the electrode melts and forms a bond. The electrode is made of the same metal as that being welded. The commonly used electrode is steel, which, on heating, gives off fumes containing particles of iron oxide measuring 0.5 millimicron in diameter. The electrodes usually are coated, and the coating, on heating, forms a gaseous cone that prevents the molten metal from evaporating too readily. The composition of the coating varies, but fluorides, silicates, borates, aluminum, cadmium, and chromium are found in different products. Of these, fluorides and cadmium are the most irritating, and there is reason to believe chromium may be carcinogenic.

The fumes of welding, particularly those arising from fluorides, cadmium, and chromium, are irritating to the mucosa of the respiratory tract. Cough, expectoration, chest pain, sense of oppression about the thorax, and hemoptysis with fever known as metal fume fever may develop as an acute reaction. These symptoms subside on avoidance of exposure to the fumes. If the exposure is continued, roentgenologic changes in the lungs, such as exaggerated linear shadows in some and nodulation in others, may occur. The increased linear markings and the nodulation seen in roentgenograms apparently are due to deposition of ferrous particles within the perivascular and peribronchial lymphatics. It is generally believed that these pulmonary changes are not disabling. In occasional instances, however, they may be harmful.

REPORT OF CASES

CASE 1.—W. M., a 61-year-old man, had done welding for 12 years, using only steel electrodes. In 1949, dyspnea became so pronounced that it was difficult for him to continue working. In addition to dyspnea he had cough, expectoration, and pain in his chest. In 1952, it was necessary for him to discontinue working. Physical examination showed an undernourished man with cyanosis and respiratory rate of 40 per minute. The chest was rounded and showed the signs of emphysema. A chest roentgenogram suggested diffuse pulmonary fibrosis throughout both lungs, characterized by exaggeration of the lung markings without definite evidence of nodulations (fig. 1). The lower third of each lung appeared emphysematous. The heart was long and narrow, and the diaphragm was depressed on both sides.

CASE 2.—C. D., a 50-year-old man had been a welder for 24 years. His complaints were dyspnea, cough, expectoration and sensation of oppression in his chest. The principal findings were pronounced cyanosis and clubbed fingers. The chest was rounded, and there was very little expansion of the chest on inspiration. Throughout the lungs were sonorous rales. The respiratory rate at rest was about 40 per minute. A chest roentgenogram showed exaggeration of the lung markings in the lower half of each lung, particularly about the hilar areas. In addition, there was some fibrosis in the right upper lobe in the first interspace. In the right lower lobe near the heart were scattered fine deposits. The diaphragm was depressed on both sides.

CASE 3.—H. C., a 50-year-old man, had been a welder for six years, working mostly with steel. At times he worked with galvanized metal, which contains lead. His chief complaints were shortness of breath on exertion, cough, expectoration, and constant sensation of oppression in his chest. The roentgenogram (fig. 2) showed exaggerated tissue markings throughout both lungs, particularly about the hilar regions. In addition, there were fine nodular deposits in the lower half of each lung. Although the patient was ambulant, he had constant substernal discomfort. After he had done no welding for six months, he had another roentgenologic examination. Some of the changes noted earlier had disappeared.

These three men found it difficult to continue working as welders. Although it was not possible to carry out accurate tests such as pulmonary function studies and biopsies of the pulmonary tissues, there was no doubt as to the severity of their symptoms. It is true that the symptoms are those of emphysema, not necessarily related to welding; therefore, one may question the validity of incriminating their occupation.

CASE 4.—J. G., a 34-year-old man, had been a welder for some years. A roentgenogram (fig. 3) showed diffuse nodular deposits throughout both lungs, almost typical of changes seen in the second stage of silicosis.

CASE 5.—E. G., a 59-year-old man, had been a welder for a number of years. The roentgenogram showed exaggerated pulmonary markings throughout both lungs, with scattered fine nodulation on both sides.

These two men, despite lung changes and other related symptoms, were able to continue working, although under some difficulty.

Presented at the Regional Meeting of the American College of Chest Physicians, Philadelphia, May 7, 1953.

From Jefferson Medical College, Philadelphia Tuberculosis and Health Association, and Pennsylvania Hospital.

Case 6.—G. D., a 35-year-old man, had been a welder for over 15 years, working chiefly in confined spaces such as submarine chambers. Most of the time he used steel electrodes. His chief complaints were cough, expectoration, pain in the chest, and shortness of breath on exertion. Physical examination showed cyanosis of the lips and fingernails. The chest was normal in shape, but expansion was poor on both sides, with dullness over the upper lobe of each lung. Over the entire chest the breath sounds were exaggerated, with occasional musical rales over the upper lobes. The roentgenogram showed considerable fibrosis in both lungs, particularly in the upper lobes. Sputum examinations were positive for acid-fast organisms. After six months of complete bed rest with antimicrobial therapy, the patient improved sufficiently to return to work. At present he is symptom free aside from persistent substernal discomfort and dyspnea on exertion.

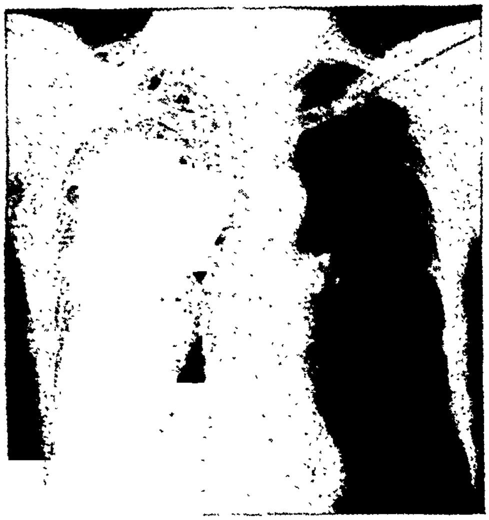

Fig. 1 (case 1).—Roentgenogram showing emphysema and possible pulmonary fibrosis.

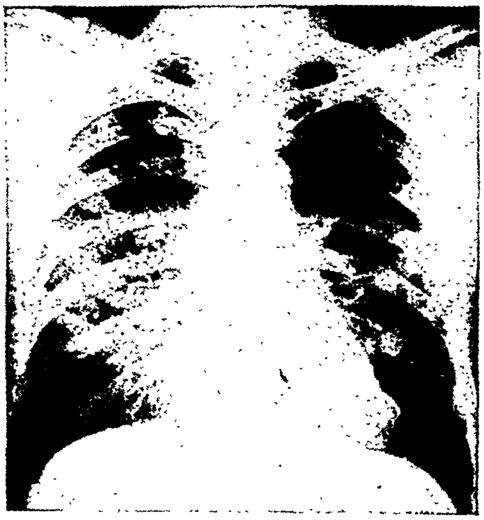

Fig. 2 (case 3).—Roentgenogram showing diffuse changes in the middle third of each lung.

Case 7.—A. G., a 45-year-old man, had been a welder over 16 years. Most of the time he used steel electrodes, but on several occasions he used chrome electrodes, the fumes of which made him extremely uncomfortable. The discomfort was entirely due to choking sensation, difficulty in breathing, and substernal pain. In 1942 he was found to have acute tuberculosis involving the left upper lobe with cavitation. Thoracoplasty was done. During the past seven years he has been working full time as a welder without relapse.

Tuberculosis does not appear to be a frequent complication of pulmonary changes in welders, although there are no large statistical studies on this subject. The clinical course of tuberculosis in welders appears about the same as that in the general population.

COMMENT

Doig and McLaughlin [1] and Enzer and Sanders [2] described pulmonary changes seen in chest roentgenograms of welders. They pointed out that the changes were indistinguishable from those in silicosis; however, in persons with silicosis the changes are permanent, but in welders, on cessation of exposure, the changes may disappear as noted in case 3.

Iron dusts are generally considered inert when inhaled into the lungs. The particles are deposited in the lymphoid tissues and do not cause fibrosis or serious tissue changes.

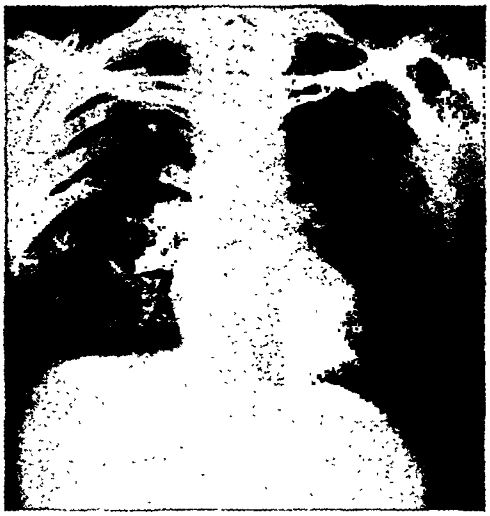

Fig. 3 (case 4).—Roentgenogram showing nodulation in both lungs.

Roentgenologic lung changes have been produced experimentally in animals, but the tissues showed no fibrosis or other reaction. Enzer [3] did a post mortem of the lungs of a welder and found deposits of particles in the perivascular and peribronchial lymphatic spaces but found no fibrosis, as in silicosis.

There is no functional impairment of the lungs with such iron deposits, either in appearance of clinical symptoms or in susceptibility of the patient to complicating infections. The condition is not crippling as is silicosis. Once the exposure is stopped, the disease does not progress. Many welders have cough and expectoration but no dyspnea. They have good chest expansion and good tolerance for exercise. In short, inhalation of welding fumes is not seriously incapacitating. Enzer [3] had agreed that inhalation of iron dust produced by welding operations did not produce fibrosis but recently, after examining two disabled welders, was less inclined to accept the idea that pulmonary disability never results.

[3] Enzer, N.: Personal communication to the author.

Doig and Duguid [4] studied 240 welders, and their conclusion was that most of the welders had some irritation of the throat as well as the larynx. The incidence of nasal catarrah and frequent colds was higher among welders than in the general population. Cough, expectoration, and discomfort in the chest, together with the physical signs of emphysema, were common. In a group of welders with a long duration of employment, particularly those who had worked in confined places, abnormal roentgenologic changes that could not be differentiated from silicosis were frequently noted. It was found, however, that on cessation of exposure to welding fumes these changes disappeared, which suggests that the iron particles were inert and easily removed by the phagocytes. Among these 240 welders, the incidence of tuberculosis and other serious pulmonary diseases was not greater than would be expected in the general population. Doig and Duguid concluded that inhalation of welding fumes, particularly fumes containing iron oxide particles, was not disabling but could cause acute respiratory symptoms that subside on cessation of exposure. Commenting on cases 1, 2, and 3, Doig [5] suggested that disability might not be due entirely to iron oxide dusts but perhaps to inhalation of fumes arising from the coatings of the electrodes, which may contain noxious material.

According to Carnahan,[6] in the 1950 U. S. census there were about 276,000 persons in the United States engaged in electric arc welding, almost 10,000 of whom were women. The incidence of serious siderosis in welders is low, but it does exist. Clinical and physiological studies as well as histological examinations of pulmonary tissues in suspected cases may clarify the problem. The question of disability is important not only from the viewpoint of the patient but from the standpoint of occupational diseases.

SUMMARY

The clinical and roentgenologic findings in seven welders with respiratory disorders are described. In three the symptoms were sufficiently serious to necessitate a change of occupation. Biopsy of the pulmonary tissues and studies of pulmonary function may aid the study of this condition.

INTERDEPENDENCE OF THE MEDICAL PROFESSION AND THE PHARMACEUTICAL INDUSTRY

Elmer L. Sevringhaus, M.D., Nutley, N. J.

Let us first admit two obvious facts: the physician depends on pharmaceutical manufacturers to produce useful and dependable drugs, and the manufacturers depend on physicians to prescribe and use drugs whenever a therapeutic advantage may be anticipated. Implicit in these statements is a surprising variety of topics for discussion.

Let us turn back to the year 1724. I choose this date because it appears on the title page of a small volume I cherish, entitled "Mr. Boyle's Receipts." The same John Boyle, whose statement of the interrelationship between pressure and volume of gases is the familiar Boyle's Law, was a therapeutically minded chemist. He assembled numerous directions for preparing remedies and then solicited trials of their efficacy by the physicians of his day. Remedies that gained sufficient approval were published in the volume referred to above. Following are a few examples of what the physician could expect from his local pharmaceutical manufacturer in 1724.

> LXII. *An uncommon, but try'd Remedy for* Cholicks *(without much matter) and good in Fits of the Mother.*—Take good Ginger dry, and instead of powdering it, cut it into as thin Slices as you easily can: With these fill a Tobacco-Pipe, and take the Smoak as you would that of Tobacco. Do this twice, thrice, or 4 Times a day, but especially at Bed-time, and in the Morning.
>
> LXIII. *An excellent Medicine for* Convulsive Cholicks.—Take of the Volatile Salt of Pidgeons Dung 2 or 3 Grains, or somewhat more (not exceeding 5 or 6 in all) mix these with a Scruple or half a Dram of the fame Dung crude, but well and slowly dry'd, and finely powder'd. Give this Mixture for 1 Dose in some Spoonfuls of any convenient Vehicle.
>
> CXIII. *An uncommon, but experienc'd Remedy for* Dysenterical Fluxes.—Take the Bone of the Thigh of a hang'd Man (perhaps another may serve, but this was still made Use of) calcine it to whiteness, and having purg'd the Patient with an Antimonial Medicine, give him 1 Dram of this white Powder for 1 Dose, in some good Cordial, whether Conserve or Liquor.
>
> CXLI. *An experienc'd Medicine for the Pains of the* Hæmorrhoids.—Take the Sole of an Old Shoe, worn by some Man that walks much, cut it in Pieces, and burn it, not to white or grey Ashes, but to a fryable and tender Coal; reduce this to impalpable Powder, and then with a sufficient quantity of unsalted Lard, make it into an Unguent.

A century later a chemical discovery was made that led ultimately to replacement of the human-bone, shoe leather, pigeon's dung, and even the ginger by synthetic chemicals. The discovery by Wöhler, in 1828, of the synthesis of urea from inorganic materials was the initial step in the enormous development of organic chemical synthesis. No longer do we use natural oil of wintergreen; we prescribe one of a number of synthetic derivatives of salicylic acid. For treatment of gonorrhea we may choose between synthetic sulfonamides or penicillin. Although the antibiotics may be considered products of decomposing organic matter, they are more properly thought of as pure substances manufactured by skillfully guided biological processes. The skillful supervision of these processes and the subsequent purification that makes the antibiotics so dependably useful in therapy are among the facilities that modern pharmaceutical manufacturers provide. It is not necessary to enumerate further examples of the application of chemical, physical, and biological science to the manufacture of drugs. Modern

Dr. Sevringhaus is Director of Clinical Research for Hoffmann-LaRoche Inc., Nutley, N. J.

Read in the General Scientific Meetings at the 102nd Annual Session of the American Medical Association, New York, June 1, 1953.

drugs are identified chemical compounds, which now dominate our pharmacopoeias and compendiums of new drugs.

DEVELOPMENT OF NEW DRUGS

Where have new drugs originated? Until 30 years ago the laboratories of the universities were almost the only places where such chemical discoveries or inventions were made. Within the last three decades we have witnessed the rise of a new type of research laboratory, housed in and supported by the various and independent units of the modern pharmaceutical industry. The majority of new drugs are now coming from these industrial laboratories. We may ask why a function developed by the universities has been transferred so largely to industrial organizations.

Specialization of scientific and technical skills, although frequently deplored, has been essential to much of this development. Along with specialization there is an indispensable collaboration among chemist, pharmacologist, bacteriologist, pathologist, physicist, and engineer. But we cannot stop here. Until the products of these collaborating workers have been evaluated critically by physicians who use the chemicals as drugs to treat illness, they are not ready for general use by the medical profession. Here we find an essential role for physicians.

The last two decades have seen the development of at least two specialized services by physicians that are indispensable to the manufacturer of pharmaceuticals. The pharmacologist must determine the characteristics of biological activity of new compounds, including toxicity and undesirable actions. Without the use of laboratory animal testing the pharmaceutical industry would be impotent. This type of study, beginning with mice and rats, is never complete until human pharmacology is included. This latter step provides the first of the opportunities for the staff in clinical investigation. These physicians occasionally have hospital staff positions that enable them to make clinical observations at first hand. More often they establish arrangements for studies of new compounds with experienced physicians who have no direct connection with the pharmaceutical firm.

The medical profession in general and the public usually are not familiar with the work of physicians in the pharmaceutical industry or the special qualifications they must have. These men usually are qualified in clinical medicine and in addition have a background in clinical research. Such training becomes of greater value as experience is gained in the special kind of clinical investigation required in the drug industry. These men bridge the gap between the laboratory and the clinic and must be capable of evaluating animal results with a new compound in terms of its first human trial. The first human application is often accomplished under the personal supervision of the physician in industry. Thereafter, promising compounds are widely placed with other clinical investigators to be tested further before general use of them can be recommended. Obviously, years of contact with the medical profession are necessary to build up clinical connections of such quantity and quality that adequate evaluation of new drugs can be completed without delay. The qualifications for men who occupy posts in clinical research in the pharmaceutical industry are: a doctor's degree in medicine; internship and residency; clinical experience; research training, preclinical or clinical; a high standard of scientific ethics; an imaginative concept of drug therapy; ability to write and to speak; liking for people and travel; and willingness to consider opinions of others.

On these physicians rest the varied responsibilities concerning experimentation on human beings. An extensive discussion of this problem was recently published in *Science*.[1] I need not take time to stress the obvious features of safety of the patient, correct determination of dose, and a follow-up for cumulative or chronic effects as well as for immediate results from use of a new drug. Attention should be directed to a more elusive question, that of the adequacy of evidence upon which to establish the efficacy of any new therapy.

QUALIFICATIONS FOR APPROVAL

The intense competition among pharmaceutical manufacturers makes it certain that ultimately only the superior products will be prescribed by physicians. But much time and valuable advantage to health may be lost if use in practical therapy must achieve these ends. Consequently there is rapidly growing emphasis on objective means for diagnosis and on estimation of improvement. Since both of these methods are often difficult to carry out in clinical medicine, two other devices are invoked: statistical treatment of data from observations on many patients who receive a new drug and the "blind test." This latter means that neither physician nor patient knows when the drug in question is being given or when an accepted drug or an inactive tablet has been substituted for comparison. It is obvious that safe and competent planning of such clinical research is of vital importance to both manufacturers and physicians.

The need for these rigidly controlled studies has become increasingly evident as we have progressed from producing drugs that are the traditional "specifics" to those that alleviate symptoms or modify the course of disease without effecting a cure. To the psychologist or psychiatrist this need for controls is logical. But to the physician, whose therapy is supposedly directed mainly toward objective changes, we must continually put the question, "How sure are you that the symptomatic response was caused by the drug and was not merely a coincidence?" This type of question is not popular with most physicians, but unless we continue to ask it we shall repeat the error of misplacing our faith in worthless remedies. Every experienced physician realizes how pain may be increased or abated, even brought about or abolished, at times, by changes of mood or attention. Does this make pain any less real? Not to the sufferer. We must recognize the fact that pain is a subjective phenomenon. No one has been able to measure pain itself. But by use of "blind tests" involving new drugs, accepted drugs, and completely inactive substitutes, and with statistical study of the results, dependable conclusions can be drawn. These may include the type of pain relieved, the probable usefulness of a new compound, and the recommended dosage. "Blind testing" must also be relied on for the numerous remedies proposed for relief of all types of functional disorders.

[1] Shimkin, M. B.; Guttentag, O. E.; Kidd, A. M., and Johnson, W. H.: The Problem of Experimentation on Human Beings, Science **117**:205-215 (Feb. 27) 1953.

Physicians who use new drugs with critical eyes can help determine a great variety of unexpected or, sometimes, untoward reactions. Occasionally a few such phenomena can be predicted on the basis of studies made on laboratory animals. The pharmaceutical manufacturer depends on physicians using new drugs to report all results observed, whether good, bad, or merely nuisance phenomena. Physicians too often hesitate to report any but successful experiences with a new compound; however, unfavorable but factual reports are not considered complaints. Prompt, accurate information on untoward or unnecessary results is equally as important as tabulations of benefits derived from a new drug. Physicians owe a duty to each other as well as to the manufacturer to look for and report all the clinical phenomena that follow use of any new type of treatment. Large pharmaceutical firms maintain staffs of physicians and assistants whose time is devoted largely to correspondence with other physicians on the innumerable questions that arise during therapy, whether with new or old drugs.

After the pharmaceutical manufacturer has assembled evidence on several features of a new drug, he may formally propose to the United States Food and Drug Administration that the drug be placed on sale. Prior to favorable action by the officers of this agency the new preparation may be distributed only to investigators whom the manufacturer lists as competent to study the effects of the drug in patients. Evidence that must be submitted to the Food and Drug Administration includes data on chemical composition, procedures used in manufacture, methods for assay as to potency and purity, data from studies in laboratory animals showing activity and toxicity of the drug, data from clinical trials demonstrating safety of the proposed dosage, evidence that the drug has least probable therapeutic value, and a statement of the claims to be made in labeling and in promotional literature.

Sound, prompt judgment on all these matters requires a large professional staff of high quality. Many men in the pharmaceutical industry feel an urgent need for greater funds to enable the Food and Drug Administration to train professional personnel. The activity of this agency is our most uniform guarantee of standards of purity, accuracy, and safety. This governmental agency is not charged with verifying all data and claims made. The Administration may inspect laboratories and plants, interview investigators, and make such laboratory examinations of the drug as judgment directs and facilities permit. It was clearly not the intention of Congress, which created this organization in 1938, that the medical officers of the Food and Drug Administration make clinical studies to determine either the safety or efficacy of new drugs. It should be noted that the Administration never endorses a new drug; it merely permits the manufacturer to proceed with sale of the drug under legally standardized methods of labeling. Approval must be gained directly from the physicians to whom the manufacturer presents his product.

Manufacturers rely on four chief approaches to the attention of the prescribing physician: journal articles, journal advertising, direct mail advertising, and the calls by "detail men." It is apparent that a large expenditure of thought and money is involved. Factors that have compelled producers to use such extensive promotional efforts are the number of new drugs, rapid evolution of medical practice to include objective methods of diagnosis, increase in specialization, and the competition inherent in our free enterprise system. With such a complicated situation no single method can be expected to carry the news of a new drug to all physicians. The manufacturer depends on the physician's professional desire to keep well informed. Each physician must choose the channels of communication within the profession to which he can give a bit of his precious time and attention. Unless this contact between the producer and prescriber is made, a new drug remains merely a new chemical on the shelf.

The members of the medical profession have provided a most important agency for discrimination and education in the matter of new drugs. The American Medical Association maintains a standing Council on Pharmacy and Chemistry. The members are pioneers in the effort to have approval accorded to drugs only when the evidence is adequate to convince men who are scientifically critical. This body serves without compensation at considerable expenditure of time and thought. Their contribution is another example of the noblesse oblige of which our profession is proud. Although at times manufacturers may experience delays or adverse decisions of the Council on Pharmacy and Chemistry, no one desires to discontinue this function of the American Medical Association. On the contrary, we cherish the right of a nongovernmental and extralegal group of physicians to make public their judgments about the products of pharmaceutical industry. The Council has been an important factor in the progress of American drug production.

EDUCATIONAL AND RESEARCH NEEDS

Another problem that is a mutual concern of the physician and the producer of drugs is the status of the educational process that provides physicians for our country's needs. How shall we provide clinical investigators we all demand? How can we augment our supply of trained pharmacologists? We also need chemists, engineers, accountants, executives, lawyers, writers, and all sorts of specially trained men.

Furthermore, let us admit frankly that were we to depend solely on the productivity of men in applied sciences and technology for the invention of new drugs, our progress would soon falter. The intimate although unpredictable dependence of these workers in the chemical and biological laboratories of industry on the fundamental contributions in physics, chemistry, biology and mathematics must not be overlooked. From even the point of view of the practicing physician or the producer of drugs we must regard all search for truth as worthy of our support. For all its man-made compartments, knowledge of truth admits no sharp boundaries between the disciplines that comprise a real university. This need for educational and research facilities in our universities is not peculiar to pharmaceutical industry or to medical science. It is fundamental to our evolving culture.

We must expect that the cost of such education and research will be borne not by a small segment of our people or our industries but by all of us. In this connection it may be noted, for example, that food manufacturers have reported sales 50 times as great as those of drug manufacturers in the United States. Food science and technology and many other industries also require research and technically trained personnel. Instead of special levies on specific industrial groups, educational funds are increasingly being provided by taxes, to which all industry contributes so largely.

On every hand one hears the suggestion that the pharmaceutical industry make larger contributions to medical education. I do not know whether the contributions now being made are adequate or fair; however, certain facts may be significant. Reports from the larger firms indicate that they are spending 5 to 6% of current income on research. The data further indicate that expenditures for research by producers of industrial chemicals are much smaller. Research funds in the pharmaceutical industry far exceed dividends to stockholders. This 5 or 6% for research is not considered a gift; it is an investment to provide future production. Although the major share of this money must provide for research in the manufacturers' laboratories, a portion is being used to meet the cost of research in universities and hospitals. Usually these grants provide for special expenses incurred by clinical investigators who accept the responsibility for studying a new drug. It may be noted that at present most such studies are not made conditional on grants by industry. When extraordinary expenditures are involved, of course, the manufacturer expects to meet the costs.

But the universities and larger hospitals are asking also for undesignated grants, funds to be applied to research at the discretion of the staff and not of the donor. We who direct clinical research and maintain extensive contacts with the medical schools and hospitals are keenly aware of the urgent need for such funds. But how far can the pharmaceutical industry go in meeting the need? A recent proposal envisages establishment in each medical school of a chair in clinical pharmacology. To provide the stipends for a trained investigator and for a staff to render his efforts effective an annual budget of $15,000 is requested. The plan and the objectives are not only reasonable but are urgently needed. We now have 72 medical schools in the United States. Can we expect to provide $15,000 chairs of clinical pharmacology in each of the 72? If not, who shall decide which schools shall have them?

Suggestions have been made that this type of support be provided by the trade organizations of pharmaceutical industries. Again certain facts are of importance. The U. S. Food and Drug Administration reports over 1,300 manufacturers of drugs that enter interstate commerce. But of these not more than 30 appear to be units with income large enough to make possible significant contributions to a program supporting research. These manufacturers are engaged in a competitive enterprise; thus if we are to have 72 chairs at $15,000 each, who shall determine the "voluntary" contribution of each firm? And if by some miracle of wisdom and good fortune this financial puzzle should be solved at once, which chair in the medical schools would be the next candidate for such annual support?

One method for meeting the need in clinical research and testing of new remedies has been suggested by those who are enthusiastic supporters of governmental activity. In recent years a magnificent and tremendous expansion of the facilities of the National Institutes of Health at Bethesda, Md., has been undertaken. This year the elaborate hospital, equipped both for patient care and for a great variety of laboratory studies, will be opened. An impressive group of the country's able investigators is being assembled to pursue studies extending from embryology to gerontology and pathology. Why not add clinical studies of proposed new drugs to the tasks assigned to the appropriate staff members? Obviously any manufacturer would gladly accept the opportunity to have his new drugs studied here. But the magnitude of the problem of examining new drugs precludes any possible adequate handling by even the imposing and growing National Institutes of Health. Furthermore, many feel that it is out of order to assign such functions to the government exclusively or even predominantly. These functions have traditionally been a part of free and competitive enterprise on the part of the manufacturers and of individual and independent judgment on the part of physicians. Assignment of clinical research to a government agency would remove the testing process far from the grass-roots of medicine.

These problems are neither simple nor insoluble. They are of great importance to physicians and pharmaceutical manufacturers alike. As we recognize the mutual interests of these two groups it is hoped that we may explore more actively the paths for extended travel. Our goals are fundamentally the same: the best treatment for patients.

Roche Park.

Emergency Tracheotomy.—An emergency tracheotomy is indicated for severe respiratory obstruction when facilities for intubation for the relief of the obstruction are not immediately available. . . . In order for the emergency tracheotomy to be successful an airway must be established beyond the respiratory obstruction which is producing suffocation, and the opening must be kept patent until respirations are re-established. . . . The physician should recognize at a glance the symptoms of marked obstructive dyspnea, that is, the ashen gray color or cyanosis, the labored, stridulous breathing and the retraction of the suprasternal notch and the supraclavicular fossa. The physician must realize that the obstruction will be fatal in a few minutes and therefore he must act immediately. . . . The patient is placed on his back with a pillow or pad under the shoulders and the neck extended. The thyroid notch and the ring of the cricoid are easily located by palpation. The thumb, second and third fingers of the left hand are arched over the larynx, and the soft tissues of the neck below the larynx are pressed backward on each side of the trachea, tightening the skin over the trachea below the cricoid ring. A bold, deep incision is made longitudinally in the midline from the cricoid ring downward, quickly cutting through all the tissues, exposing the tracheal rings. Should there be any difficulty in locating the midline of the trachea in the pool of blood, it can be palpated by the index finger. The incision is carried through the tracheal ring, preferably below the first ring. The tracheal incision is held open by forceps, knife handle or retractor of any type available to produce a free airway. The patient is turned on his side so that the blood will not run into the tracheal opening, and a tracheal cannula is procured. Artificial respiration is given and oxygen administered, if available, until the normal respiratory cycle is resumed.—W. B. Hoover, M.D., Emergency Tracheotomy, *Surgical Clinics of North America,* June, 1953.

CLINICAL NOTES

RUPTURE OF ABDOMINAL WALL THROUGH STRIA DISTENSA DURING CORTISONE THERAPY

S. H. Lawrence, M.D.
David Salkin, M.D.
Joseph A. Schwartz, M.D.
and
Harry C. Fortner, M.D., San Fernando, Calif.

Striae, or lineae cutis distensae, are band-like lesions associated with stretching of the skin. Although they occur oftenest during pregnancy, they are also found in other conditions, such as ascites. This is a report on a tuberculous patient treated with pneumoperitoneum who later had nephrosis, massive ascites, and striae. While he was being treated with corticotropin and cortisone, the striae became enormous, and one of them ruptured spontaneously, forming a peritoneocutaneous fistula. This case is reported because a survey of the literature fails to reveal records of any similar ruptures of the abdominal wall and because of the possible role of corticotropin and cortisone.

REPORT OF A CASE

A 27-year-old white man became ill in January, 1949, with productive cough and malaise. After a series of hemoptysic episodes in June, 1949, he was examined and found to have Mycobacterium tuberculosis in his sputum, and bilateral apical infiltrations seen on a roentgenogram. In July, 1949, the patient was admitted to a county hospital where pneumoperitoneum was initiated, and he was given streptomycin, 2 gm. weekly intramuscularly. In January, 1950, he was transferred to a Veterans Administration hospital, where he remained until Oct. 19, 1951. During this period pneumoperitoneum was continued, and he received courses of streptomycin, *p*-aminosalicylic acid, and amithiozone (Tibione). He received a total of 92 pneumoperitoneum refills. In January, 1951, albuminuria was noted. Peritoneal fluid was first noted fluoroscopically on Oct. 12, 1951, although it may have been present in smaller amounts for some months. Three days later a paracentesis was done, and 1,500 cc. of yellow, opalescent fluid was aspirated. The patient was transferred to the San Fernando Veterans Administration Hospital on Oct. 19, 1951.

On admission he appeared acutely ill and much older than his age because of numerous facial wrinkles. His skin generally was atrophic and showed patches of brownish pigment, especially around the lips. The abdomen was markedly distended with ascites, and reddish striae were present; many well-healed needle scars were seen on the left side where pneumoperitoneum had been done. The blood pressure was 100/80 mm. Hg.

Laboratory Findings.—The urine had a specific gravity of 1.025, 2+ albumin, and contained both red and white blood cells. The red blood cell count was 4,500,000 per cubic millimeter, hemoglobin level 12.3 gm. per 100 cc., and hematocrit 35%. The white blood cell count was 15,000 per cubic millimeter, with 70% neutrophils, 27% lymphocytes, 2% eosinophils, and 1% monocytes. Blood urea nitrogen was 4 mg. per 100 cc., total protein 2.9 gm. per 100 cc., albumin 0.9 gm. per 100 cc., and globulin 2 gm. per 100 cc. The sputum contained Myco. tuberculosis, and the chest roentgenogram showed extensive bilateral apical infiltrations, with multilocular cavitation on the left side. A Thorn test with corticotropin was normal.

Course.—Shortly after the patient was admitted, edema of the feet and scrotum developed. He was given a low-sodium diet and hydrogen-ion exchange resins, but there was no improvement. The abdomen showed progressive enlargement and tension. The striae became wide and measured up to 40 mm. in width. A paracentesis done on Dec. 13, 1951, in the lower left quadrant yielded 7,000 cc. of a greenish, opalescent fluid. Because he showed the nephrotic syndrome, 40 mg. of corticotropin was given daily. After 26 days no beneficial effect was noted. On Jan. 8, 1952, corticotropin therapy was discontinued, and 12.5 mg. of cortisone was given daily. On Dec. 31, 1951, another aspiration had yielded 7,500 cc. of fluid.

At this time the brown pigmentation of the abdominal skin increased, and the striae became more numerous and wider, some measuring 60 mm. in width. The edges had a purple cast, and the central portions resembled fine, white tissue paper. A necrotic area developed over the coccyx, and several other pressure areas became reddened and thickened. On Jan. 21, 1952, a small, 4 mm., irregular longitudinal tear occurred in the center of a wide stria in the lower right quadrant of the abdomen. Ascitic fluid drained through the ostium, and it was necessary to keep the draining area heavily padded. The patient died on Jan. 28, 1952.

Autopsy Findings.—The body was that of an adult, emaciated, white man with an increase of brownish pigment over the entire body and edema of the feet and ankles. The skin over the abdomen had numerous wide striae measuring 60 mm. in width on the right side of the abdomen. There was a denuded area 20 mm. in diameter covered with gray exudate and containing a central 4 mm. sinus opening that led into the peritoneal cavity. The anterior abdominal wall was edematous, and the muscles were very thin. The abdominal cavity contained 6 liters of yellow fluid, and visceral and parietal layers of peritoneum had whitish, dull, thickened patches.

Large apical cavities and numerous, scattered caseous foci were found in both lung fields. The heart weighed 245 gm. and was essentially normal; the coronary vessels were elastic and had no plaques. There were only a few small plaques in the aorta. The liver weighed 1,100 gm. and was otherwise normal. The spleen weighed 230 gm., was firm, and gave a positive iodine-sulfuric acid test for amyloid. The gallbladder and pancreas were normal. The right and left adrenal glands were enlarged and weighed 11 gm. and 10.4 gm. respectively; the zones were distinct. There were numerous small ulcerations in the terminal ileum, the cecum, and the ascending colon. The right kidney weighed 220 gm. and was located normally. The left kidney weighed the same but was located below the bifurcation of the abdominal aorta at the level of the fourth lumbar vertebra. The kidney was rotated so that the ureter faced anteriorly. On section, both kidneys had a widened cortex with punctate yellow foci and gave a positive amyloid test. No abnormalities were found in the urinary bladder, testes, prostate, thyroid, brain, or pituitary gland.

Microscopic examination revealed many caseous areas with cavitation in the lungs but only a few giant cells; the pulmonary artery had slight medial calcification. Caseation was present in the mediastinal lymph nodes. The intestinal ulcers contained caseation without giant cells. The liver contained numerous minute tubercles and a small amount of amyloid subintimally in the vessels. There were heavy amyloid and brown pigmented deposits in the spleen. The kidneys had intercapillary amyloid deposits in nearly all the glomerules; vacuolar changes had occurred in the proximal tubules, which stained poorly. The distal tubules were dilated, and amyloid deposits were present between them. The adrenal glands contained diffuse amyloid throughout, especially in the cortex, but least in the zona glomerulosa. The brain was slightly edematous. The pituitary and thyroid glands were normal. There was intracellular and extracellular brown pigment in the bone marrow.

From the San Fernando Veterans Administration Hospital and the departments of medicine and infectious diseases, School of Medicine, University of California at Los Angeles.

The chief pathological diagnoses were: (1) pulmonary tuberculosis with caseation and cavitation; (2) tuberculous ulcerative enterocolitis; (3) amyloid disease of the kidneys, adrenals, and spleen; (4) nephrosis due to amyloidosis; (5) anomalous location of left kidney; (6) ascites; and (7) abdominal striae distensae with sinus tract formation in the lower right quadrant.

COMMENT

A review of the literature reveals that stria formation is more complex than is ordinarily supposed, and much remains to be discovered of its etiology and pathogenesis. Striae have been described in a large variety of conditions: (1) pregnancy; (2) distention caused by ascites, large abdominal tumors, rapid gain of weight, rapid increase in growth; (3) infections such as typhoid, typhus, leprosy, syphilis, and meningitis, especially in children and adolescents; (4) endocrine disorders in puberty, Cushing's syndrome, and pituitary and adrenal tumors; and (5) miscellaneous conditions, such as spondylitis deformans and certain nervous system diseases.

Striae occur perpendicularly to the lines of maximal tension. On the abdomen they cut across Langer's lines; on a limb they are transverse during longitudinal growth, and are longitudinal if the growth is chiefly circumferential. Pathologically, striae show rupture and retraction of the fibroelastic bundles of the corium, thus revealing the underlying vascular plexuses and producing a purplish color; in the later stages, the vessels are atrophied, and the striae appear white and silvery.

The pathogenesis of stria formation is not clear.[1] Since distention is present in practically all cases, it is believed that stretching of the skin is the primary cause, but apparently constitutional, hormonal, toxic, nutritional, and neurotrophic factors are also important. The degree of stria development in pregnancy varies with respect to race and individual body structure.[2] They also occur in conditions with little skin tension and are relatively rare in ascites and large abdominal tumors. Striae are also seen in nonpregnant women.[3] They commonly occur in adolescence, are consistently present in Cushing's syndrome, and develop in many infections. These secondary factors apparently further weaken the elastic and collagenous fibers of the skin and make them more vulnerable to damage by the pressure of distention.

Corticotropin and cortisone probably play an important role in stria formation occurring in Cushing's syndrome, and they (or similar hormones) are also important in stria formation due to pregnancy, constitutional structure, and perhaps infections. Alrich, Carter, and Lehman [4] have shown that cortisone retards wound healing by decreasing the production of collagen and delaying the proliferation of fibroblasts, which results in a wound closure of low tensile strength. The fact that we were unable to find a similar case of abdominal rupture through a stria and that this patient received both corticotropin and cortisone suggests that the hormones further damage an already weakened abdominal wall, with resultant rupture through the weakened area. Corticotropin and cortisone should probably be used with caution in cases of abdominal distention with stria formation.

SUMMARY

This is the first report of a rupture of the abdominal wall through a stria cutis distensa. The factors influencing stria formation are discussed with special reference to corticotropin and cortisone.

MUMPS SKIN TEST DURING A MUMPS EPIDEMIC

Victor J. Cabasso, D.Sc., Pearl River, N. Y.
and
Col. Robert J. Hoagland (MC), U. S. Army

In their work "Immunity in Mumps" Enders and his associates [1] reported that persons having previously contacted mumps virus in the subclinical or clinical forms exhibited dermal hypersensitivity on intradermal inoculation of small amounts of heat-inactivated virus. These authors have found that, on the whole, this phenomenon correlated satisfactorily with a state of resistance against infection by mumps virus. They also proposed the following criteria for the interpretation of the skin reaction: an erythema of 10 mm. mean diameter or less should be considered to be a negative response; an erythema between 11 and 15 mm. in diameter should be considered a doubtful response; and an erythema over 15 mm. mean diameter should be regarded a positive reaction indicative of the resistant state. They used skin test antigens prepared from infected monkey parotid gland or from infected amniotic sacs with equally good results. Habel [2] confirmed the observations of Enders and co-workers and obtained slightly better results with chick embryo than with monkey parotid gland skin test antigens. Florman [3] used an egg-grown virus killed by formaldehyde (Formalin) and partially purified by centrifugation in study of the epidemiology of mumps in household groups such as seen in private pediatric practice in New York City. They also obtained evidence that a positive skin

test was related to a resistant state and that a positive reaction developed several months after onset of the disease. They arrived at the conclusion that the test is useful in practice to determine susceptibility to mumps. Muntz and others [4] prepared a skin test antigen from killed egg-propagated virus and demonstrated that a hypersensitive reaction appeared in persons who had had previous contact with mumps virus.

We present here the results obtained by skin testing of persons involved in a small mumps epidemic at West Point, N. Y. Although the number of patients tested is limited, it does present enough variety to show the different situations that may be encountered by a clinician during a mumps epidemic.

TABLE 1.—*Clinical Cases of Mumps During Epidemic*

Case	Sex	Age, Yr.	Mumps History	Mumps During Epidemic; Date of Onset	Date of Skin Test	Skin Test Readings, Mm.		Remarks
						Mumps	Control	
1	M	28	None	2/26/49	2/27/49 6/ 2/49	10.0 20.0	0 1.0	Showed a marked increase of skin hypersensitivity three to four months after mumps onset.
2	F	2½	None	2/19/49	2/11/49	0	0	Brother and sister; at time of skin test, another brother had active mumps; skin test disclosed that both of these were susceptible to infection; both came down with mumps a few days later. These patients were unavailable for retesting.
3	M	4	None	2/20/49	2/11/49	0	0	
5	M	6	None	2/ 9/49	2/21/49 10/ 1/49	11.5 15.0	0 0	First tested 12 days after onset of mumps; gave a reaction considered as doubtful according to Enders' classification. Skin reaction was positive eight months after onset.
6	M	2½	None	2/26/49	2/28/49 7/ 2/49 10/ 3/49	1.5 12.0 10.0	1.5 0 1.0	Reaction to skin test was negative at time of onset; definite increase of skin sensitivity four and seven months after onset.
11	M	9½	None	4/26/49	6/30/49	13.5	10.0	Two brothers and a sister were not tested prior to onset of mumps. On 4/26/49, patient in case 11 had slight induration behind right mandible and pain when he chewed. Induration persisted, with no increase, for five days. Sixteen days later, sister (case 12) had fullblown mumps, and two days later brother (case 13) had mumps. Doubtful skin reactions were obtained on patients in cases 11 and 12 two and a half months after onset. Patient in case 13 gave weak reaction. Patients were unavailable for retesting.
12	F	3½	None	5/12/49	6/30/49	11.0	1.0	
13	M	7	None	5/14/49	6/30/49	8.2	0	
16	M	20	None	7/16/49	7/16/49 7/31/49 9/21/49	2.0 2.0 10.0	0 0 0	Skin test negative at time of onset; patient showed increased skin hypersensitivity two months later, but reading still low.
17	M	19	None	7/ 9/49	7/ 9/49 7/21/49 8/18/49	0 2.0 4.0	0 4.0 4.0	Skin test negative at time of onset. No skin sensitivity had developed two months later.
18	M	21	None	6/28/49	6/28/49 7/ 5/49 7/18/49 9/19/49	0 0 10.0 11.0	0 0 0 0	Patient in case 20 did not have parotitis but had bilateral orchitis and epididymitis with low blood cell count and normal differential. Roommate (case 19) was admitted to hospital on same day, with typical mumps parotitis. Both had been exposed about two and a half weeks previously to patient in case 18. All three presented increased skin sensitivity after onset of illness.
19	M	21	None	7/15/49	7/17/49 7/30/49 9/20/49	0 0 8.0	0 0 0	
20	M	23	None	Admitted to hospital on 7/15/49 with bilateral orchitis and epididymitis	7/17/49 7/30/49 9/17/49	0 2.0 16.0	0 0 0	

MATERIALS AND METHODS

Mumps Virus.—The strain of mumps virus used for the preparation of the skin test antigen was supplied to us by Dr. Karl Habel of the National Institutes of Health. It was propagated in our laboratory in 8-day-old embryos, and infected allantoic fluid was harvested after seven days incubation at 35 C. Normal allantoic fluid was obtained from 8-day-old eggs inoculated with sterile broth and treated in the same manner as infected eggs.

Preparation of Mumps and Control Antigens.—These antigens were prepared from infected and normal allantoic fluids, respectively. We used essentially the same procedure as that described by Enders [5]; one part of allantoic fluid was added to two parts of saline. The pH of the mixture was between 6.8 and 6.9. It was heated for 20 minutes at 65 C and centrifuged at 3,500 rpm for 30 minutes. The final concentration of the allantoic fluid was brought to 1:10 by the addition of saline containing enough phenol to give a final concentration of 0.5% of the preservative. The two antigens were then distributed in vials containing 5 cc. amounts and were tested for purity and safety.

Skin Testing.—Each person tested received intradermally, on the anterior surface of the forearm, 0.1 cc. each of the mumps and control antigens. Injections were made on the same forearm 5 to 6 cm. apart in order to avoid overlapping of reactions. Reading of largest and smallest diameters of erythema were made 24 and 48 hours after injection, and the average diameter was calculated on that basis.

RESULTS

Twenty-three persons were involved in this mumps epidemic, which extended over a period of five months. Ages ranged from 2½ to 38 years. There were 16 males and 7 females. Clinical mumps developed in 13 persons during the course of the epidemic; the other 10 were either persons who contacted others with mumps or persons who presented indurations or swellings in the postmandibular or preauricular regions that were later found to be caused by conditions other than mumps. For the sake of convenience the descriptions of all cases, as well as the results of the skin tests, have been tabulated under these different headings: (1) clinical cases of mumps during epidemic (table 1); (2) patients presenting indurations and swellings not caused by mumps

(table 2); and (3) persons with negative or positive skin test who contacted others with mumps in whom mumps did not develop (table 3).

COMMENT

There are three situations in which the clinician can secure aid from skin testing in clinical cases of apparent mumps or in persons exposed to patients with mumps. First, and probably of greatest value, is the positive skin test in a person whose clinical manifestations closely resemble mumps. As is well known to anyone with experience in general practice, pediatrics, or internal medicine, the early manifestations of mumps and the infrequent cases of mumps with mild parotid involvement do not permit easy diagnosis; therefore, when a patient with an induration behind the ramus of the mandible suggestive of mumps is skin tested, he can be released from isolation within 24 or 48 hours if the skin test is strongly positive and, thus, indicates immunity to mumps. Examples of such instances are cases 7, 21, and 23 in table 2. Although the patients in cases 7 and 23 had histories of mumps, the positive skin tests were of great help in excluding the possibility of a second infection. In case 21, on the other hand, there was no history of mumps, and, so, the positive skin test was of especially great diagnostic weight. A further diagnostic problem is presented by patients who have an obvious acute parotitis that may be caused by conditions other than mumps. Before the availability of skin testing, one of us (R. J. H.) encountered several such patients. The differential diagnosis, once calculus of Stenson's duct was excluded, was dependent on history, duration of the parotitis, and the blood cell count. If there was no leukocytosis and if a history of mumps was absent or unreliable, it would probably have been clinically impossible to make, or to disprove, a diagnosis of mumps without a skin test.

TABLE 2.—*Patients with Indurations and Swellings Not Caused by Mumps*

Case	Sex	Age, Yr.	Mumps History	Date of Skin Test	Skin Test Reading, Mm. Mumps	Skin Test Reading, Mm. Control	Remarks
7	M	21	Mumps in 1940	3/ 7/49	18.0	2.0	Induration behind the ramus of mandible did not progress like mumps. Follow-up definitely confirmed that it was not mumps. Skin test was useful in excluding mumps.
10	M	21	None	4/ 2/49	9.5	2.0	Enlarged submental lymph node developed; skin test suggested that patient might be susceptible to mumps, but the course of illness showed that it was not mumps. This patient was unavailable for retesting.
21	F	38	None	7/19/49	20.0	1.0	Skin test disclosed that patient was resistant to mumps. She had, however, a swelling behind the left mandible that lasted only two days. Clinically not mumps, leukocytosis.
22	M	21	Mumps in 1937	10/31/49	21.0	1	Gave an immune reaction, but showed an indefinite induration behind ramus of right mandible not clinically suggestive of mumps.
23	M	22	Mumps in 1942	11/17/49	12.0	0	Appeared with acute, painful, tender swelling of right submaxillary gland; opening of Stenson's duct red and swollen; blood cell count normal. Size of swelling fluctuated slightly between meals, and gritty material was expelled from duct. Diagnosis: calculus of Stenson's duct.

TABLE 3.—*Persons Exposed to Mumps in Whom Mumps Did Not Develop*

Skin Test Reaction	Case	Sex	Age, Yr.	Mumps History	Date of Skin Test	Skin Test Reading, Mm. Mumps	Skin Test Reading, Mm. Control	Remarks
Negative	8	F	7	None	3/ 8/49	5.0	0	Mother and daughter lived in small trailer with another woman whose child had mumps. They were in the same trailer during first day of disease; neither contracted mumps. One might have assumed that they were immune to mumps inasmuch as they did not become sick. Skin test at time of onset, however, disclosed that both were susceptible, and later test seemed to indicate that they were merely fortunate in not making adequate contact with the virus. This exposure and failure to develop the disease, or immunity, is an interesting side-light on the contagiousness of mumps.
					6/18/49	3.0	0	
	9	F	30	None	3/ 8/49	4.5	9.0	
					6/18/49	4.0	4.0	
Positive	4	F	36	Mumps during childhood	2/11/49	20.0	0	Skin test disclosed that this woman was resistant to mumps. She was the mother of patients in cases 2 and 3; mumps did not develop despite repeated contact with the patients.
	14	M	37	Unknown	7/21/49	17.2	2	Parents of patients in cases 11, 12, and 13. To their knowledge, they had not had mumps. Skin test, however, disclosed them to be immune, and exposure to affected children did not result in clinical disease.
	15	F	37	Unknown	7/21/49	21.0	1	

A second advantage to the clinician is the possibility of making a diagnosis of nonparotid mumps. This is illustrated by the patient in case 20; there was a change from a negative to a positive skin test over a period of time in a patient who never had parotitis but who did have mumps involvement of another organ. This is of more than academic interest because social problems involving venereal disease are eliminated; and, furthermore, the patient can consider himself immune to mumps on subsequent occasions when knowledge of such immunity will allow latitude of activity.

A third advantage is that the clinician is aided because he can perform skin tests on exposed children who are not sick, and, if the results are strongly positive, he can freely tell the parents that they need not fear the occurrence of mumps. Any practicing physician knows that such assurance may make a great difference in plans for trips, vacations, and other activities. In military service, for example, a positive skin test might make the difference in whether or not a person would be allowed to board an Army transport.

SUMMARY

A positive skin test with mumps antigen, like a positive tuberculin skin test, indicates past invasion of the body by the causative agent; however, unlike the tuberculin test, a positive mumps skin test indicates a state of resistance to mumps and, consequently, immunity to infection.

Skin testing is a simple method of determining susceptibility or resistance to mumps and allows the clinician to infer (1) that an acute disease physically resembling mumps parotitis is actually mumps if a negative skin test is obtained but is not if the result is positive; (2) that an acute disease without associated parotitis, such as acute epididymo-orchitis or acute meningitis, was caused by mumps virus if the skin test was initially negative but became positive two or three months later; (3) that persons recently exposed to mumps but shown to have positive skin tests will not contract the infection; and (4) that persons recently exposed but who show negative skin tests should be considered susceptible to mumps, and no prediction can be made as to whether they will have mumps.

INFECTIOUS MONONUCLEOSIS ASSOCIATED WITH SYMPTOMS OF ACUTE PERICARDITIS

Louis A. Soloff, M.D.
and
Jacob Zatuchni, M.D., Philadelphia

Both infectious mononucleosis and acute benign, or so-called nonspecific, idiopathic, or primary, pericarditis are disorders of unknown cause that tend to occur commonly in young persons and are often preceded by symptoms suggestive of a mild infection of the upper respiratory tract.[1] The pathological changes in infectious mononucleosis are widespread, and the clinical picture is highly variable, depending on the intensity of the localization of the pathological changes that produce symptoms and signs. The pathological changes in acute benign pericarditis are confined to the pericardium and possibly to the adjacent tissues, so that the clinical picture is fairly constant, except for variability in intensity of symptoms and signs. The diagnosis of infectious mononucleosis can, however, be firmly established by specific laboratory studies, whereas acute benign pericarditis remains a clinical concept and is an admission by the clinician of his inability to uncover a specific cause. Perhaps the increase in viral diagnostic laboratory facilities will help in the classification of this clinical entity according to specific causes. Meanwhile, it is important that every effort be made to exclude systemic or adjacent organ disease, among other known causes of pericarditis,[2] before a diagnosis of acute benign pericarditis is made. Our purpose is to report a rare instance of a patient who had the clinical picture of acute benign pericarditis that was proved to be due to infectious mononucleosis.

REPORT OF A CASE

The patient was referred by Dr. Philip Clair to one of us (L. A. S.) and was first seen on Nov. 12, 1952. He had severe, agonizing pain located primarily substernally and radiating across the anterior chest wall upward toward both shoulders and downward to the epigastric region. His family physician had made a diagnosis of acute benign pericarditis but wanted to exclude the possibility of myocardial infarction because of the severity of the pain and its duration and recurrence.

The patient was a white boy, 17 years old, who had regarded himself to be in good health, until Nov. 11, 1952, when he awoke feeling unwell. He had no specific complaints, however, and went to his place of work, where he is a cashier outside school hours. Later in the same day, he felt feverish and had vague pains across the anterior chest wall, which radiated toward both shoulders. He applied an ointment to these regions for relief. That evening, the pain became agonizing and the family physician was called. The physician found it necessary to give him morphine sulfate for relief of pain, after which he fell asleep. He was awakened at 2 a.m. by similar pain across the anterior chest wall, which radiated to the epigastrium and was accompanied by nausea. Again, an injection of morphine sulfate had to be given for relief of pain, and the patient fell asleep. On the following morning, he awoke with a recurrence of pain, nausea, and a sensation of chilliness.

Physical examination on Nov. 12 revealed a normally developed, normally nourished young man who complained of pain in the chest. He felt slightly short of breath. Deep breathing and change of position increased the intensity of the pain. Except for slight tachycardia, the heart seemed normal on physical examination. An electrocardiogram confirmed Dr. Clair's diagnosis of acute pericarditis. General physical examination revealed, however, small lymph nodes in the cervical, axillary, and inguinal regions. Although the presence of these lymph nodes in the cervical and inguinal regions did not necessarily signify active disease, it was thought that the axillary lymph nodes were larger than would be expected normally. For this reason, the possibility of a lymphomatous disorder, with secondary pericardial involvement, was considered.

The patient was admitted to Temple University Hospital Nov. 15, 1952, for study. In the hospital, the results of physical examination were unchanged, except for the occasional occurrence of premature beats and accentuation of the pulmonic second sound. Fluoroscopic and roentgenographic study of the chest revealed a normal cardiac silhouette, normal lung fields, and normal excursion of the diaphragm. An electrocardiogram made Nov. 17 showed the pattern of subsiding pericarditis. The venous pressure was 150 mm. H_2O, the dehydrocholic acid (Decholin) time was 14 seconds, and the ether time was 6 seconds. The hemoglobin level was 15 gm. per 100 cc., the hematocrit 46%, the leukocyte count 13,700 per cubic millimeter, and the erythrocyte sedimentation rate 11 mm. in 1 hour (Wintrobe, corrected). A blood smear showed 29% neutrophils, 53% lymphocytes, 5% atypical lymphocytes, 1% prolymphocytes, 8% monocytes, and 4% disintegrated cells. Serologic tests for syphilis gave negative results. The heterophil antibody titer was 1:1792 on Nov. 19 and 1:896 on Nov. 21. Results of urinalysis were normal. On Nov. 20, examination of the blood revealed 12,300 leukocytes per cubic millimeter, with 22% neutrophils, 55% lymphocytes, 11% atypical lymphocytes, 1% prolymphocytes, 4% monocytes, 1% basophils, and 6% disintegrated cells. An electrocardiogram made Nov. 20 showed an upper nodal rhythm. The P vector was directed −90 degrees anteriorly. The P-R interval was 0.1 second.

For the first three days of hospitalization, the patient's temperature was elevated variably to as high as 101.8 F, but by the fourth day it had returned to normal. The patient received oxytetracycline, 500 mg. every 6 hours. The symptoms disappeared shortly after hospitalization, and the patient was discharged Nov. 21, 1952.

On Nov. 26, results of blood studies were as follows: hemoglobin level, 15 gm. per 100 cc.; erythrocyte count, 5,400,000 per cubic millimeter; leukocyte count, 9,000 per cubic millimeter, with 32% neutrophils, 59% lymphocytes (many abnormal), 7% monocytes, and 2% basophils, and heterophil

antibody titer, 1:224. Repeated electrocardiograms showed normal sinus rhythm and sequential changes in the ST-T portion of the electrocardiogram consistent with a subsiding pericarditis. The last electrocardiogram, made April 6, 1953, showed a normal sinus rhythm and a decreased voltage of the T waves. At present, results of laboratory studies are negative, and the patient is well and is attending school and working after school.

COMMENT

If the lymphadenopathy had not been discovered, this young man would have been regarded as having had acute nonspecific or idiopathic pericarditis. It is possible for the diagnosis of infectious mononucleosis to be missed also because the leukocyte count in the early stages of the illness is not characteristic and because there is no significant rise in sheep cell agglutinin titers until long after the onset of the disease.[3]

Cardiac involvement in infectious mononucleosis is usually found accidentally during a routine electrocardiographic examination. The literature has been reviewed recently by Leibowitz.[4] Some workers have reported electrocardiographic abnormalities in as many as 41% of persons with infectious mononucleosis.[5] Most commonly, the abnormalities consist in minor changes in the amplitude of the T waves, as may be seen in any infection. The occurrence of premature beats, prolongation of the P-R interval, and even second degree heart block have been reported as well as alterations in the ST-T portion of the electrocardiogram.[6] In almost all instances, clinical symptoms due to cardiac involvement are absent. Occasionally, the occurrence of a systolic murmur, which is in no way different from the systolic murmur frequently found in febrile illnesses, has been reported.[7] A case has been reported of mitral stenosis following infectious mononucleosis, but the relation may be purely temporal rather than causal.[8] In the few reports of necropsies that are available, the presence of lymphocytic and monocytic cellular infiltration of the myocardium is mentioned.[9]

Pericardial involvement in infectious mononucleosis, recognized clinically or electrocardiographically, is rare. Only four instances have been reported, and two have been mentioned incidentally in the literature.[10] All the patients had either ST segment or T wave changes or both. Two had a friction rub, and two had pericardial effusion. Our patient had both clinical and electrocardiographic evidence of acute pericarditis and, also, transient upper nodal rhythm. Serial electrocardiographic tracings in our patient show the typical sequential changes of acute pericarditis. The last tracing, taken four and one-half months after the onset of illness, is still not entirely normal. Clinically, the patient is well.

SUMMARY AND CONCLUSIONS

1. A case of infectious mononucleosis is reported in which the first symptoms were those of acute pericarditis.

2. The diagnosis of acute, benign, nonspecific or idiopathic pericarditis should be made only when all known causes of acute pericarditis have been excluded by a carefully taken history, a thorough physical examination, and pertinent laboratory tests.

Broad St. at Ontario (40) (Dr. Soloff).

EXTREME HYPERGLYCEMIA AND SEVERE KETOSIS WITH SPONTANEOUS REMISSION OF DIABETES MELLITUS

Tsung O. Cheng, M.D.
Robert C. Jahraus, M.D.
and
Eugene F. Traut, M.D., Oak Park, Ill.

From time to time extreme hyperglycemia has been recorded. We wish to report on a patient who had an unusually high blood sugar but, after surviving profound and prolonged coma, apparently recovered completely from all symptoms and signs of diabetes mellitus.

REPORT OF A CASE

A 68-year-old Negro woman was admitted to the Cook County Hospital, Chicago, on July 3, 1952, in a coma. She had been well until three months previously, when she began to note unusual thirst and weakness. On the day before admission the patient had felt generally and indefinitely ill. She went to bed early that night, thinking that she might have a cold, and was found unconscious in bed the next morning. Her history previous to the three months before admission was irrelevant, and there was no known diabetes in her family.

On admission the patient appeared to have extreme ketosis. Kussmaul's breathing with an acetone odor was present. The skin was dry and florid, and the eyeballs were soft. The rectal temperature was 98.2 F. Other than generalized hyporeflexia, unconsciousness, absence of a pupillary reaction to light, and elicitation of Babinski signs, there were no abnormal neurological signs and, in particular, no focal signs of a neurological lesion. The blood pressure was 110/80 mm. Hg, and the pulse rate was 108 per minute. The leukocyte count was 14,300 per cubic millimeter. Chemical analysis of the blood revealed 1,170 mg. of sugar per 100 cc., carbon dioxide combining power 10 vol. %, nonprotein nitrogen 76 mg. per 100 cc., creatinine 5 mg. per 100 cc., sodium 141 mEq. per liter, chloride 98 mEq. per liter, and potassium 5.6 mEq. per liter. Urinalysis showed 4+ sugar and 4+ acetone. The spinal fluid was under slightly increased pressure but otherwise was normal.

The patient was given 100 units of regular insulin intravenously and 100 units subcutaneously, on admission; in addition, 850 cc. of isotonic sodium chloride solution and 150 cc. of one-sixth molar sodium lactate solution were administered simultaneously. Three hundred thousand units of procaine penicillin and 1 gm. per day of streptomycin were injected to prevent respiratory infection. Therapy during the first 24 hours is shown in the table.

Altogether, 1,425 units of regular insulin and 10,350 cc. of fluids were given within the first 24 hours of coma. The chemical and physical signs of ketosis disappeared in 24 hours, but the patient remained in a coma for five days. She received 2,000 cc. of 5% glucose in isotonic sodium chloride solution, 1,000 cc. of isotonic sodium chloride solution, 150 cc. of one-sixth molar sodium lactate solution and 4 gm. of potassium chloride daily parenterally.

The patient was fully conscious on the sixth hospital day and showed no neurological symptoms or signs. A liquid diet consisting of 300 cc. of milk every 6 hours alternately with 240 cc. of orange juice every 6 hours was given to the patient every 3 hours. On the eighth day she was given a diet yielding 120 gm. of carbohydrate, 60 gm. of protein, and 70 gm. of fat. After the first 24 hours on this regimen, the insulin dose was lowered progressively from 250 units per day to 175 units, 150 units, 100 units, 80 units, 50 units, 40 units, and 10 units per day, during a period of one week. A daily dose of 10 units of regular insulin was continued for one month, after which 5 units were given daily for a few more days. Finally no insulin was given at all. After the first 24 hours on the diet the patient had no glycosuria or hypoglycemia.

Fasting blood sugar determinations (milligrams per 100 cc.) during her hospital stay were as follows:

July 5	550
7	332
8	365
14	80
18	135

She was discharged on Aug. 21, 1952, with glycosuria and hyperglycemia controlled on a regimen of 150 gm. of carbohydrate, 80 gm. of protein, and 80 gm. of fat daily.

The patient was readmitted in November for further metabolic studies. During her second hospitalization she showed no glycosuria. Her fasting blood sugar level ranged between 100 and 110 mg. per 100 cc. of blood. An insulin tolerance test was performed with the use of 7 units of regular insulin (calculated on the basis of 0.1 unit per kilogram of body weight). The fasting blood sugar of 107 mg. per 100 cc. was reduced to 60 mg. per 100 cc. in 25 minutes by intravenous injection of 7 units of regular insulin, returning to 85 mg. per 100 cc. at the end of two hours. In a glucose tolerance test, the fasting blood sugar level of 100 mg. per 100 cc. rose to 124 mg. per 100 cc. one-half hour after the ingestion of 75 gm. of dextrose. One hour later it was 200 mg. per 100 cc. In two hours it was 158 mg. per 100 cc.; three hours after administration of the glucose it was 67 mg. per 100 cc. The patient was given a diet yielding 340 gm. of carbohydrate, 90 gm. of protein, and 100 gm. of fat for two days. There was an excretion of 0.75 gm. of glucose in the 1,230 cc. of urine representing a 24 hour excretion. A blood sample taken two hours after the breakfast while the patient was on the diet showed the blood sugar to be 110 mg. per 100 cc. Other endocrine tests revealed a normal Robinson, Power, and Kepler test for Addison's disease; excretion of 6.3 and 6.5 mg. of 17-ketosteroids per 24 hours on two successive days; basal metabolic rate −8%; and I^{131} uptake of 14%. From the standpoint of renal function, the urinalysis showed no abnormalities. The nonprotein nitrogen was 26 to 30 mg. per 100 cc. Phenolsulfonphthalein excretion was 65% within two hours after intravenous injection of the dye. The pyelogram was normal. Liver function tests yielded a negative cephalin cholesterol flocculation test and a thymol turbidity of 6 units per 100 cc. Serum cholesterol was 238 mg. per 100 cc., and total protein 7.8 gm. per 100 cc., with a normal albumin to globulin ratio. Serum amylase was 8 units per 100 cc. The gastrointestinal tract and skull were roentgenologically normal.

Therapy and Condition of Patient in First Twenty-Four Hours

† Glucose in isotonic sodium chloride solution.

COMMENT

An extraordinarily elevated blood sugar level is usually associated with severe diabetic symptoms. While serious, it cannot be taken as a necessarily bad omen. Joslin[1] reported 38 cases of diabetic coma that had blood sugar levels of 1,000 mg. per 100 cc. or higher, the highest being 1,620 mg. per 100 cc.; 29 recovered from coma, and 9 died. Dillon and Dyer[2] reported on 25 patients from the Philadelphia General Hospital with blood sugar levels on admission of 1,000 mg. per 100 cc. or more; 9 recovered, and 16 died. The highest blood sugar they reported was 1,850 mg. per 100 cc. in a 21-year-old girl; she recovered from the coma. Brodribb[3] reported a blood sugar level of 2,000 mg. per 100 cc. in a 67-year-old woman who recovered from coma. The blood sugar in the patient of Meyer and Salt[4] was 2,100 mg. per 100 cc. after administration of 660 units of insulin and 320 gm. of glucose. The patient recovered from the ketosis. High blood sugar values in cases terminating fatally have been reported by others; in Lawrence's case, the blood sugar value was 2,060 mg. per 100 cc.; in Argy's, 1,710 mg. per 100 cc.; in Pitfield's, 1,700 mg. per 100 cc.; and in Olmsted's, 1,400 mg. per 100 cc.

The duration of unconsciousness before treatment is begun significantly affects the prognosis. According to Joslin,[1] in a patient unconscious 8 hours (12 hours according to others) the outlook is grave. In our case the duration of unconsciousness before treatment was estimated to be at least 10 hours. The patient did not regain full consciousness for five days. We used the arbitrary standards of Dillon and Dyer[5] for determination of unconsciousness and those of Rabinowitch, Fowler, and Bensley[6] in defining coma. Such a long period of unconsciousness almost always precludes recovery, according to Rabinowitch, Fowler, and Bensley[6] and to Owens and Rockwern.[7] The age of the patient also has an important bearing on the prognosis. Joslin[1] indicated the increased danger of coma with advanced age, the highest mortality occurring in the sixth decade. Our patient was 68 years old.

The patient's insulin requirements fell until finally she required none. Results of a glucose tolerance test three months after the acidosis were normal. She did not excrete more than 1 gm. of sugar in her urine in 24 hours, even on a high carbohydrate diet; she was clinically "cured" of her diabetes. She has been free of dietary restrictions for five months, enjoys pastries, ice cream, and other carbohydrate-rich foods with no resulting glycosuria or hyperglycemia, and remains in very good health. A possible future relapse, however, cannot be excluded.

Diabetes mellitus is ordinarily regarded as a permanent, constitutional defect. "Cure" (or recovery) in the sense that pneumonia or typhoid are cured is probably not applicable to diabetes mellitus. Variability, even marked, in the amount of glucose a patient can tolerate without excreting abnormal amounts of glucose in the urine (fluctuation in tolerance) is common in the course of most cases of diabetes.

According to Zubrod, Eversole, and Dana,[8] a remarkable reduction in insulin requirement is frequently found as Kimmelstiel-Wilson's syndrome progresses. Improvement in the symptoms and findings of diabetes mellitus has also been described as following limitation of diet and consequent loss of weight,[9] cirrhosis,[10] extirpation of pheochromocytoma,[11] radiation of the pituitary gland in acromegaly,[12] relief of Cushing's syndrome,[13] control of hyperthyroidism, a large intake of sodium chloride, McCarey's experiment, myxedema,[14] and senescence.[15] Patients have temporarily shown symptoms and signs of diabetes after brain injury, pancreatic disease, or hyperthyroidism. Maintenance of aglycosuria is often rewarded by a marked increase in the ability to tolerate much larger quantities of glucose-yielding food. None of these conditions account for the spontaneous disappearance of the symptoms and signs in our patient.

One of us (E. F. T.) observed a 10-year-old boy with severe, persistent, classic, uncomplicated diabetes mellitus requiring 60 units of insulin for its control who, without apparent cause, lost all the symptoms and signs of diabetes mellitus during an observation of one year. The spontaneous disappearance of the signs and symptoms of diabetes mellitus has been described before. John's first patient,[16] who had acromegaly and ultimately lost all symptoms and signs of diabetes, even to the development of a normal glucose tolerance curve, may be explained as manifesting the Houssay phenomenon[17] due to destruction of the pituitary gland by tumor. Kotte and Vonderahe[18] also described such a case.

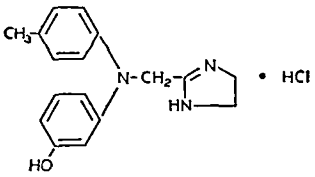
SUMMARY

A 68-year-old woman showing extreme hyperglycemia with profound ketosis and prolonged coma recovered apparently completely from the signs and symptoms of diabetes mellitus. Her diabetes eventually went into spontaneous remission. We have been unable to find a record of a similar case.

715 Lake St. (Dr. Traut).

COUNCIL ON PHARMACY AND CHEMISTRY

Phentolamine Hydrochloride.—Regitine Hydrochloride (Ciba). —$C_{17}H_{19}N_3O.HCl$.—M.W. 317.81.—2-{ [N-(*m*-Hydroxyphenyl)-*p*-toluidino]methyl }-2-imidazoline hydrochloride.—The structural formula of phentolamine hydrochloride may be represented as follows:



Actions and Uses.—Phentolamine hydrochloride, a salt of phentolamine base, is suitable for oral administration and acts as a potent adrenergic blocking agent, producing adrenolytic and sympatholytic effects.

Experimentally, phentolamine blocks the peripheral effects associated with electrical stimulation of sympathetic nerves (sympatholytic action). In comparatively small amounts, it effectively reverses the hypertensive action of injected epinephrine and suppresses the pressor response to levarterenol (adrenolytic action). This antiadrenergic action constitutes the basis for the use of phentolamine salts in the diagnosis and control of hypertension caused by pheochromocytoma and in the treatment of certain vascular diseases in which blood flow to ischemic extremities can be increased by adrenergic blockade. In certain cases the drug has been shown to be beneficial in the treatment of the sequelae of frostbite and immersion foot and has produced favorable responses in other vasospastic conditions, including Raynaud's disease and vasospasm associated with trophic ulcers of the extremities. It has also proved valuable in some patients as an antihypertensive agent, particularly in the management of hypertensive emergencies or as an adjunct in the treatment of chronic arterial hypertension.

Because of its less ready solubility and the temporary stability of aqueous solutions of phentolamine salts, phentolamine hydrochloride (in contrast to phentolamine methanesulfonate) is not suited for parenteral injection, which is necessary in the diagnosis and surgical management of pheochromocytoma. However, phentolamine hydrochloride is useful by the oral route for the control and prevention of blood pressure increases in patients with pheochromocytoma until surgical removal can be undertaken. For parenteral use and dosage of the drug, see the monograph on phentolamine methanesulfonate.

Phentolamine hydrochloride is relatively nontoxic, but oral administration of the drug may produce untoward side-effects, such as tachycardia, orthostatic hypotension, nasal stuffiness, and gastrointestinal disturbances such as nausea, vomiting, and diarrhea. Because of tachycardia, most patients do not tolerate the dosage required for sustained therapy of chronic hypertensive vascular disease. Withdrawal of medication is not always necessary, and, when it is employed in other conditions, a reduction in dosage is frequently followed by a disappearance of untoward symptoms.

Dosage.—Phentolamine hydrochloride is administered orally. The usual adult dose is 50 mg. four to six times daily. Larger doses, as high as 100 mg., four to six times daily, may be necessary, especially in severer cases of peripheral vascular disease and hypertension. In children, the usual dosage is 25 mg. four to six times daily.

Tests and Standards.—

Physical Properties: Phentolamine hydrochloride is a white or slightly off-white, odorless, bitter powder, m.p. 238-242° (with slight decomposition). It is very slightly soluble in chloroform, and practically insoluble in acetone and ethyl acetate. The amounts that dissolve in the following solvents to form 100 ml. of solution are: 0.85 gm. in alcohol and 2 gm. in water. Aqueous solutions of phentolamine hydrochloride are unstable. The pH of the 1% solution is 4.5-5.5.

Identity Tests: Dissolve about 50 mg. of phentolamine hydrochloride in 10 ml. of water, and add 2 drops of nitric acid and 1 ml. of silver nitrate T.S.: a white precipitate forms, which is insoluble in diluted nitric acid, but soluble in a large excess of diluted ammonia solution *(presence of chloride and distinction from phentolamine methanesulfonate).*

Phentolamine trichloroacetate obtained in the chemical assay for phentolamine hydrochloride melts at 136-141°.

A 0.001% solution, prepared as described in the spectrophotometric assay for phentolamine hydrochloride, exhibits an ultraviolet absorption minimum at about 255 mμ and a maximum at about 279 mμ [specific absorbancy, E(1%,1 cm.), about 252].

Purity Tests: Suspend 1 gm. of phentolamine hydrochloride in about 15 ml. of water, filter, and make up to 23 ml. with water poured through the filter. Add 2 ml. of diluted acetic acid and run a U.S.P. heavy metals test: the amount of heavy metals does not exceed 20 ppm.

Dissolve 0.1 gm. of phentolamine hydrochloride in enough water to make 25 ml. of solution, add 1 ml. of barium chloride T.S., shake, and allow the mixture to stand for 1 min.: the turbidity does not exceed that of 0.2 ml. of 0.02 *N* sulfuric acid diluted to 25 ml. and treated in the same manner *(presence of sulfate).*

Dry about 1 gm. of phentolamine hydrochloride, accurately weighed, at 60° in a vacuum for 4 hours: the loss in weight does not exceed 0.5%.

Char about 1 gm. of phentolamine hydrochloride, accurately weighed, cool the residue, add 1 ml. of sulfuric acid, heat cautiously until evolution of sulfur trioxide ceases, ignite, cool, and weigh: the residue does not exceed 0.1%.

Assay: (Phentolamine Hydrochloride) Prepare a 0.001% solution of phentolamine hydrochloride as follows. Transfer to a 100 ml. volumetric flask 0.1 gm. of phentolamine hydrochloride, accurately weighed, fill to the mark with alcohol, and mix. Transfer to a second 100 ml. volumetric flask 10 ml. of this solution, fill to the mark with alcohol, and mix. Transfer to a third 100 ml. volumetric flask 10 ml. of this last solution, fill to the mark with alcohol, and mix. Spectrophotometrically determine the absorbancy in a 1 cm. quartz cell at 279 mμ, using alcohol as a blank. The concentration of phentolamine hydrochloride in the solution in mg./ml. = absorbancy ÷ 25.2. The amount of phentolamine hydrochloride is not less than 95.0 nor more than 105.0%.

Transfer to a 100 ml. beaker about 0.1 gm. of phentolamine hydrochloride, accurately weighed. Dissolve the powder in 15 ml. of water. Add slowly, while stirring, 20 ml. of clear 10% trichloroacetic acid, and let the beaker stand for at least 1 hour. Suction filter the precipitate through a tared sintered glass crucible, removing any precipitate which adheres to the beaker with three 5 ml. portions of 10% trichloroacetic acid. Wash the precipitate with five 2 ml. portions of water, dry the precipitate in a vacuum over phosphorus pentoxide for 4 hours, and weigh. Each gram of phentolamine trichloroacetate formed is equivalent to 0.7146 gm. of phentolamine hydrochloride. The amount of phentolamine hydrochloride is not less than 98.0 nor more than 102.0%.

Dosage Forms of Phentolamine Hydrochloride

TABLETS. *Identity Tests:* Grind a number of tablets equivalent to about 0.4 gm. of phentolamine hydrochloride and triturate the powder with three 25 ml. portions of alcohol. Filter the alcohol extracts and evaporate the filtrate to dryness on a steam bath. The residue responds to the identity tests for the active ingredient in the monograph for phentolamine hydrochloride.

Assay: (Phentolamine Hydrochloride) Weigh 20 tablets and powder them. Transfer to a 100 ml. volumetric flask an amount of powder, accurately weighed, equivalent to about 0.1 gm. of phentolamine hydrochloride, add 50 ml. of alcohol, and shake the flask mechanically for 15 min. Fill to the mark with alcohol, mix, and centrifuge. Transfer to a second 100 ml. volumetric flask 10 ml. of the clear supernatant liquid, fill to the mark with alcohol, and mix. Transfer to a third 100 ml. volumetric flask 10 ml. of this last solution, fill to the mark with alcohol, and mix. Spectrophotometrically determine the absorbancy in a 1 cm. quartz cell at 279 mμ, using alcohol as a blank. The concentration of phentolamine hydrochloride in the solution in mg./ml. = absorbancy ÷ 25.2. The amount of phentolamine hydrochloride is not less than 93.0 nor more than 107.0% of the labeled amount.

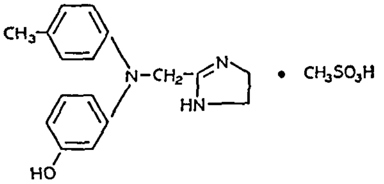
Tablets Regitine Hydrochloride: 50 mg. U. S. patent 2,503,059.

Phentolamine Methanesulfonate.—Regitine Methanesulfonate (Ciba).—$C_{17}H_{19}N_3O.CH_4O_3S$.—M.W. 377.45.—2-{[N-(*m*-Hydroxyphenyl)-*p*-toluidino]methyl}-2-imidazoline methanesulfonate.—The structural formula of phentolamine methanesulfonate may be represented as follows:



Actions and Uses.—Phentolamine methanesulfonate, readily water-soluble salt of the adrenergic blocking agent phentolamine base, exhibits adrenolytic and sympatholytic effects. The methanesulfonate salt is used for parenteral injection in the diagnosis and surgical management of hypertension caused by pheochromocytoma, a tumor that characteristically gives rise to excessive circulating epinephrine and/or levarterenol (*l*-norepinephrine). Phentolamine, as the hydrochloride salt, is administered orally to control blood pressure increases in patients with pheochromocytoma until surgical removal can be undertaken. For other uses and the dosage of the orally administered hydrochloride salt, see the monograph on phentolamine hydrochloride.

Phentolamine effectively blocks the pressor activity of epinephrine and levarterenol for longer periods than does piperoxan, and in smaller amounts. Therefore, phentolamine methanesulfonate is considered more useful and less toxic than piperoxan as a diagnostic agent to exclude the presence of pheochromocytoma as a cause of paroxysmal or persistent hypertension. On the other hand, piperoxan is less likely to cause a misleading drop in blood pressure in ordinary cases of hypertension. It should, therefore, be employed as a confirmatory test when interpretation of the results is in doubt.

The use of phentolamine methanesulfonate as a diagnostic test for pheochromocytoma is based on its adrenolytic effect in producing a fall in blood pressure during a "typical" paroxysmal hypertensive episode. However, it is also indicated diagnostically in the presence of persistent chronic hypertension, especially when the hypertension is associated with a high basal metabolic rate, hyperglycemia, and tachycardia, and in sudden severe hypertension in a normotensive or hypertensive patient during anesthesia or operative procedure, and in hypertension in children or young adults, especially in the absence of severe renal disease. During the normotensive phase, that is, when the pheochromocytoma is not discharging sufficient epinephrine or levarterenol to elevate the blood pressure or to sustain an elevation, and in essential hypertension coexisting with a pheochromocytoma, repeated testing may be necessary to rule out "false negative" interpretation of a slight fall in blood pressure following administration of phentolamine.

A "false positive" drop in pressure may occur in patients with uremia and in those who have received sedatives prior to the test with phentolamine. Therefore, the test should be performed in the absence of sedation (or any anodyne) for at least 24 hours preceding. Basal blood pressure is first determined following a period of rest in the supine position and the injection of the agent is delayed after introduction of the needle to allow the hypertensive effect of needle pain to subside.

The duration of the blood pressure response to phentolamine is influenced by the route of injection. Moderate or slight tachycardia is the only undesirable side-effect of the test so far associated with intramuscular injection of the recommended dose. Given intravenously, the same dose has caused tachycardia with angina and in rare instances, weakness, dizziness, or flushing, none of which have been considered serious. The diagnostic and therapeutic use of phentolamine methanesulfonate in pheochromocytoma is considered to be relatively safe and free from alarming reactions.

Dosage.—Phentolamine methanesulfonate is employed in permanently stable, lyophilized form for preparation of a fresh aqueous solution for administration by intramuscular or intravenous injection. In solution, phentolamine salts are stable for only about six months. For adults, the intramuscular or intravenous test dose is 5 mg. in 1 cc. of distilled water for injection; in children an intramuscular dose of 3 mg. or an intravenous dose of 1 mg. is usually adequate. A typical positive response is characterized by an immediate drop in systolic and diastolic blood pressure. The maximum depressor effect is usually obtained within 2 minutes after intravenous injection and within 20 minutes after intramuscular injection. Generally, the systolic fall is approximately 60 mm. Hg, with the diastolic fall exceeding 25 mm. Hg, but the degree of response may be somewhat less in some patients. After intramuscular injection, the reduction usually persists for some 30 minutes and gradually returns to previous levels within 3 to 4 hours. After intravenous administration, the blood pressure usually returns to previous levels within 10 to 15 minutes and occasionally within 2½ minutes. Negative responses are recorded when there is no change in blood pressure, a slight or moderate rise in blood pressure, or only a slight lowering of blood pressure. The intravenous route should be employed if it is necessary to repeat the test to rule out false reactions.

In the control of blood pressure during surgical management of pheochromocytoma, the preoperative adult dose is 5 mg., intramuscularly or intravenously, one to two hours before the operation. This is repeated, if necessary, to prevent a paroxysm caused by anesthesia or emotional stress. For children, the preoperative dose is 3 mg. intramuscularly or 1 mg. intravenously. During operation, an intravenous dose of 5 mg. for adults or 1 mg. for children, repeated if necessary, may be given whenever blood pressure begins to rise as a result of stress or of manipulation of the tumor.

Tests and Standards.—

Physical Properties: Phentolamine methanesulfonate is a white, odorless, bitter powder, m.p. 175-180°. It is freely soluble in water, very slightly soluble in acetone, and practically insoluble in ethyl acetate. The amounts that dissolve in the following solvents to form 100 ml. of solution are: 6.8 gm. in alcohol and 0.15 gm. in chloroform. Phentolamine methanesulfonate is stable when protected from moisture. The pH of the 1% solution is 4.5-5.5.

Identity Tests: Heat about 50 mg. of phentolamine methanesulfonate in a small test tube with a pellet of sodium hydroxide until the mixture just melts. Cool, dissolve the melt in 2 drops of water, and add 2 drops of hydrochloric acid. Wash the walls of the test tube with 5 drops of water, wipe dry the rim of the tube, and lay over the mouth a strip of filter paper *impregnated with nickelous hydroxide (dip paper in 30% nickelous* chloride and then in 10% sodium hydroxide). Immerse the test tube in water at about 80°: the paper turns from light green to black or gray *(presence of sulfonic acid group and distinction from phentolamine hydrochloride).*

Phentolamine trichloroacetate obtained in the chemical assay for phentolamine methanesulfonate melts at 136-141°.

A 0.001% solution, prepared as described in the spectrophotometric assay for phentolamine methanesulfonate, exhibits an ultraviolet absorption minimum at about 256 mμ and a maximum at about 280 mμ [specific absorbancy, E(1%,1 cm.), about 212].

Purity Tests: Dissolve 1 gm. of phentolamine methanesulfonate in 23 ml. of water, add 2 ml. of diluted acetic acid, and run a U.S.P. heavy metals test: the amount of heavy metals does not exceed 20 ppm.

Dissolve 0.1 gm. of phentolamine methanesulfonate in enough water to *make 25 ml. of solution, add 1 ml. of barium chloride T.S., shake, and* allow the mixture to stand for 1 min.: the turbidity does not exceed that of 0.2 ml. of 0.02 *N* sulfuric acid diluted to 25 ml. and treated in the same manner *(presence of sulfate).*

Dry about 1 gm. of phentolamine methanesulfonate, accurately weighed, at 60° in a vacuum for 4 hours: the loss in weight does not exceed 0.5%.

Char about 1 gm. of phentolamine methanesulfonate, accurately weighed, cool the residue, add 1 ml. of sulfuric acid, heat cautiously until evolution of sulfur trioxide ceases, ignite, cool, and weigh: the residue does not exceed 0.1%.

Assay: (Phentolamine Methanesulfonate) Prepare a 0.001% solution of phentolamine methanesulfonate as follows. Transfer to a 100 ml. volumetric flask 0.1 gm. of phentolamine methanesulfonate, accurately weighed, fill to the mark with alcohol, and mix. Transfer to a second 100 ml. volumetric flask 10 ml. of this solution, fill to the mark with alcohol, and mix. Transfer to a third 100 ml. volumetric flask 10 ml. of this last solution, fill to the mark with alcohol, and mix. Spectrophotometrically determine the absorbancy in a 1 cm. quartz cell at 280 mμ, using alcohol as a blank. The concentration of phentolamine methanesulfonate in the solution in mg./ml. = absorbancy ÷ 21.2. The amount of phentolamine methanesulfonate is not less than 95.0 nor more than 105.0%.

Transfer to a 100 ml. beaker about 0.1 gm. of phentolamine methanesulfonate, accurately weighed. Dissolve the powder in 15 ml. of water. Add slowly, while stirring, 20 ml. of clear 10% tricholoroacetic acid, and let the beaker stand for at least 1 hour. Suction filter the precipitate of phentolamine trichloroacetate through a tared sintered glass crucible, removing any precipitate which adheres to the beaker with three 5 ml. *portions of 10% trichloroacetic acid. Wash the precipitate with five 2 ml.* portions of water, dry the precipitate in a vacuum over phosphorus pentoxide for 4 hours, and weigh. Each gram of phentolamine trichloroacetate formed is equivalent to 0.8487 gm. of phentolamine methanesulfonate. The amount of phentolamine methanesulfonate is not less than 98.0 nor more than 102.0%.

Dosage Forms of Phentolamine Methanesulfonate

POWDER. *Physical Properties:* The lyophilized powder has the same physical properties as are given for the active ingredient in the monograph for phentolamine methanesulfonate, but the powder consists of small needles that are more readily soluble.

Identity Tests: The powder responds to the identity tests for the active ingredient in the monograph for phentolamine methanesulfonate.

Assay: (Phentolamine Methanesulfonate) Transfer to a 100 ml. volumetric flask 0.1 gm. of the powder, accurately weighed, fill to the mark with alcohol, and mix. Proceed as directed in the spectrophotometric assay for phentolamine methanesulfonate in the monograph for phentolamine methanesulfonate starting with "Transfer to a second 100 ml. volumetric flask . . ." The concentration of phentolamine methanesulfonate in the solution in mg./ml. = absorbancy ÷ 21.2. The amount of phentolamine methanesulfonate is not less than 95.0 nor more than 105.0% of the labeled amount.

Ciba Pharmaceutical Products, Inc., Summit, N. J.

Lyophilized Regitine Methanesulfonate: 5 mg. ampuls. Each ampul contains 5 mg. of phentolamine methanesulfonate. Packaged with 1 cc. vial of water for injection. U. S. patent 2,503,059.

Tetracaine Hydrochloride-U.S.P. (See New and Nonofficial Remedies 1953, p. 41).

Winthrop-Stearns Inc., New York.

Solution Pontocaine Hydrochloride 0.2% with Dextrose 6% (For Saddle Block Anesthesia): 2 cc. ampuls. A hyperbaric solution containing 2 mg. of tetracaine hydrochloride in each cubic centimeter.

Solution Pontocaine Hydrochloride 0.3% with Dextrose 6% (For Spinal Anesthesia): 5 cc. ampuls. A hyperbaric solution containing 3 mg. of tetracaine hydrochloride in each cubic centimeter.

COUNCIL ON FOODS AND NUTRITION

ACCEPTED FOODS

In order to encourage the production of fruit juices containing high natural levels of vitamin C, the Council on Foods and Nutrition accepts canned tomato juice in which there is at least 17.5 mg. of ascorbic acid per 100 ml. at the time of packing.

The following product has been accepted by the Council and permission to use the seal has been granted.

JAMES R. WILSON, M.D., *Secretary.*

Aslesen Company, Minneapolis.

Banquet Table Brand Tomato Juice.

This product is vacuum packed in 7 oz., 46 oz. and #10 size containers. The vitamin C content averaged 24.0 mg. per 100 ml. for the 1952 packing season.

SURGICAL TREATMENT OF BRONCHIECTASIS

Laennec in 1819 described bronchiectasis as a clinical and pathological entity. Bronchography with the aid of iodized oil, introduced by Sicard and Forestier, added more precise knowledge of the disease in the past two decades. The condition is recognized today as a common chronic pulmonary disease, being more commonly observed than pulmonary tuberculosis. As a result of repeated attacks of bronchopneumonia, usually in childhood, chronic inflammatory changes develop in the bronchial mucosa and submucosa. These changes may lead to a state of extensive irreversible fibrosis of a segment or of an entire lobe, weakening of the bronchial wall, and stenosis of bronchi, with dilatation distal to the stenosis. Stagnation of purulent secretion, often containing anaerobic and aerobic micro-organisms, occurs in the ectatic areas distal to the stenosis. Fibrosis of parenchyma and compensatory emphysema develop.

Symptoms are those of a chronic cough, productive of purulent sputum. There may be hemoptysis, chest pain, recurrent attacks of pneumonia or of bronchopneumonia, dyspnea, chronic sepsis, and invalidism. In addition to standard roentgenograms of the chest, bronchography is essential for a definite diagnosis. Medical treatment of bronchiectasis is directed toward mechanical drainage, control of infection, and measures to improve the general health. Postural drainage is probably the most important single mechanical procedure for emptying the dependent bronchiectatic cavities of their secretions. Bronchoscopy is useful for the removal of unsuspected foreign bodies and for the diagnosis of primary bronchogenic carcinoma, which is often masked by bronchiectasis. Segmental location of the disease within the lung may also be aided by bronchoscopy. Its value in the treatment is at best palliative. Chemotherapy and antibiotics aid in the suppression of sensitive micro-organisms. Sinusitis usually develops in the course of the disease and serves to aggravate the condition by giving rise to repeated infection. It is not an etiological factor in bronchiectasis.

The survey by Perry and King[1] of 400 patients indicates the poor prognosis of patients treated medically. The irreversible lesions of bronchiectasis cannot be influenced by medical management, even though it may contribute greatly to the comfort of the patient. Chronic invalidism beginning in childhood, continuing throughout life, and characterized by mental lethargy and ineptitude, physical unfitness, and social maladjustment is the inevitable picture of any untreated or unsuccessfully treated case of bronchiectasis.

Today the consensus is that bronchiectasis can be cured only by a resection of the diseased segments of the lung. Brunn[2] in 1929 reported six one-stage lobectomies with one death. An important advance was the introduction by Churchill and Belsey[3] of the technique of segmental resection. Overholt and Langer[4] (1947) emphasized that the characteristic distribution of lesions in bronchiectasis is segmental. The removal of the segment presents no undue technical difficulties or risk. Segmental resection not only eradicates all the diseased tissue but also eliminates the necessity of sacrificing the uninvolved segments. This approach to the problem, according to Overholt and Langer, permits the accomplishment of two fundamental principles of surgery: (1) cure of the patient and (2) preservation of as much functional tissue as possible. Bronchiectasis is primarily a segmental disease and is frequently bilateral, usually involving certain pulmonary segments within the lobe rather than an entire lobe.

In 1947 Kay[5] reported 220 consecutive lobectomies with only one operative death. Ochsner and his co-workers[6] reported in 1949 on 92 operations without a single hospital fatality. Subsequent death from pulmonary disease has occurred in 3.1% of their cases. Unsatisfactory results were recorded in 4.2%. In a recent communication Storey and Laforet[7] report 100 resections performed on 92 patients. They emphasize that the great advance in the surgical therapy of bronchiectasis has been accomplished by adoption of the policy of limiting the resection to the involved segments, to the employment of individual hilar dissection, and to ligation technique. They also stress the necessity of bronchography to obtain a complete mapping of the tracheobronchial tree. In their series of patients the most frequently resected areas were the lingula of the left upper lobe, the right middle lobe, and the base segments of the lower lobe of both lungs. This appears to be the universally accepted distribution of bronchiectasis. The

more localized the disease the better the expectation of complete extirpation with a curative or greatly beneficial result. The very young withstand major intrathoracic surgery remarkably well. There were two fatalities in Storey and Laforet's series of 100 resections. Of the 70 patients who were followed up for over six months or longer, the results were classified as excellent in 51 (73%), good in 12 (17%), fair in 4 (6%), and poor in 3 (4%).

Cure of bronchiectatic disease of the lung may be reasonably expected from resection, provided the disease is not too extensive, the patient is not elderly, and there exist no definite conditions contraindicating a major surgical intervention.

FOOD AND PREVENTIVE MEDICINE

The recently published paper by Conrad A. Elvehjem[1] on the importance of food in preventive medicine reveals clearly the need for applying adequate nutritional standards to all populations. Nutrition has become so important that it cannot be regarded casually; on the contrary, it must always be remembered in most, if not all, thorough diagnostic and therapeutic procedures. Today one can even speak of food therapy, since the word food embraces such a broad field, since food has been broken down into many substances, and since these substances can be applied specifically for treatment as well as for the prevention of nutritional disorders. In fact, they are often used in what at first seem to be unrelated health problems; however, further study would reveal the reasons for such therapy and at the same time would indicate the complexity and scope of modern nutritional practices.

Nutritional deficiency cannot be regarded, as was the situation some years ago, as being present only when such diseases as pellagra, beriberi, and scurvy are diagnosed. Not too long ago it was popular to speak of borderline deficiencies, but even this description seems to have outlived its usefulness. Elvehjem speaks of "conditioned deficiencies" and mentions diabetes mellitus, colitis, peptic ulcers, and anemia as health problems in which there is need to take an extra long look at the possibility of there being a deviation from the optimum nutrition. Also of special importance in this field are the diseases in which fever plays a prominent part. During fever there is an increased demand on some nutrients because of increased metabolism. At the same time, there is increased destruction of body tissues, loss of nitrogen, and perhaps a disturbance of the water balance. Of similar concern are diseases of the gastrointestinal tract, when absorption as well as utilization of nutrients must be considered. Thus one must be concerned not only with the likes and dislikes of the sick person in regard to nutrition but also with the requirements peculiar to his condition.

Like other researchers in the field of nutrition, such as W. C. Rose, Elvehjem has been especially interested in amino acids and also in enzymes. Some of his work reveals the interrelation of enzymes of the liver, amino acids, and disease. From it has come a practical point for immediate application in the relation between physician and patient. Elvehjem states in part: ". . . diseased conditions may result either suddenly or after long delayed periods. . . . these changes can be aggravated by an imbalance of amino acids which again emphasizes the importance of supplying amino acids in foods rather than in combinations which may be quite different than those usually encountered in food materials. . . . experimental findings indicate that the amino acids, in at least our most common protein foods, are readily released." Such information should guide the physician, who ought to warn his patients against unnecessary and possibly dangerous self-prescribing of vitamins, protein supplements, and amino acid preparations.

Partly on the basis of personal experiments on laboratory animals, Elvehjem warns of the health problems that may arise in later life when there are changes in metabolism during infancy. At the other end of the life span are the nutritional problems associated with geriatrics, about which much has been learned but even more remains to be discovered. Both Elvehjem and Ancel Keys have commented particularly on one phase of this. Keys has said: "Part of the problem of providing nutritional help for older persons consists in countering the claims of food faddists, the purveyors of special nostrums offered for nutritional purposes, and the writers who find the ready sale for books and articles promising miracles from peculiar diets." Elvehjem stresses this portion of the nutrition field by stating: "The worst enemy is the group of food faddists and the most vicious of these are the individuals who, by one method or another, place the M. D. after their name." Unquestionably related and of the same health significance are the so-called reducing diets, which may be causing disturbances that will be reflected in succeeding generations. Such diets, especially when they result in a high intake of one kind of food and the suboptimal intake of others, may prove subsequently to be harmful.

It is obvious that there is much to learn about nutrition, but this does not mean that that which already is known should not be applied now. There has been extended comment in recent years about health education. Many have been active in urging the adoption of healthful nutritional practices and the rejection of those that are harmful. In the field of nutrition there are excellent opportunities for all interested persons to apply one of the sound principles of health education—optimum nutrition. This is a wide field with many interesting aspects, but there should be no hesitation about applying immediately what already is known to be best for the population.

ORGANIZATION SECTION

FEDERAL MEDICAL LEGISLATION

Vocational Rehabilitation for the Blind

Senator Potter (R., Mich.) has introduced a bill, S. 2436, to amend the Vocational Rehabilitation Act at the request of the National Rehabilitation Association. This bill would include the following important additions to this federal law. 1. It defines blindness, providing for certification by physicians skilled in diseases of the eye. 2. It permits the use of federal funds for the purchase of stocks of goods for business ventures for disabled persons generally. 3. Federal funds could be expended to pay for the supervision of work of the disabled and to finance their training, demonstrations, research, and fellowships, and to help in working out marketing arrangements. 4. It would allow federal payments to states whose programs of hospitalization exceed the 90 day limit. 5. It authorizes those state agencies for the blind that operate separately from other state rehabilitation agencies to deal directly with the Federal Office of Vocational Rehabilitation. 6. The title of the Office of Vocational Rehabilitation would be changed to Bureau of Vocational Rehabilitation and would continue in the Department of Health, Education, and Welfare. This bill is identical with H. R. 5562 (Rhodes) and H. R. 5610 (Williams), both previously reported. This measure was referred to the Labor and Public Welfare Committee.

Additional Vocational Rehabilitation Legislation

Senator Potter (R., Mich.) has introduced S. 2437 at the request of the National Rehabilitation Association. This bill would further amend the National Rehabilitation Act to authorize federal grants to the states for the establishment of rehabilitation centers to provide physical and occupational therapy, vocational or exploratory vocational training, testing, fitting or training in use of prosthetic devices, and adjustment training and evaluation or control of special disabilities. This bill would also allow the use of federal funds to establish workshops in which remunerative employment could be provided to severely disabled persons who cannot be absorbed in the competitive labor market under the direction of a public or private nonprofit agency. In each case the federal share of the cost would range from one-third to two-thirds, depending on the per capita wealth of the state. This measure is identical with H. R. 5563 (Rhodes) and H. R. 5609 (Williams), previously reported. This bill was referred to the Labor and Public Welfare Committee.

Knowland Compromise for Bricker Constitutional Amendment

Senator Knowland (R., Calif.) in the substitute S. J. Res. 1 offers a compromise for the Bricker Constitutional Amendment. President Eisenhower has endorsed Knowland's substitute, the text of which is as follows:

"Section 1. A provision of a treaty or other international agreement which conflicts with the Constitution shall not be of any force or effect. The judicial power of the United States shall extend to all cases, in law or equity, in which it is claimed that the conflict described in this amendment is present.

"Sec. 2. When the Senate consents to the ratification of a treaty the vote shall be determined by yeas and nays, and the names of the persons voting for and against shall be entered on the Journal of the Senate.

"Sec. 3. When the Senate so provides in its consent to ratification, a treaty shall become effective as internal law in the United States only through the enactment of appropriate legislation by the Congress.

"Sec. 4. This article shall be inoperative unless it shall have been ratified as an amendment to the Constitution by the legislatures of three-fourths of the several states within seven years from the date of its submission."

Public Assistance

Congressman Bennett (D., Fla.) has introduced a measure, H. R. 6505, which would change the formula used in computing the federal share of state public assistance programs. The federal contributions now for aged, blind, and permanently and totally disabled are four-fifths of the first $25 and one-half of an additional $30 in public assistance programs. The Bennett bill would raise the federal share to five-sixths of the first $30 and one-half of an additional $30. The present federal contributions to programs for aid to dependent children are four-fifths of the first $15 for the first child and one-half of an additional $15. For each additional child the federal contribution is four-fifths of the first $15 and one-half of an additional $6. Congressman Bennett in H. R. 6505 would make the federal contribution five-sixths of the first $18 and one-half of an additional $15 for the first child; for each additional child the federal share would be five-sixths of the first $18 and one-half of an additional $6. The measure was referred to the Ways and Means Committee.

Leprosy

Congressman Thompson (D., La.) has introduced a bill, H. R. 6285, which is identical with S. 1584, introduced by Senator Murray and previously reported. Congressman Thompson proposes that the U. S. Public Health Service take the lead in a drive against leprosy by (1) an information campaign, (2) construction of five additional leprosariums, (3) provision of treatment methods for veteran patients in VA hospitals and nonveterans in other hospitals, (4) establishment of rehabilitation and reemployment programs for discharged leprosy patients, and the selection of and arrangement with private physicians to treat leprosy patients at home, (5) money allowances for patients in federal leprosariums and treatment centers and for dependents of such patients, and (6) authorization of additional funds for research. This measure was referred to the Interstate and Foreign Commerce Committee.

Broadening Social Security

Congressman O'Brien (D., Mich.) has introduced a bill, H. R. 6320, which would broadly revise the old age and survivors insurance system in a number of ways, including the extension of coverage to a number of groups not now covered, increasing the portion of wages subject to tax and increasing monthly dollar benefits and the amount a retired person under 75 could earn in a month without suspension of his benefit payments. Provision would be made for retirement benefits for permanently and totally disabled persons, and cash sickness insurance would be provided for persons temporarily disabled. This bill is identical with S. 2260, introduced by Senator Lehman, and approximately 20 other previously reported bills. The measure was referred to the Ways and Means Committee.

Prepared by the Bureau of Legal Medicine and Legislation.

RECENT A. M. A. PUBLICATIONS

A Doctor for Your Community, containing suggestions for the use of communities in obtaining physicians for their areas. Prepared by the Council on Medical Service.

National Conference on Rural Health, a pamphlet containing a digest of the proceedings of the eighth National Conference on Rural Health, held at Roanoke, Va., in February, 1953. Prepared by the Council on Rural Health.

Quarterly Cumulative Index Medicus, volume 50, which covers the literature for the last half of 1951, is now off the press and available for purchase from the Order Department of the American Medical Association. The next volume is in production and should be completed by the end of the year.

MEDICAL NEWS

CALIFORNIA

Research on Leukemia.—Dr. Alfred Goldman, chief of professional services, announces a special project for research on leukemia at the City of Hope, Duarte. The leukemia unit, which operates as part of the tumor hospital, includes hospital beds and facilities for research in the cancer research institute. A leukemia committee, set up to administer the project, includes Dr. Fred S. Preuss, Duarte, director, department of pathology; Dr. Riojun Kinosita, director, cancer research institute; Dr. Aaron F. Rasmussen, City of Hope consultant in virology and professor of infectious diseases at the University of California at Los Angeles; and Dr. Hermann Karl Sachs, director, City of Hope tumor hospital and clinics.

COLORADO

Dr. Busse Heads Department at Duke.—Dr. Ewald W. Busse, chief, division of psychosomatic medicine, Colorado General Hospital, Denver, has been appointed chairman of the psychiatric department of Duke University School of Medicine, Durham, N. C. Dr. Busse, who has been at the Colorado University Medical Center since 1946, heads the mental hygiene and child guidance clinic and directs the electroencephalograph laboratory. He will assume his new post Nov. 1.

Cancer Seminar at the Broadmoor.—The fifth annual cancer seminar, sponsored by the Penrose Cancer Hospital and the American College of Pathologists, will be held at the Broadmoor Hotel, Colorado Springs, Sept. 5. The subject of the seminar will be "Lesions of the Small Bowel." Dr. Paul C. Swenson, professor of radiology, Jefferson Medical College of Philadelphia, will be guest radiologist and Dr. William A. Meissner of the New England Deaconess Hospital, Boston, guest pathologist. The guest of honor will be Dr. Harry M. Weber of the Mayo Foundation, Rochester, Minn.

DISTRICT OF COLUMBIA

Society News.—The Washington Academy of Surgery has elected Dr. George K. Nutting, president; Dr. W. Ross Morris, vice-president; and Dr. Duane C. Richtmeyer, secretary-treasurer.

University News.—The following members of the faculty of George Washington University School of Medicine, Washington, D. C., each having given 25 years of teaching service to the university, were honored by the University Alumni Association at a luncheon in Washington, where each was presented with a scroll: Dr. Walter A. Bloedorn, dean of the school of medicine; Dr. Harry F. Anderson, professor of dermatology and syphilology; Dr. Laurence L. Cockerille, assistant clinical professor of obstetrics and gynecology; Dr. Daniel B. Moffett, professor of otolaryngology; Dr. Maurice Protas, associate in medicine; and Dr. Herbert P. Ramsey, clinical professor of obstetrics and gynecology.

Personal.—Dr. John B. Barnwell, chief, Tuberculosis Division of the Veterans Administration in Washington, D. C., since 1946, recently received from his alma mater, Trinity College, Hartford, Conn., an honorary degree of doctor of science.——Dr. Thomas S. Lee, Washington, D. C., permanent honorary president of the Washington Heart Association, which he founded in 1927, recently received a medal and High Citation certificate from the American Legion for his work with the Washington Heart Association.——Dr. Jonathan M. Williams, Washington, D. C., was recently elected to honorary membership in the Medical Society of the Dominican Republic. Presentation of the diploma was made at a buffet supper at the embassy of the Dominican Republic.——Dr. Brian B. Blades, since 1946 head of the surgical department of George Washington University Hospital, Washington, D. C., received a citation for distinguished service from the University of Kansas Alumni Association during commencement exercises in Lawrence, Kan. The citation, made on the basis of his "contribution to mankind," mentioned his service during World War II in helping to establish chest clinics in Army general hospitals and his work in developing the operation for relief of intractible asthma. Dr. Blades was chief of the thoracic surgery section of the Walter Reed Army Hospital and consultant to the Surgeon General during World War II.

ILLINOIS

Committee for Crippled Children.—The University of Illinois board of trustees has appointed the following as members of the Professional Advisory Committee of the Division of Services for Crippled Children: Drs. Floyd S. Barringer, Springfield, Gerald M. Cline, Bloomington, Francis L. Lederer, Chicago, John H. Mathis and Robert B. Rutherford, Peoria, and Lawrence D. Ruttle, Joliet.

Personal.—Dr. John D. Scouller, Pontiac, Dr. Christian H. Zoller, Litchfield, and Dr. George F. Blough, Odell, were recently awarded 50 year membership certificates by the Illinois State Medical Society.——Dr. Roland I. Pritikin, Rockford, attended the seventh International Congress of the History of Science, Jerusalem, Israel, Aug. 3-7, as official delegate or observer for a number of American, Western Hemisphere, and international medical societies.

Chicago

Dr. Campbell Made Acting Superintendent.—Dr. Duncan D. Campbell, assistant superintendent, Chicago State Hospital, has been made acting superintendent. Dr. Campbell has been affiliated with the hospital since 1946. He formerly served as superintendent of the Missouri State Hospital, St. Joseph, and clinical director and manager of Veterans Administration and mental hospitals in Iowa, Maryland, and Arkansas.

Blatt Memorial Lecture.—The pediatric staff of Cook County Hospital announces that the annual Morris Lamm Blatt Memorial Fund lecture will be given Oct. 26 in conjunction with the Dr. Julian D. Levinson Research Foundation. Dr. Milton G. Bohrod, director, clinical and pathological laboratories, Rochester (N. Y.) General Hospital, will speak on pathology of allergy at 8:30 p. m. in the medical amphitheater of Cook County Hospital.

KENTUCKY

Doctor Reynolds Day.—In recognition of his more than 50 years of service as a general practitioner in Carlisle, the community honored Dr. Benjamin F. Reynolds at a special father's day program in the Christian Church and at a dinner given by Dr. Eslie Asbury, Cincinnati, at his Forest Retreat Farm. Dr. Reynolds was further honored at the alumni luncheon of his alma mater, the University of Louisville School of Medicine, where he was awarded a 50 year diploma.

Society News.—Some 30 physician members of the Committee on Emergency Medical Service of the Kentucky State Medical Association and its subcommittees recently spent a day in Louisville, planning ways to provide adequate medical care for major emergencies.——A long service ended recently when Drs. Herbert G. Davis, Marrowbone, and William F. Owsley, Burkesville, resigned as president and secretary, respectively, of the Cumberland County Medical Society and were succeeded by Drs. Joseph Schickel and William F. Boyer of

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

Burkesville.——At a joint meeting in Louisville, committees of the Kentucky State Dental Association and the Kentucky State Medical Association approved a program to promote further improvements in dentist-physician relationships and public service.——Dr. Guthrie Y. Graves, Bowling Green, vice-president from Western Kentucky, was elected president of the Kentucky State Medical Association at a recent meeting of its council. Dr. Graves will fill the vacancy created by the death on May 5 of Dr. R. Haynes Barr, Owensboro, until after the next annual meeting in September, when officers elected at last year's meeeting will be installed.

LOUISIANA

Dr. Albert Dent Honored.—Albert W. Dent, LL.D., president of Dillard University, New Orleans, has been elected president of the National Health Council. Dr. Dent became president of the university in 1941 after 6 years as superintendent of the Flint-Goodridge Hospital of Dillard University. He served as a delegate to the first World Health Assembly at Geneva in 1948 and was vice-president of the National Tuberculosis Association in 1949 and 1950. He is a member of the committee on faculty fellowships of the Ford Fund for the Advancement of Education.

University News.—Tulane University of Louisiana School of Medicine, New Orleans, recently received $12,000 from the Louisiana chapter of the Arthritis and Rheumatism Foundation to support a program of research and clinical studies. Dr. Thomas E. Weiss and Maridel Saunders, instructors in medicine, will conduct the work.——Rufus C. Harris, LL.D., president of Tulane University of Louisiana School of Medicine, New Orleans, has announced the following promotions: (1) to associate professor—Dr. Guillermo M. Carrera, tropical medicine and pathology; Henry E. King, Ph.D., psychiatry and psychology; Dr. Edgar H. Little, clinical radiology; and Dr. Russell Monroe, psychiatry; and (2) to assistant professor—Dr. John H. Dent, pathology; Drs. Norman Hunt and Sam A. Threefoot, medicine; Dr. Rodney C. Jung, tropical medicine; Dr. Kenneth H. Beach, clinical psychiatry; Dr. George D. Berkett, orthopedics; Drs. Joseph K. Bradford, Carl Nadler Jr., and John R. Powers, clinical medicine; Dr. Edward T. Krementz, surgery; Dr. John R. Mitchell, pediatrics; and Dr. David W. Von Gelder, clinical pediatrics.

MICHIGAN

Hospital News.—The Evangelical Deaconess Hospital in Detroit recently honored three staff physicians for a combined medical practice of 151 years. Scrolls were presented at a dinner in the Lochmoor Country Club, Grosse Pointe, to Drs. Charles W. Knaggs, Rudolph L. Pfeiffer, and Mortimer E. Danforth.

Seminars in Industrial Medicine.—The Detroit Industrial Physicians' Club, in cooperation with the faculty of Wayne University College of Medicine, Detroit, recently presented its second series of seminars in industrial medicine for undergraduate students. Two of the seminars were held at the college, where Gordon H. Scott, Ph.D., dean, served as chairman, and two were held on company premises. Dr. Henry S. Brown, Detroit, acted as host at the Michigan Bell Telephone Company and Dr. John H. Ganschow, Detroit, at the Chevrolet Gear and Axle Division of General Motors. Detroit physicians presented the following program: "Definition and Historical Development of Industrial Medicine," Alfred H. Whittaker; "Trauma to the Extremities and Rehabilitation Thereof," Charles G. Johnston; "Advantages of Industrial Medicine as a Specialty," Peter B. Rastello; "Accident Proneness and Accident Prevention," Henry S. Brown; "Neuropsychiatric Problems as Seen by the Industrial Physician," Gordon A. Eadie; "Cooperation Between Private Practitioner and Industrial Physician," William J. Fulton; "Clinical Problems of Tuberculosis and Pneumoconiosis" and "Control of Dusts," Frank J. Jarsen; "On the Job Management of Cardiacs and Hypertensives," Earle A. Irvin; "Health Insurance and Retirement Benefits," Charles J. Clark; "Plumbism and Its Control," Arlington F. Lecklider; "Occupational Skin Irritants and Dermatoses," Loren W. Shaffer; "Administration and Operation of Industrial Medical Programs," Earl F. Lutz; and "Rehabilitation of the Injured Worker," Lyndle R. Martin. Mr. J. C. Radcliffe discussed "Working Conditions and the Control of Health Hazards."

Personal.—Dr. Thomas Francis Jr., Ann Arbor, was recently awarded the James D. Bruce memorial medal by the American College of Physicians for his research work in various diseases.——Dr. Samuel A. Butler, senior physician, Pontiac State Hospital, was recently honored at a testimonial dinner after announcing his intention to retire after 44 years of service.——Dr. Leo H. Bartemeier, Detroit, president of the American Psychiatric Association and chairman of the Committee on Mental Health of the American Medical Association, has been appointed a member of the National Manpower Council, a private organization established at Columbia University, New York, by President Eisenhower in 1951.——Dr. Warren A. Smith, Berrien Springs, who has served his community for 50 years as a physician and has frequently been its health officer, was recently honored at an open house at the Lions' clubhouse, sponsored by numerous fraternal and civic organizations.——Dr. Harold F. Closz, Muskegon, has been awarded an honorary degree of doctor of science by Central College, Pella, Iowa, from which he was graduated 50 years ago. Dr. Closz, who has been surgical consultant at Mercy Hospital from 1925, was also affiliated with Hackley Hospital from that date, serving as chief of surgery or chief of staff from 1932 to 1950.——Dr. William T. Hyslop, who has been a member of the Traverse City State Hospital staff since 1938 and in charge of the outpatient department and mental hygiene clinics since 1940, has been appointed director of the adult mental health clinic of Saginaw General Hospital. The new clinic, which will be jointly supported by state and local funds and will serve mentally disturbed adults from Saginaw, Bay, Midland, and Tuscola counties, will be housed in the Davis House Nursing Home.

NEW JERSEY

Society News.—The Radiological Society of New Jersey has elected the following officers for 1953-1954: Drs. Vincent M. Whelan, Red Bank, president; Nicholas G. Demy, Plainfield, vice-president; Salomon Silvera, Jersey City, secretary; and Carye-Belle Henle, Newark, treasurer.——At its annual meeting, the New Jersey Dermatological Society elected Drs. Frederick C. Licks, South Orange, president; Emanuel M. Satulsky, Elizabeth, vice-president; Seymour L. Hanfling, East Orange, secretary; and Harry C. Goldberg, Plainfield, treasurer.

Belgian Awards for Tryparsamide Research.—The Belgian government recently presented the Cross of the Belgian Royal Order of the Lion and a $10,000 award to Dr. Louise Pearce, Belle Mead, for her work on the use of tryparsamide in the control of sleeping sickness. Dr. Pearce studied the effects of the drug on sleeping sickness in the Belgian Congo where it is now widely used. Later, with three collaborators, she continued the research at the Rockefeller Institute in New York. Two of her colleagues, Walter A. Jacobs, Ph.D., New Rochelle, and Michael Heidelberger, Ph.D., of Columbia University College of Physicians and Surgeons, New York, were awarded the decoration of Officer of the Order of Leopold II in ceremonies at the St. Regis Hotel, New York, and were given $2,000 each. An additional $4,000 was paid to the estate of the third collaborator, the late Dr. W. H. Brown of Princeton University.

NEW MEXICO

State Medical Election.—At the annual meeting in Albuquerque the New Mexico Medical Society elected Dr. Albert S. Lathrop of Santa Fe, president, Dr. John F. Conway, Clovis, president-elect, Dr. Stuart W. Adler, Albuquerque, vice-president, and Dr. Theodore E. Kircher Jr., Albuquerque, secretary-treasurer.

NEW YORK

Fellowship in Tuberculosis Research.—The New York Tuberculosis and Health Association announces that the James Alexander Miller fellowship for research in tuberculosis will be available from July 1, 1954, to June 30, 1955. This fellowship is designed to support a qualified medical investigator who will devote full time to a research project on tuberculosis. Assurance must be provided that the applicant will be acceptable in the laboratory or clinic of his choice and that the facilities necessary for the pursuit of the work will be available. The annual stipend will be $5,000. Awards will be announced Dec. 1. Application forms, which should be submitted in duplicate by Oct. 1, may be obtained from the New York Tuberculosis and Health Association, 386 Fourth Ave., New York 16.

Personal.—Dr. Herman E. Hilleboe, Albany, state health commissioner, has announced the provisional appointment of Dr. James J. Quinlivan, assistant director of the division of local health services, as director of the department's office of public health education. Dr. Quinlivan, who joined the state health department as an epidemiologist-in-training in 1937 after a year's private practice in Buffalo, became an assistant district state health officer in 1938, a district state health officer in 1942, and assistant director of the division of local health services in 1948.——Dr. Donald G. Dickson, Troy, has been appointed second deputy commissioner of health in the Rensselaer County health department.——Dr. Raymond G. Wearne, director of Wassaic State School for the past 16 years, has retired after 40 years of state service. Dr. Wearne has been affiliated with Binghamton State Hospital, Central Islip, Willard, Brooklyn, and Manhattan state hospitals.——Dr. Andrew C. Fleck, deputy commissioner of health in the Rensselaer County Health Department since May 29, 1950, was graduated recently from Albany Law School with a bachelor of law degree. In addition to this and his medical degree from Albany Medical College, Dr. Fleck holds a degree of master of public health, Johns Hopkins University School of Hygiene and Public Health, Baltimore.

New York City

Clinical Professors Appointed.—At the State University of New York College of Medicine, New York City, Dr. Charles W. Mueller has been appointed clinical professor of obstetrics and gynecology and Dr. Clifford F. Storey, clinical professor of surgery.

Courses in Accident Prevention.—The Center for Safety Education, New York University, announces that the fall term evening program in industrial and traffic accident prevention will begin Sept. 21. Courses offered in the fall term are:

Accident Prevention—Its Background, Objectives, and Relationships.
Philosophy and Basic Principles of Accident Prevention.
Industrial Hazards—Mechanical and Personal Control Methods.
Fire Prevention and Protection Inspection.
Organization of Fleet Safety Programs.
Vision in Industrial Safety and Motor Vehicle Operations.
Effective Speaking in Accident Prevention.
Principles of Safety Inspection.

The following special courses are also offered:

Marine Accident Prevention.
Hotel Accident Prevention.
Accident Prevention for Small Firms.
Hospital Accident Prevention.

Information may be secured from the Center for Safety Education, New York University, Washington Square, New York 3.

NORTH DAKOTA

State Medical Election.—At the annual meeting the North Dakota State Medical Association installed Dr. Joseph Sorkness of Jamestown as president and appointed Dr. Philip H. Woutat, Grand Forks, president-elect; Drs. David J. Halliday, Kenmare, and Reuben H. Waldschmidt, Bismarck, vice-presidents; Dr. Edwin H. Boerth, Bismarck, secretary; and Dr. Ernest J. Larson, Jamestown, treasurer.

OHIO

County Secretary Honored.—Dr. George A. Woodhouse, Pleasant Hill, who has served for 25 years as secretary of the Miami County Medical Association, was recently honored at the annual dinner of the association. A set of luggage was presented to Dr. and Mrs. Woodhouse on behalf of the county group. Dr. Woodhouse, who has practiced in Pleasant Hill for 28 years, has served as both president and secretary of the Second Councillor District Medical Society, has been an A. M. A. delegate from Ohio since 1942, and is active in committee work for both the state and the national associations. He is a staff member of the Memorial Hospital in Piqua and an associate staff member of Stouder Memorial Hospital, Troy. Dr. Woodhouse has served on the Board of Education in Pleasant Hill and on the Board of Public Affairs for 10 years, 8 years as its president. Dr. Dale A. Hudson of Piqua will succeed Dr. Woodhouse as secretary of the county association.

Radiological Health Training Program.—Short, tuition-free courses in radiological health will be presented by the Public Health Service at the Environmental Health Center, Cincinnati, as follows: basic courses, stressing basic radiation physics and survey techniques, Oct. 5-16, Jan. 11-22, 1954, and May 3-14, 1954; intermediate course, emphasizing laboratory assay of radioelements and x-ray survey techniques, Oct. 19-30, Jan. 25 through Feb. 5, 1954, and May 17-28, 1954; and advanced course, for professional personnel concerned in particular with occupational health problems, Feb. 8-19, 1954. These courses are designed to provide personnel working in health departments and other organizations with knowledge of the health hazards associated with radiation. Candidates should have a degree in medicine, engineering, or science (physical or biological). Information may be obtained from the Chief, Radiological Health Training Section, Public Health Service, Environmental Health Center, Cincinnati.

TENNESSEE

University News.—Dr. Daniel A. Brody, part-time instructor in medicine at the University of Tennessee College of Medicine, Memphis, has joined the division of medicine on a full-time basis.——Dr. Frank L. Roberts, assistant dean of the University of Tennessee College of Medicine, Memphis, since 1949, has been promoted to the position of associate dean. Dr. Roberts, who joined the staff of the college of medicine in 1936 as professor and chief of the division of preventive medicine, was public health officer of Gibson County for many years before he moved to Memphis. He is president of the Tennessee Public Health Association.

TEXAS

State Medical Election.—At its centennial session in Houston the Texas Medical Association elected Dr. George Turner, El Paso, president; Dr. Francis J. L. Blasingame, Wharton, president-elect; Dr. Andrew S. Tomb, Victoria, vice-president; Dr. John M. Travis, Jacksonville, secretary; and Dr. Thomas H. Thomason, Fort Worth, treasurer.

Personal.—Dr. Hatch W. Cummings Jr., Houston, was recently elected president of the Texas Academy of Internal Medicine.——Dr. Theodore R. Hannon, a former president of the Harris County Medical Society, was recently named president of St. Joseph's Infirmary medical staff, Houston.——Dr. Alvis E. Greer, Houston, president-elect of the American College of Physicians, has announced his retirement as editor of the *Medical Record and Annals,* after eight years in that position. Dr. Greer has served as president of the Harris County Medical Society and as chairman of the A. M. A. Section on Diseases of the Chest, and is professor of clinical medicine, Baylor University College of Medicine, Houston.——Dr. C. Frank Brown, Dallas, has been appointed medical director of the Southwestern Life Insurance Company of Dallas.

Society News.—At a recent meeting in Houston the Texas Diabetes Association elected Dr. Raymond L. Gregory, Galveston, president; Drs. George M. Jones, Dallas, and Laurence B. Reppert, San Antonio, vice-presidents; and Dr. Edmond K.

Doak, Houston, secretary-treasurer.——At the annual meeting, the Texas Neuropsychiatric Association named Dr. James R. Blair, San Antonio, president; Drs. Stephen Weisz, Dallas, and Edgar S. Ezell, Fort Worth, vice-presidents; and Dr. John L. Otto, Galveston, secretary-treasurer.——The Texas Orthopedic Association, during its annual meeting in Houston, elected Dr. Edward T. Smith, Houston, president, and Dr. John J. Hinchey, San Antonio, vice-president. Dr. Margaret Watkins, Dallas, was re-elected to serve as secretary-treasurer.——The Texas Dermatological Association has selected Dr. Maurice C. Barnes, Waco, president, and Dr. C. Duncan Stewart, Corpus Christi, vice-president. Dr. Thomas L. Shields, Fort Worth, was re-elected secretary.——The Texas Society of Gastroenterologists and Proctologists has named Dr. Cecil O. Patterson, Dallas, president; Drs. J. Wade Harris, Houston, and Edward J. Lefeber, Galveston, vice-presidents; and Dr. William T. Arnold, Houston, secretary-treasurer.——At the annual meeting in Houston, the Texas Railway and Traumatic Surgical Association elected Dr. William E. Crump, Wichita Falls, president; Drs. Raleigh R. White, Temple, and Albert O. Singleton Jr., Galveston, vice-presidents; and Dr. Walford D. Marrs, Fort Worth, secretary-treasurer.——Dr. James B. Robinett Jr., Houston, took office as president of the Texas Society of Anesthesiologists at its meeting in Houston. Other officers named at the meeting were Drs. Frank O. Barrett, El Paso, president-elect; Joe B. Wood, Dallas, vice-president; and Charles R. Allen, Galveston, secretary-treasurer.——Dr. Charles L. McGehee has been named president of the International Medical Assembly of Southwest Texas; Dr. John J. Hinchey, president-elect; Drs. Marvin A. Childers and Adolfo Urrutia, vice-presidents; and Dr. John M. Smith, secretary-treasurer. All the officers reside in San Antonio.——During its meeting in Houston, the Texas Heart Association installed Dr. Joseph F. McVeigh, Fort Worth, as president. Dr. George R. Herrmann, Galveston, was chosen president-elect; Dr. Daniel D. Warren, Waco, vice-president; and Mr. R. L. Thomas, Dallas, secretary-treasurer. Executive director and executive secretary are, respectively, Mr. Edgar M. Brown and Miss Roberta Miller, both of Dallas.

WEST VIRGINIA

State Medical Election.—At the annual meeting at White Sulphur Springs, the West Virginia Medical Association elected Dr. Russell Kessel, Charleston, president, to take office Jan. 1, 1954, and Drs. George F. Evans, Clarksburg, and James L. Patterson, Logan, first and second vice-presidents, respectively. Dr. T. Maxfield Barber, Charleston, was renamed treasurer for his 27th consecutive term. The 1954 convention will be held at the Greenbrier in White Sulphur Springs, Aug. 19-21.

WISCONSIN

Dr. Bear Honored.—At the annual dinner for medical men given by the sisters of St. Clare Hospital in Monroe, Dr. Wilson G. Bear was commended for his 50 years of service to the Monroe community. One of the founders of the Monroe Clinic, Dr. Bear was also active in developing the Loofbourow Hospital (now the Evangelical Deaconess Hospital) and formerly served as chief of staff of St. Clare Hospital.

Orthopedic Clinics.—Orthopedic field clinics have been scheduled as follows by the Bureau for Handicapped Children, State Department of Public Instruction, for persons under 21: Ashland, Aug. 13-14; Wausau, Aug. 26-27; Manitowoc, Sept. 2-3; Marinette, Sept. 9; Kenosha, Sept. 16-17; Green Bay, Sept. 24-25; Superior, Sept. 30-Oct. 1; Racine, Oct. 8-9; La Crosse, Oct. 13-16; Sheboygan, Oct. 20-30; Chippewa Falls, Nov. 3-4; Rhinelander, Nov. 11-12; Eau Claire, Nov. 19-20; Appleton, Nov. 23-24; and Fond du Lac, Dec. 2-3. Parents and physicians are invited to attend the clinic with the child. If the public health nurse believes that the child referred to the clinic for orthopedic reasons is also in need of other services, the bureau asks that it be notified of this fact. Referral forms, obtainable from the Bureau for Handicapped Children, Room 146 North, State Capitol, Madison 2, should be requested in advance of the clinic date.

GENERAL

Grants for Travel to Science Congress.—The National Science Foundation will receive applications for grants to assist in payment of travel expenses to the Pacific Science Congress, Quezon City, Philippines, Nov. 16-28. Application forms, which may be obtained from the National Science Foundation, Washington 25, D. C., should be filed before Sept. 1.

Congress of Ophthalmology Invites Papers.—The International Congress of Ophthalmology, which will be held in New York, Sept. 12-17, 1954, has selected as the chief topics for discussion primary glaucoma and etiology of uveitis. A number of voluntary papers by authors on subjects of their own choosing will also be heard. Original papers should be sent before Jan. 1, 1954, to the secretary-general, Dr. William L. Benedict, 100 First Ave. Bldg., Rochester, Minn.

Crippled Children's Magazine.—With the June issue, the *Crippled Child* magazine adopted a new format and a change in its 30-year-old editorial policy. Formerly directed at professional workers, it will now be directed more toward the problems confronting parents and others interested in guiding the lives of crippled children. Technical material will henceforth be issued in special pamphlets. Named as consulting editors of the magazine, which is published by the National Society for Crippled Children and Adults, are Dr. Noah D. Fabricant, Chicago, and Earl S. Miers, member of the executive committee of the society.

Physicians Needed in Canal Zone.—The Health Bureau, Canal Zone, is urgently in need of physicians. Vacancies occur from time to time in practically all specialties, but the present shortage is most acute in the field of obstetrics and gynecology; there are vacancies also for general practitioners. Starting salaries range from $7,425 (Civil Service rating GS-11) to $10,450 (Civil Service rating GS-13), according to training, experience, and type of position. Free transportation to the Canal Zone is provided for the appointee, legal dependents, and household goods. Family housing is available. There are good hospitals, schools, and churches under standard American living conditions. A two month vacation with pay (which includes time lost for illness) is allowed, and reduced rates are granted on Panama Line vessels between the Canal Zone and New York. Positions come under Civil Service. Applicants should write to Health Director or Personnel Director, Balboa Heights, Canal Zone.

Society News.—At its annual meeting in Atlantic City, N. J., the Society for Pediatric Research elected Drs. Harold E. Harrison, Baltimore, president; Russell J. Blattner, Houston, Texas, vice-president; Sydney S. Gellis, Boston, secretary-treasurer; and Charles U. Lowe, Buffalo, and C. Henry Kempe, San Francisco, members of the council.——The American Pediatric Society has elected Drs. Rustin McIntosh, New York City, president; Wilburt C. Davison, Durham, N. C., vice-president; Aims C. McGuiness, Philadelphia, secretary-treasurer; Stewart H. Clifford, Brookline, Mass., recorder-editor; and John A. Anderson, Salt Lake City, member of the council (7 years).——At the annual meeting at Jasper National Park, Alberta, Canada, the Pacific Northwest Obstetrical and Gynecological Association elected Drs. William M. Wilson, Portland, Ore., president; John H. Harrison, Vancouver, Wash., president-elect; Richard D. Reekie, Spokane, Wash., vice-president; Earl L. Hall, Great Falls, Mont., secretary; and Verne J. Reynolds, Boise, Idaho, and Albert Trites, Vancouver, B. C., executive members.

Blakeslee Award Contest.—The American Heart Association announces that entries are now being received for the second annual Howard W. Blakeslee award of $1,000 for outstanding scientific reporting in the field of heart and blood vessel diseases. The award will be presented to the person whose creative efforts during 1953 in any medium of mass communication—including newspapers, magazines, radio, television, films, or books—are judged to have contributed most to public understanding of heart and circulatory diseases. Entries will be judged on the basis of (1) accuracy and significance; (2) the skill and originality with which advances in research, and in the treatment, care, and prevention of cardiovascular disease are translated into educational material of interest and value to the general public; and (3) the ability of the entrant to project a positive and hopeful viewpoint toward problems of the heart and circulation. Material published or produced during the 1953 calendar year is eligible for consideration. Entries must be postmarked not later than Jan. 15, 1954. The winner will be announced at the annual meeting of the American Heart Association, in April, 1954, in Chicago. Entry blanks and additional information may be obtained from the Chairman, Managing Committee, Howard W. Blakeslee Award, American Heart Association, 44 E. 23rd St., New York 10.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories, and possessions in the weeks ended as indicated:

LATIN AMERICA

Surgeons to Meet in Brazil.—The second congress of the Brazilian section and the first Panamerican congress of the International College of Surgeons will be held in Curitiba, State of Parana, Oct. 5-9. Official themes are "Death During Anesthesia," "Thoracotomy: Indications and Contraindications," and "Surgery of the Biliary Ducts." Correspondence should be addressed to the Brazilian Section of the International College of Surgeons, Rua Cesario Motta, 112—Predio Conde de Lara, São Paulo, Brazil, or International Secretariat, International College of Surgeons, 1516-24 Lake Shore Drive, Chicago 10.

FOREIGN

Ford Foundation Grant to Israel.—The Ford Foundation has made a grant of $410,000 to Israel for the solution of the basic problems of food production, health in the semitropical climate, and the adjustment of immigrants. Medical research problems assigned to the Hebrew University-Hadassah Medical School, Jerusalem, include cures for diarrhea, gastroenteritis, and fungus diseases of the skin and nails as well as means of combating trachoma and schistosomiasis.

World Federation for Mental Health.—The annual meeting of the World Federation for Mental Health will convene at the University of Vienna, Austria, Aug. 16-22. The theme of the meeting is "Social Provision for Mental Health." The seventh annual meeting is to be held in Toronto, Canada, at the same time as the fifth International Congress on Mental Health, Aug. 14-21, 1954. The theme of these meetings will be "Mental Health in Public Affairs." Information may be had from the Secretary, National Association for Mental Health, 39 Queen St., London, W.1, England.

Funds for Expansion of Health Center.—With a five year grant of 35 million francs and $28,000 (approximately $133,000) to the Association d'Hygiène de L'Aisne, the Rockefeller Foundation has renewed its support of the Soissons Public Health Center at Soissons, France. The French Ministry of Public Health and Population, with the aid of WHO and UNICEF and an earlier foundation grant, has established a center at Soissons, about 60 miles east of Paris, to study public health and medical care problems in a limited area and to work for improvements that could be applied to the country as a whole. Plans for expansion of the Soissons program are under way.

Essay Contest.—The Academy of Medicine of Turin announces a competition for the first Saint Vincent Prize for Medical Sciences (7,500,000 lira, approximately $1,200), established to promote scientific research in the medical field. The prize is offered for an essay or a group of essays, printed, dealing with a single subject related to a medical branch and representing noteworthy progress in the knowledge of the investigated matter. Essays must have been published (in Italian, Latin, French, English, Spanish, Portuguese, German, or Russian) after 1950 and must reach the Academy of Medicine in Turin, Via Po, 18, not later than Dec. 31. Five copies, two of which shall remain the property of the academy, with a summary in Italian or French concerning the substance as well as the original and concluding parts of the subject matter, should be sent by registered mail. The winner will be announced at Saint Vincent, Valley of Aosta, in June, 1954, at a meeting sponsored by the academy.

CORRECTIONS

Arterenol in the Treatment of Shock.—In the article by this title in THE JOURNAL, July 25, 1953, page 1200, the first sentence in the last paragraph of the left hand column should read as follows: "Arterenol was given continuously in this series of patients for ½ to 36 hours, without ill effects becoming manifest."

Transfusion of Platelets.—In the editorial on this subject in THE JOURNAL, Aug. 8, 1953, page 1434, the temperature given in the next to last paragraph of the right-hand column should be 5 C instead of 51 C.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1953 Clinical Session, St. Louis, Dec. 1-4.

1954 Annual Session, San Francisco, June 21-25.

1954 Clinical Session, Miami, Florida, Nov. 30-Dec. 3.

1955 Annual Session, Atlantic City, N. J., June 6-10.

1955 Clinical Session, Boston, Nov. 29-Dec. 2.

National Conference on Physicians and Schools, Moraine-on-the-Lake Hotel, Highland Park, Ill., Sept. 30-Oct. 2. Dr. W. W. Bauer, 535 N. Dearborn St., Chicago 10, Director.

Public Relations Institute, Drake Hotel, Chicago, Sept. 2-3. Mr. Leo E. Brown, 535 North Dearborn St., Chicago 10, Director.

American Academy of Pediatrics, Municipal Auditorium, Miami, Fla., Oct. 6-9. Dr. E. H. Christopherson, 610 Church St., Evanston, Ill., Secretary.

American Association of Medical Clinics, Congress Hotel, Chicago, Oct. 9-11. Dr. Edwin P. Jordan, P. O. Box 114, Charlottesville, Va., Executive Director.

American Association of Medical Record Librarians, Palace Hotel, San Francisco, Oct. 5-9. Miss Doris Gleason, 510 N. Dearborn St., Chicago 10, Executive Secretary.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, The Homestead, Hot Springs, Va., Sept. 10-12. Dr. William F. Mengert, 2211 Oak Lawn Ave., Dallas, Texas, Secretary.

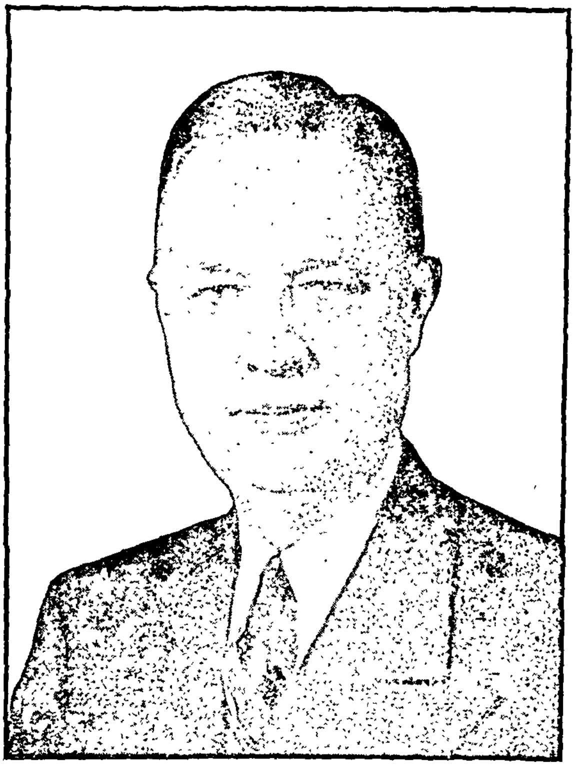
Board of Thoracic Surgery: *Written.* Various centers throughout the country, September 11. Final date for filing application was July 1. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2.

DEATHS

Henderson, Elmer Lee ⊕ Louisville, Ky., President of the American Medical Association, 1950-1951, and from June, 1947, to June, 1949, chairman of the Board of Trustees, died July 30, aged 68, of carcinoma of the prostate. Dr. Henderson was born in Garnettsville, Ky., March 23, 1885. In 1909 he received the degree of doctor of medicine from the University of Louisville Medical Department, where for many years he was a member of the faculty and where he served as a member of the board of overseers. Since 1911 Dr. Henderson had practiced general surgery in Louisville. In World War I he was a major in the U. S. Army Medical Corps, serving nine months overseas. He was later commissioned a lieutenant colonel in the Medical Reserve Corps. In World War II he was chairman of the Fifth Service Command Committee, Procurement and Assignment Service for Physicians, Dentists, and Veterinarians. Since 1943 he had been a surgical consultant to the Air Surgeon's Office, U. S. Army. In 1948 he was a member of a mission to Japan to survey and make recommendations on social security, medical education, and medical service. In his long service in organized medicine, Dr. Henderson was a member of the House of Delegates of the American Medical Association from 1937 to 1939, and was elected a member of the Board of Trustees in 1939. He was elected vice-chairman of the Board in December, 1945. He served as chairman of the Board's executive committee for two years, and then was elected chairman of the Board. He gave up that office in 1949 when, by unanimous vote of the House of Delegates, he was made President-Elect. He served as president of the World Medical Association, chairman of its United States committee, and at the time of his death was a member of the council. Dr. Henderson was a past president of the Kentucky State Medical Association, of the Jefferson County Medical Society, of the Southeastern Surgical Congress, of the Southern Medical Association, and of the Alumni Association of the University of Louisville. He was one of the founders of the American Board of Surgery, a fellow of the Società Piemontese di Chirurgia, and the Japanese Medical Association, honorary member of the International College of Surgeons, and a member of the board of trustees of the National Society for Crippled Children and Adults. He was a member of the board of governors and consultant in surgery at the Kosair Crippled Children Hospital, consultant on the staff at SS Mary and Elizabeth Hospital, and on the surgical staff of Kentucky Baptist Hospital and St. Joseph Infirmary.



Elmer Lee Henderson, M.D., 1885-1953

Mann, William Leake ⊕ Rear Admiral, U. S. Navy, retired, Arlington, Va.; born in Georgetown, Texas, July 26, 1884; Harvard Medical School, Boston, 1908; graduate of Naval Medical School, Naval War College, the Army Field Service School at Carlisle Barracks, Pa., and the Navy's School of Aviation Medicine; in October, 1908, was appointed assistant surgeon with the rank of lieutenant (jg) in the medical corps of the Navy; advanced through the various ranks to that of rear admiral which he attained in July, 1943; served at Navy medical department facilities throughout the United States, in China, in the Philippine Islands, and in Haiti; his tours of sea duty included assignments aboard the USS Tennessee, the USS Hannibal, the USS Cincinnati, and the aircraft carrier, the USS Saratoga; a veteran of World Wars I and II, was credited with the development of medical companies and was instrumental in getting them written into the table of organization of the marine corps; from 1940 to 1942 was medical officer in command of the Naval Hospital, Corpus Christi, Texas, and following this assignment became the first commanding officer of the Naval Medical Research Institute, Bethesda, Md.; following his advancement to the rank of rear admiral in 1943, became district medical officer of the 13th naval district with headquarters at Seattle, Wash.; was placed on the retired list of the Navy, Nov. 1, 1945, after more than 37 years of continuous active naval service; fellow of the American College of Surgeons; in 1943 president of the Association of Military Surgeons of the United States; delegate to the International Congress of Military Medicine, Bucharest, Rumania, 1937; was awarded a special letter of commendation by the Navy Department for service in World War I, World War I medal, Medal Militaire (Haiti), and Haitian Campaign medal; died June 12, aged 69, of adenocarcinoma of the stomach.

Rudolph, Myron Parkhill ⊕ Col. U. S. Army, retired, Raleigh, N. C.; born in Punxsutawney, Pa., Jan. 28, 1889; Hahnemann Medical College and Hospital of Philadelphia, 1915; received the degree of doctor of public health from Johns Hopkins University, Baltimore, 1937; commissioned a first lieutenant in the medical corps of the Army in 1917; subsequently served in all commissioned ranks of the regular Army and was promoted to the rank of colonel in 1942; during World War I served with the Sixth Infantry and was decorated for gallantry in action; during World War II served in North Africa and as surgeon of the U. S. Seventh Army in Europe; following the war, served as chief of preventive medicine in Germany and as surgeon for the Third Army, Fort McPherson, Ga., until his retirement in January, 1949; during his military career, was awarded the Silver Star, the Distinguished Service Medal, the Legion of Merit, the Bronze Star Medal, and the Purple Heart; received the French Croix de Guerre from the French government; awarded the United States of America Typhus Commission Medal; specialist certified by the American Board of Public Health; member of the American Public Health Association; chief of the maternal child health clinic and crippled children's section of the North Carolina State Board of Health; died June 30, aged 64, of coronary sclerosis and myocardial infarction.

⊕ Indicates Member of the American Medical Association.

Kolb, Edwin Paul ⊕ Patchogue, N. Y.; born in Frostburg, Md., July 8, 1883; University of Maryland School of Medicine, Baltimore, 1912; from 1926 to 1951 secretary of the Suffolk County Medical Society, of which he was president; past president of the Associated Physicians of Long Island and the South Side Clinical Society; specialist certified by the American Board of Internal Medicine; member of the American College of Chest Physicians; fellow of the American College of Physicians; served during World Wars I and II; consultant, Central Island (N. Y.) State Hospital, Kings Park State Hospital in Kings Park, Pilgrim State Hospital in Brentwood, Southampton (N. Y.) Hospital, South Side Hospital in Bay Shore, and John T. Mather Memorial Hospital in Port Jefferson; retired April 30, 1949, after 33 years as superintendent of the Suffolk Sanatorium in Holtsville; director of the Peoples National Bank; died June 14, aged 69, of coronary occlusion.

J.) Medical Society; formerly practiced in Paterson, N. J., where he was affiliated with Paterson General Hospital; died in Waukesha Memorial Hospital recently, aged 91, of cerebral hemorrhage and hypertension.

Fort, Mannie Almanza ⊕ Bainbridge, Ga.; Tulane University of Louisiana School of Medicine, New Orleans, 1903; died May 9, aged 80, of ileus.

Goodrich, Benjamin Elmer ⊕ Detroit; State University of Iowa College of Medicine, Iowa City, 1926; specialist certified by the American Board of Internal Medicine; member of the Central Society for Clinical Research, American College of Chest Physicians (as well as past president of the Michigan Chapter), and the American Trudeau Society; fellow of the American College of Physicians; served during World War I and World War II; affiliated with Henry Ford Hospital; died in Pleasant Ridge, Mich., June 15, aged 53, of coronary occlusion.

Guenther, Edward George, Burlington, Iowa; Hospital College of Medicine, Louisville, Ky., 1898; died April 14, aged 77, of acute coronary thrombosis and hypertensive cardiovascular disease.

Hansen, Elmer Harry, Long Beach, Calif.; Tulane University of Louisiana School of Medicine, New Orleans, 1918; died in Veterans Administration Hospital June 16, aged 63, of carcinoma.

Hughes, Michael Edward ⊕ Lieut. Col., U. S. Army, retired, Los Angeles; Bellevue Hospital Medical College, New York, 1893; served in the Spanish-American War and World War I; died June 1, aged 83.

Jones, Daniel Dailey ⊕ Berne, Ind.; Northwestern University School of Medicine, Chicago, 1909; served during World War I; formerly health officer; died June 11, aged 82, of cerebral thrombosis and arteriosclerosis.

Jessup, Horace Sihler ⊕ Sequim, Wash.; McGill University Faculty of Medicine, Montreal, Canada, 1923; served during World War II; died April 3, aged 52, of multiple sclerosis.

Keene, Walter Bullock, Philadelphia; Jefferson Medical College of Philadelphia, 1891; died June 11, aged 85.

Kline, Philip, Tulsa, Okla.; University of Nebraska College of Medicine, Omaha, 1919; served during World War I; at one time president of the alumni association of the University of Nebraska; for a long time official physician for Northeast Oklahoma Golden Gloves tournament and all dual boxing matches; died June 16, aged 62, of coronary occlusion.

Knepp, James Warren ⊕ Manchester, N. H.; University College of Medicine, Richmond, 1905; a captain in the medical corps of the Army during the Mexican border campaign in 1916; served during World Wars I and II; affiliated with the Veterans Administration; died in Newtown, Conn., June 11, aged 72.

Koop, Severin Herman ⊕ Richmond, Minn.; University of Minnesota Medical School, Minneapolis, 1927; member of the American Academy of General Practice; superintendent of the Richmond Hospital; died in Minneapolis recently, aged 54, of coronary occlusion.

Kratzer, Eugene Ferdinand ⊕ Kokomo, Ind.; Medical College of Indiana, Indianapolis, 1903; also a graduate in pharmacy; died in Robert Long Hospital, Indianapolis, June 1, aged 76, of bronchogenic carcinoma.

Law, Charles Royce ⊕ Coolidge, Ariz.; Rush Medical College, Chicago, 1938; served during World War II; died June 5, aged 43, of a heart attack.

McCarthy, Edward, New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1900; served during World War I; died June 10, aged 75, of myocarditis.

McKinnon, Daniel Angus ⊕ Marianna, Fla.; Medical Department of Tulane University of Louisiana, New Orleans, 1905; died in Albuquerque, N. Mex., March 17, aged 75, of diverticulitis.

Manning, Ernest Tibbetts ⊕ Omaha; Rush Medical College, Chicago, 1904; specialist certified by the American Board of Pathology; member of the College of American Pathologists and the American Society of Clinical Pathologists; at one time on the faculty of the University of Nebraska College of Medicine; served as vice-president and later as chairman of the state board of medical examiners; formerly health commissioner; died June 5, aged 75, of cerebral hemorrhage.

Martin, George Clark ⊕ Indiana, Pa.; Temple University School of Medicine, Philadelphia, 1928; fellow of the American College of Surgeons; past president of the Indiana County Medical Society; served during World Wars I and II; member and past president of staff of Indiana County Memorial Hospital; died April 25, aged 53, of cerebral thrombosis.

Martin, Henry Sleeper ⊕ Warsaw, N. Y.; Jefferson Medical College of Philadelphia, 1919; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; past president of the Eighth District Medical Society; chief of staff emeritus at the Wyoming County Community Hospital; died June 11, aged 62, of cerebral hemorrhage.

Martin, John Letton, Washington, D. C.; University and Bellevue Hospital Medical College, New York, 1899; died June 15, aged 74, of acute congestive heart failure.

Martt, Sherman Guthrie, Pomeroy, Ohio; University of Louisville (Ky.) Medical Department, 1894; died June 18, aged 83, of a heart attack.

Morgan, Isaiah C. ⊕ Nanticoke, Pa.; Jefferson Medical College of Philadelphia, 1915; served during World War I; formerly county coroner; affiliated with Nanticoke State Hospital; served as chief medical examiner of the Veterans Administration in Wilkes-Barre regional office; president of the radio station WILK; died in Nuangola, Pa., April 26, aged 60, of coronary thrombosis.

Mueller, James Alexius ⊕ Lewistown, Mont.; State University of Iowa College of Medicine, Iowa City, 1932; member of the American Academy of General Practice; county physician; on the staff of St. Joseph's Hospital; died in Fenton, Iowa, May 30, aged 52, of injuries received in an airplane crash.

Nelson, Richard Buzzard ⊕ Hammond, Ind.; Indiana University School of Medicine, Indianapolis, 1933; also a graduate in pharmacy; member of the Association of Military Surgeons of the United States; served during World War II; affiliated with St. Margaret's Hospital, where he died June 9, aged 44, of coronary thrombosis.

Nichols, Robert Columbus ⊕ Ontario, Calif.; Northwestern University Medical School, Chicago, 1911; died March 29, aged 73, of coronary artery disease.

Nissler, Christian William ⊕ Lansdowne, Pa.; Jefferson Medical College of Philadelphia, 1919; member of the American College of Chest Physicians and the American Trudeau Society; for many years on the faculty of his alma mater; formerly medical director of White Haven (Pa.) Sanatorium; died May 31, aged 64, of coronary occlusion.

Norment, Richard Baxter Jr. ⊕ Hagerstown, Md.; University of Maryland School of Medicine, Baltimore, 1914; formerly associated with the U. S. Public Health Service; died in Washington County Hospital April 6, aged 61.

Noyes, William Bradbury, New York City; Columbia University College of Physicians and Surgeons, New York, 1891; served on the staffs of the Mountainside Hospital in Montclair, N. J., and the Columbus Hospital; died in St. Luke's Hospital June 20, aged 87, of arteriosclerosis.

O'Connor, Andrew Francis ⊕ Reno, Nev.; Loyola University School of Medicine, Chicago, 1923; member of the California Medical Association; died in the Veterans Administration Center June 23, aged 62, of gastrointestinal hemorrhage, esophageal varices, and Laennec's cirrhosis.

Parker, Joseph Garrison, New York City; Columbia University College of Physicians and Surgeons, 1948; senior assistant surgeon in the U. S. Public Health Service Reserve, serving in Cincinnati when he became ill; certified by the National Board of Medical Examiners; served an internship in internal medicine at the Duke Hospital in Durham, N. C.; interned and served a fellowship in pathology and a residency in internal medicine at the Mount Sinai Hospital, where he died June 21, aged 29.

Pedigo, William Sherman ⊕ Strawn, Texas; University of Nashville (Tenn.) Medical Department, 1894; Vanderbilt University School of Medicine, Nashville, Tenn., 1894; served during World War I; past president of the Palo-Pinto-Parker Counties Medical Society; member of the Texas Association of Railway Surgeons; for many years city health officer; founder and part owner of the Strawn Hospital; surgeon for the Texas and Pacific Railway Company; died March 7, aged 82, of carcinoma of the sigmoid.

Riffle, Raymond Ernest, Indianapolis; Indiana University School of Medicine, Indianapolis, 1911; died May 24, aged 66, of coronary occlusion and diabetes mellitus.

Robberson, Marvin Early ⊕ Wynnewood, Okla.; University of Louisville (Ky.) Medical Department, 1905; formerly medical director and part owner of the Wynnewood Hospital; died June 7, aged 73, of cerebral hemorrhage.

Roby, Robert Sharman, Jackson, Miss. (licensed in Mississippi in 1907); died June 19, aged 67.

Rooney, John Francis, Boston; College of Physicians and Surgeons, Boston, 1921; for many years police surgeon; died in Dorchester, Mass., April 5, aged 71, of coronary thrombosis.

Shamanky, Harry Solomon ⊕ Columbus, Ohio; Ohio State University College of Medicine, Columbus, 1917; served during World War II; died May 16, aged 58.

White, William Henry Clay ⊕ Elizabeth City, N. C.; University of Virginia Department of Medicine, Charlottesville, 1922; served as county coroner; died in the Albemarle Hospital May 31, aged 55, of a cerebral vascular accident and hypertension.

Wunderlich, Edwin B. ⊕ Chicago; Dearborn Medical College, Chicago, 1906; died in the Lutheran Deaconess Hospital July 3, aged 76, of arteriosclerotic heart disease.

FOREIGN LETTERS

LONDON

Preschool Child Mortality.—A review of one of the more neglected aspects of pediatrics, mortality in children aged 1 to 5 years, has recently been published from the Child Welfare Department, Edinburgh (*Edinburgh M. J.* 60:212, 1953). It is based on a study of child deaths in Edinburgh from 1901 to 1951. In 1901 the total number of deaths in this age group was 777; in 1951 it was 45, in spite of the fact that during this half century there was an increase in the population aged 1 to 5 years. The main causes of death in 1901 were as follows (the corresponding figure for 1951 is given in parentheses): measles 111 (0), whooping cough 175 (2), tuberculosis 123 (5), and bronchitis and pneumonia 130 (5). In 1951, in this age group, there were no deaths from measles, scarlet fever, or diphtheria, and only one from "diarrhoeal diseases." In view of the reputation that Edinburgh had in the earlier years of the century for the high incidence of bovine infection (in 1904, for instance, there were 2,974 cows kept by dairymen within the city, and 39 of them were removed by the city veterinary officer because of infection with tuberculosis), it is interesting to note that "the problems of prevention and control of tuberculosis is now mainly, if not entirely, that of the human type infection." The comments of the authors of this report on the present position of BCG vaccination in this country are worthy of note: "The introduction of B.C.G. vaccination in 1950 was approved nationally, but official restrictions were imposed on its general application and it can only be used for special groups of the population. Unless and until it can be made available as a routine prophylactic measure in the early days of life and steps taken to maintain the immunity thus produced, little can be expected from the restricted use of the vaccine."

The only cause of death that has not shown a satisfactory decrease is death from accidents: in 1901 there were 22 such deaths, and in 1951 there were 13. "In 1901-09 the ratio of fatal accidents occurring at home to those occurring without the home was 9:5, while in 1950-51 the corresponding ratio was 3:8. Deaths from accidental and violent causes during the first decade of the century accounted for 2.8 per cent. of the total deaths among 1-5 year olds, and during the period 1942-51 such deaths represented 14.8 per cent. of the total group deaths. Thus, accidental and violent deaths among preschool children have assumed major importance and the prevention of such deaths must be regarded as one of the primary objects of modern social medicine."

Accidents in the Home.—The latest figures on accidental deaths available for England and Wales are contained in the recently published annual report by the chief medical officer of health of the Ministry of Health. "On the State of the Public Health," concerning the period April 1, 1950, to Dec. 31, 1951, shows that in 1951 the number of deaths from motor vehicle accidents was 4,510 and from all other accidents 10,464. The corresponding figures for 1950 were 4,230 and 9,851. Domestic accidents were responsible for over 5,000 fatalities, about 20% of which occurred in children under 5 years of age and about 60% in elderly persons over 65. "It is still the case that more children under 15 die from accidental deaths in their homes than are killed on the roads; it is significant that between the ages of one and five a fatal home accident is one of the largest causes of death."

Diphtheria Immunization.—A recent circular issued by the Ministry of Health summarizes the present position with regard to diphtheria immunization in England and Wales. Notifications of diphtheria have fallen from 23,199 in 1944 to 274 in 1952 (nine months only), while the deaths have decreased from 934 in 1944 to 31 in 1952. The Minister of Health "greatly appreciates all that local authorities have done to achieve this remarkable progress," but "notes that the rate of decline in the number of deaths from diphtheria has not been so great in 1952 as in previous years." The number of children immunized under local authority arrangements (including those immunized by family physicians for whom records were received by the local authority) from the beginning of 1940 to June 30, 1952, was 10,025,032. During the first half of 1952, 287,678 children were immunized, of whom 104,293 were under 1 year of age. This last figure represents only 31% of the estimated number of children reaching the age of 1 year during this period, whereas the aim of the immunization campaign is not less than 75% of babies before their first birthday. The diphtheria immunization target for 1953 is 491,000 babies under 1 year of age.

National Spastics Society.—At the recent annual meeting of the National Spastics Society, which was formed about two years ago, some details were given concerning the facilities now available in Great Britain for the care and training of spastic children. It is estimated that there are more than 20,000 spastic patients in the country, more than half of whom are under the age of 16. Since the society was founded, a clinic has been opened in Croydon, a small school in Reading, a teaching and training center in Swansea, and a large special school for spastic children in Newcastle. Plans are being made to build a special center for these persons in Bristol, another large school in Birkenhead, a play center in Cheltenham, and a small clinic in Kingston. In addition, a small school has been opened by the Swindon Hospital Group, and the N. E. London Hospital Board has decided to open a spastic unit and clinic. The Middlesex County Council has appointed a welfare officer to examine the special needs of these patients. In conjunction with the British Council, the society is planning to turn Coombe Farm, Croydon, into a sheltered training workshop, where 16 to 25-year-old spastic persons will learn to earn a living.

Prescribers' Notes.—"Prescribers' Notes" is the title of a booklet produced by the Ministry and the Department of Health for Scotland, in cooperation with the general services committee of the British Medical Association, and distributed to all general practitioners taking part in the National Health Service. It was first published in February, 1952. The fifth, and latest, issue exemplifies the aims of the publication. It acknowledges receipt from a physician of a 3 lb. parcel containing his month's mail from proprietary drug firms. This consisted of 3 booklets, 8 blotters, 16 postcards (for samples), and 73 folders. Of the 122 preparations advertised, only 7 were priced. It is stated that "many doctors are not giving on their E.C.10's [i. e., the official N.H.S. prescription form] directions for use when tablets or capsules are prescribed." Confirmation of this was obtained by a random sample of prescriptions for tablets or capsules written by different physicians; this showed that 54% of them had given no directions whatever. Attention is also drawn to the fact that "in recent months there has been a steady increase in the average number of prescriptions per form E.C.10. A serious aspect of this increase has been a tendency to write prescriptions for different members of the

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

family on the same prescription form." An actual example is reproduced of a prescription form made out to a woman, which contains prescriptions for three different lots of tablets: one for phenobarbital, one for ephedrine, and one for amphetamine. The phenobarbital was for the mother and the other two for her young child, but there is no indication of this on the form. It is not suggested that these two types of inadequate prescribing are typical of the general standard, but it is rather disturbing to realize that even a small proportion of practitioners can be so careless in their handling of potentially dangerous drugs.

Factory Accidents.—The annual report of the chief inspector of factories for 1951 shows that there were 828 fatal accidents, compared with 799 in 1950. The number of nonfatal accidents fell from 192,260 to 182,616, the lowest figure recorded since 1938. In recording a rise of 250% (from 1,756 in 1939 to 6,241 in 1951) in the number of accidents connected with transport, the chief inspector calls for an enforcement of stricter discipline among drivers and users of these vehicles. Compared with 1939, there has been a drop of 37% in the number of cases of sepsis, which is largely attributed to the publicity campaign carried out by accident prevention organizations. Reference is made to the increasingly useful role that older persons are playing in industry, e. g., men between 65 and 70 working as part of a mill team in a tin plate works and a man of 67 working as a steel erector, and only 6.5% of the total accidents occurred in persons over the age of 60. The available evidence suggests that older persons are not more prone to injury but that the consequences of their accidents tend to be more serious. The position with regard to accidents to young persons was not so satisfactory, as they represented a higher proportion of all accidents than they did in 1950. In many factories management either did not appreciate certain fundamental characteristics of youth or failed to allow for curiosity, high spirits, immaturity, and lack of judgment.

There was a decrease in the total number of gas poisoning accidents, which fell from 242 (25 fatal) in 1950 to 228 (17 fatal) in 1951; carbon monoxide was responsible for 105 (9 fatal). There were 64 cases of lead poisoning, compared with 57 in 1950; none was fatal. There were 31 cases of anthrax (1 fatal), compared with 36 in 1950. There were 178 cases of epitheliomatous ulceration, only one of which was fatal, a record since 1920 when the condition was made notifiable. The number of notifications of chrome ulceration rose from 143 to 203; the rise was largely due to the increased number of cases among workers engaged in the manufacture of bichromates. Cases of industrial dermatitis voluntarily notified during the year were 3,281, a decrease of 290 over 1950.

On the subject of the introduction of color to make surroundings more cheerful and therefore encourage a bigger output of work, always a popular topic in these reports, reference is made to certain enlightened managements who made determined efforts to use color to the best effect, although the blacks, grays and whites of former years still persist in many cases. Reference is also made to the need for more frequent and systematic cleaning of windows, both inside and out, with a view to improving lighting facilities.

NORWAY

Prognostic Significance of the Size of a Malignant Tumor of the Breast.—Hitherto it has largely been taken for granted that the smaller a malignant tumor in the breast the better is the prognosis. Prof. Leiv Kreyberg, who is in charge of the Institute for General and Experimental Pathology at the Oslo University, has lately challenged the accuracy of this assumption and, in conjunction with Dr. Tor Christiansen, has undertaken a critical scrutiny of 974 cases of cancer of the breast examined in the period 1933-1942. This scrutiny, carried out in 1952, concerned patients with a minimum observation period of 10 years and in many cases a much longer observation period. Among these patients were 56 with tumors whose size at the first examination was that of a Norwegian hazel nut or smaller. In 10 of these cases the size of the tumor was that of only a pea or a bean. All these patients were followed up, and the cause of death was ascertained for those who died. The survivors underwent a clinical examination in 1952, when several of them were found to be suffering from metastases masquerading under the diagnosis of rheumatism. Indeed, there were as many as six women who, in spite of having passed the 10 year observation period in apparently good health, were found to be suffering from hidden metastases to which they ultimately succumbed. As only 17 of the 56 women had been under observation for as long as 14 years, it is probable that several of them will ultimately die of cancer, and the following conclusion is drawn: "More than half of all the patients with a carcinoma of the breast of the size of a hazel nut or less will succumb to their disease. . . ." Even among the 10 women with carcinomas no bigger than a pea or bean when first examined there were as many as 4 who died of metastases.

Professor Kreyberg and Dr. Christiansen have come to the conclusion that, though modern methods of treatment can delay the ultimate fatal issue, patients with exceptionally small tumors when first examined cannot count on any better prognosis than the average of patients in the first and second stages of the disease. This investigation, published in *Tidsskrift for den Norske Laegeforening* for June 1, 1952, is commented on in a leading article in the same number of this journal. Here it is pointed out that "the prognosis for a large tumor of the breast can be just as good as for a small tumor, the matter depending on the degree of malignancy. We celebrate our therapeutic triumphs when the degree of malignancy of a tumor is small."

Medical Supervision of Persons in Radiological Service.—In accordance with the Workers' Protection Act, steps were taken in 1947 to provide for the systematic supervision of persons exposed to x-rays or radium. This supervision consists of technical control provided by the state physical control laboratory and of medical control of exposed persons, whose blood is examined yearly. Responsibility for these measures rests with the state workers' supervision, whose senior medical officer is Dr. Arne Bruusgaard. A member of his staff, Dr. Per Sundby, has recently reported on this supervision, analyzing the results obtained from 1947 to the end of 1952 with 250 men and 1,054 women exposed for at least 15 hours a week to x-rays or radium in the course of their professional duties. In as many as 457 cases (40% of the total) the blood picture showed departures from the normal. Repeated examinations at short intervals of the blood of the same person showed that these abnormalities were comparatively stable. The abnormality rate was higher in certain hospitals with cramped and inconvenient quarters than in more modern quarters whose construction reflected modern standards. There was no evidence to show that a person's age or the number of years of exposure played any essential part in these abnormalities, which were most frequent in persons most exposed, such as "diagnosis nurses" and sanatorium staff members who spent much time in screening.

These blood examinations included hemoglobin determination and erythrocyte and leukocyte counts. The abnormalities found in the blood included leukopenia, lymphocytosis (granulocytopenia), shift to the left, combined changes, occasional morphological changes, and anemia. Sundby's findings, in many respects, confirm the observations previously made in Sweden by Dr. Nils G. Nordenson, whose work on blood changes in radiologists was published in 1946. Dr. Sundby refers also to the work on this subject published in 1950 in the *American Journal of Medical Science* by Dr. H. C. March. These Swedish and American studies do much to support Sundby's conclusion that there is still room for improvement with regard to the medical supervision of persons engaged in radiological work.

PARIS

Origin of Acute Tuberculosis in Children.—An important study was made on acute tuberculosis in children by Prof. R. Debré and Dr. H. E. Brissaud, who reported their results at the March 3 meeting of the National Academy of Medicine. Their aim was to discover the origin of the infection of 418 tuberculous children. In 45% of cases it was not possible to discover the tuberculous contact, but in 55% it was ascertained that the contact was one of the child's parents. In 80% of the cases the contact was known to be tuberculous but had not been isolated for various reasons, such as that he lived with his family while waiting for admission to a sanatorium, he had a leave of absence granted during treatment, or he had a relapse. Further inquiry revealed that no child had been correctly vaccinated and isolated. The authors stressed the necessity of isolating immediately the young patient from his family, of correct education of the public, and also of including tuberculosis among the diseases to be compulsorily reported.

Anticoagulative Action of Sympathicolytics.—At the Jan. 9 meeting of the Medical Society of the Paris Hospitals, P. Uhry and H. Kaufmann presented a paper on the influence of sympathicolytics on blood coagulation. It is known that sympathetic excitation provokes hypercoagulability and that, on the other hand, heparin is an anticoagulant. It is also known that the use of sympathicolytics and heparin therapy are two methods of treatment of angina pectoris. The authors wondered if, by injecting sympathicolytics alone, the same hypocoagulability would not be obtained as with heparin. They used the following drugs: (*a*) a piperoxan derivative (933F); (*b*) an imidaziole derivative, tolazoline hydrochloride, and another derivative; (*c*) a mixture of equal parts of three dihydrogenated ergotoxine alkaloids (Hydergine); and (*d*) pentamethonium bromide. At the same time they studied the influence on the blood of two vasodilators: acetylcholine chloride and sodium nicotinate. Hypocoagulability was determined by Howell's and Quick's prothrombin tests and the heparin tolerance test. Very small doses were used in order to avoid sudden hypotension. The authors could observe the anticoagulative effect of all sympathicolytics either 15 minutes, 1 hour, or 3 hours after intravenous injection. The action was constant in 30 of 31 cases. The anticoagulative action is particularly noticeable after injection of the piperoxan derivative (933F), which is an adrenolytic. The authors stressed that the injection should not be given by perfusion, perfused substances having their particular action on the coagulability of the blood. The studies made on the two nonsympathicolytic vasodilators yielded quite different results. The injection of sodium nicotinate produced an intensive vasodilatation, but, after brief hypocoagulability, hypercoagulability occurred. The same effects occur after intravenous injection of acetylcholine chloride, and are probably due to hypersecretion of epinephrine provoked by acetylcholine. This research is considered important from the clinical and therapeutic points of view, and it is still in progress.

New Roentgenographic Techniques.—In 1950, Van der Plaats showed that by reducing the x-ray tube focus from 1 mm. to 0.3 mm. the blurring of the image was avoided and that the use of punctiform foci produced enlarged images having very sharp outlines. F. Layani, H. Fischgold, and L. Perles thought of combining both processes for making roentgenograms of bone, the images enlarged by means of a punctiform tube, according to Van der Plaats' method, being once more enlarged by photography. The technique of this two stage enlargement is as follows: A direct enlargement of 2.5 to 3 times is obtained with a 0.3 mm. tube, standard Kodak films, and finely grained screens. Then the roentgenogram enlarged 2.5 to 3 times by photography. Thus, a total enlargement of about 6 times is obtained; according to the authors, this is a maximum, above which images become easily blurred. On Nov. 28, 1952, the authors reported the results of this procedure to the Medical Society of the Paris Hospitals. They observed that this technique is most successful with the thinner bones of the limbs, ribs, and skull. They showed some very illustrative films. The authors stressed that studies on a large scale are in progress, but that it may be stated now that osseous architecture undergoes a transformation with aging and that this transformation is radiologically observable on the living bone with this new method.

Pierre Bourgeois, R. Lacourbe, and J. Remy described at the meeting on Feb. 27 a technique of bronchography also based on Van de Plaats' work. They observed that, with this method of enlargement of the image by 2, the widening of the image is such that, in bronchograms with iodized oil (Lipiodol) the images of bronchial arborizations become dissociated and much more visible. The authors use the following technique: a focus-film distance of 80 cm., tension of 80 to 90 kv, and exposure for 0.05 to 0.08 of a second. As contrast medium they used a mixture of heavy iodized oil with very fine pure talc, 9 gm. of talc in 20 cc. of the oil. Thus the bronchial tree fills slowly, alveolar cramming is avoided, evacuation lasts for a few days, and a thin layer persists in coating bronchial walls, permitting the study of the deformation of the mucosa. This method may also be used for the study of the pulmonary parenchyma, as in miliary tuberculosis.

Study of Lipoproteins with Electrophoresis.—In France a simple and rapid method is used to measure serum lipoproteins by the precipitation curve of serum euglobulins with relation to the pH, or Sandor's reticuloendothelial index card. (Sandor of the Pasteur Institute has made extensive studies on serum euglobulins and published a series of papers in recent years on this question.) R. Raynaud, J. R. Déshougues, P. Pasquet, and S. Di Giovanni succeeded in showing that euglobulins of pH 6 contain almost all of the serum lipids and that the level of these stable euglobulins in normal persons represents exactly the total level of circulating lipoproteins. Like other methods, this method of measurement of lipoproteins is only quantitative.

R. Raynaud and his associates have applied electrophoresis on paper to the study of atherosclerosis. The paper strips on which electrophoretic migration takes place are colored by black sudan, and the others by aminoschwartz. The sudan strips show the lipid and the aminoschwartz strips the protide fraction of the serum. Thus lipidogram and protidogram curves are obtained that permit analysis of the qualitative modification of these elements. In a normal lipidoprotidogram, the following fractions are observed: first, the alpha fraction, which is slightly noticeable and negligible with regard to albumin; second, the group of gamma fractions, including the gamma rapid and gamma slow fractions; and third, the three beta fractions, beta rapid, beta slow, and beta very slow. The most important fraction is the beta rapid. The authors observed that, in normal persons to whom a meal rich in fats was given, lipidoprotidograms taken hourly showed that the abounding giant lipidoprotidic molecules, found in the blood after the meal, progressively become lighter molecules within a few hours. They studied the lipidoprotidograms of 16 patients with atherosclerosis, 11 of which had characteristic lipodograms, that is, a quite noticeable diminution of the rapid beta fraction, the appearance of a very important slow beta fraction intermediate between the normal slow beta and the beta rapid. This abnormal slow beta fraction is always strongly colored by black sudan and extends in a rapid beta fraction. The authors were unable to learn the relation between these abnormal lipidograms and the very variable levels of lipoidemia and cholesterolemia. Moreover, 5 of the 11 patients had definite blood hypercoagulability, 2 isocoagulability, and 4 hypocoagulability. Five of 16 patients with atherosclerosis had normal lipidograms, and all 5 had hypocoagulability. The authors have come to the following conclusion: Patients with atherosclerosis with blood hypercoagulability have an abnormally high level of slow beta lipidoproteins. They were able to observe, in the same subjects, the changes in lipidograms under the influence of anticoagulant treatment; in another case, accentuation of the abnormal lipidogram coincided with a relative increase of the blood hypercoagulability. The authors note that there is a certain relation between blood coagulability and the rapidity of electrophoretic migration of serum lipoproteins in patients with atherosclerosis, but the relation is not absolute. Additional work on this subject is in progress.

Diagnosis of Hemophilia.—In *Le Sang* C. P. Soulier and M. J. Larrieu described a new antihemophilic factor, factor B. The new factor was found in study of a series of cases of hemophilia, in which two types of hemophilia were differentiated, A and B. The B form is the more serious.

SWEDEN

Campaign Against Poliomyelitis.—In a memorandum to the government, the Swedish Ministry of Health has drawn attention to the prospect of outbreaks of poliomyelitis in the near future and to means for dealing with them. It is feared that, owing to the declining immunity to poliomyelitis, there is a serious risk of severe epidemics in Sweden in the autumn of 1953 or 1954. Provided the dosage of gamma globulin is adequate, it can be counted on to provide some, though not absolute, immunity that lasts at best only five weeks. It is calculated that Sweden can produce not more than 3,000 to 4,000 protective doses from blood and not more than 6,000 to 7,000 such doses from placentas. This prophylactic treatment should be repeated at least three times during each season, if between 4 and 5 million potential patients are to be given adequate protection. But, at present, it is impossible to employ gamma globulin as an all-round prophylactic for the reason, among others, that the cost would be prohibitive. Work is now proceeding with the preparation of a quantity of poliomyelitis virus large enough to assure production of an effective vaccine, but the difficulties are such that it is not likely that wholesale immunization with such a vaccine can be provided before 1956.

The memorandom deals in detail with the measures to be taken with cases of bulbar paralysis hitherto nearly always fatal. Only a few years ago, the mortality in these cases was 80 to 90%. In Sweden it was reduced to 60 to 70% in 1947 and 1948, when operations on the larynx and postural treatment to assure better drainage came into general use. The latest figures show that in Sweden practically two-thirds of these patients may be expected to survive largely because teams of specially trained workers can now carry them through the critical period. It is calculated that a maximum of 500 cases of bulbar paralysis requiring respirators or other special devices will have to be dealt with yearly. To this end some 250 respirators, or similar contrivances for artificial respiration, will be needed on the assumption that the average duration of respirator treatment is about two months. While in such a comparatively densely populated country as Denmark cases of bulbar paralysis are concentrated in only 3 special centers equipped to deal with them, thinly populated Sweden will need 10 or 11 such centers distributed throughout the country. They must be staffed by highly specialized persons serving in mobile units. It is anticipated that much use will be made of air ambulance services including helicopters. The authorities in Denmark, Norway, and Sweden have already arranged to cooperate in this field.

In a report on the prophylaxis of certain infections by gamma globulin, Dr. Rolf Lundström, who is attached to a children's hospital as well as to the state bacteriological laboratory, notes that a Swedish preparation is already on the market but available only in small quantities in connection with measles, hepatitis, and poliomyelitis. As Vahlquist showed in 1951, with a dosage of 0.05 to 0.2 ml. per kilogram of body weight, this Swedish preparation of gamma globulin has a good mitigating effect in measles. Since the available quantity of Swedish gamma globulin is quite inadequate for dealing with poliomyelitis alone, there is no prospect of testing this remedy on scarlatina, which can now be successfully treated with penicillin.

Follow-Up of Prefrontal Leukotomies.—Between Aug. 23, 1948, and April 24, 1951, prefrontal leukotomies were performed by the surgical department of a hospital in Vadstena on patients whose subsequent fate has been investigated by Dr. J. Kryger and Dr. Niels A. Thorn, who review their findings in *Hygiea,* now incorporated in *Nordisk Medicin,* June 12, 1953. The results were not so encouraging as those of several other observers; only three of the patients were restored to normal working capacity, while seven were taken charge of by their relatives. Twelve were able to be transferred to homes for the aged, and 47 were rendered more amenable to institutional treatment. There remained as many as 43 for whom no improvement could be claimed and 2 who were worse after the operation. Eight patients died after it. A comparison of these rather meager results with the achievements of W. Freeman and J. W. Watts and those of I. Blomquist and his associates in Scandinavia gives the impression that the fate of the patient depends largely on the quality of the postoperative treatment and the care taken in reeducating each patient. The patients in the group described were, for the most part, transferred immediately after the operation to a hospital department not providing the necessary rest and quiet or adequately trained personnel. If this shortage of highly trained personnel had been overcome, the results would undoubtedly have been much better.

Spinal Anesthesia.—Recent articles in the Scandinavian medical literature show how contradictory are opinions on the merits of spinal anesthesia. In the spring of 1952, Dr. Ored Arner published a study from the Caroline Hospital (Karolinska Sjukhuset) in Stockholm. His advocacy of spinal anesthesia was based on a follow-up study of patients treated in that hospital in 1949 and also of the patients undergoing spinal anesthesia in the same hospital in the 10 year period 1940-1950 when spinal anesthesia was administered 21,230 times. He came to the conclusion that the complications occurring during or after spinal anesthesia were negligible and that neither their character nor their frequency justified any restriction in its use. He was skeptical as to the correctness of the accounts recently given of complications following spinal anesthesia, and he was in favor of adopting it in outpatient departments.

On the other hand, a monograph published on this subject in 1947 by Dr. Gunnar Thorsén gave a very different picture. In the organ of the Swedish Medical Association, *Svenska Läkartidningen,* June 12, 1953, he has returned to the charge, taking up cases one by one in which he and Arner hold conflicting opinions as to the existence or lack of a causal relationship between disasters and spinal anesthesia. It is evidently often difficult to decide this knotty point. Another approach to a solution of the problem is the study of the popularity of spinal anesthesia in different hospitals from year to year. In Arner's opinion, the number of spinal anesthesias performed has increased in Sweden since 1947. To check this opinion, Thorsén scrutinized the annual reports of several Swedish hospitals and choose the years 1947 and 1951 as samples. His list of 16 Swedish hospitals gives the number of spinal anesthesias, expressed as a percentage of all the anesthesias, performed in each of these two years. At the Caroline Hospital there has been little change; the figures for the two years are 46 and 40, respectively. But at the large Serafimer Hospital the percentage has fallen from 31 in 1947 to 1 in 1951. At three provincial hospitals the shift is in the opposite direction; at Umeo, for example, it was from 31 to 57%. But on the whole the popularity of spinal anesthesia seems to have declined between 1947 and 1951, and Thorsén argues that this decline would be found to be still more marked if a year before 1947 and a year after 1951 were used as test years. His disapproval of spinal anesthesia is also voiced in his argument that it implies residence in hospital, whereas alternative anesthetics may render such residence superfluous.

CORRESPONDENCE

TRANSVESTISM

To the Editor:—The use of surgery to minimize the difference between a patient's appearance and the appearance for which he has a neurotic craving is a novel suggestion. In their paper "Transvestism: Hormonal, Psychiatric, and Surgical Treatment" (*J. A. M. A.* **152**:391 [May 30] 1953), Hamburger, Stürup, and Dahl-Iversen propose that plastic surgery be employed to resolve such a discrepancy even in cases in which there is no objective anomaly or deformity that requires correction. If such a procedure is seriously proposed, it requires serious discussion. In discussing the etiology of transvestism, the authors suggest that it is a form of biological intersexuality. In their view, then, the surgical intervention they suggest consists actually of correction of an anomaly. It has not proved possible, to date, to associate the appearance of traits, mannerisms, or behavior patterns characteristic of one sex in persons of the other sex with any objective physical findings, either clinical or laboratory. On the other hand, endocrine dyscrasias, when they affect sexual desire and performance, merely diminish them; they do not pervert them. Physical hermaphrodites and pseudohermaphrodites seldom show overt mixtures of sexual traits or overt perversions. They usually adopt quietly the behavior appropriate to the sex that is assigned to them by their parents rather than to what might be called their biological sex, namely the sex as determined by the gonads.

In their discussion of their patient in particular and of the problem of transvestism in general, the authors adopt rather uncritically the patient's own formulation of his difficulties. The authors and their patient say that transvestites are unfortunate persons on whom a cruel fate has forced somatic sexual characteristics inappropriate to their respective psyches. This trick of fate makes these patients neurotic. This position is consistent with the biological hypothesis mentioned above, but it is a difficult one to maintain. The authors emphasize that the patient wishes to live as a woman. The data they present clearly show, however, that this is not true. The patient has no desire for sexual relations with men. There is no evidence of any maternal interest. To whatever extent one may judge from the material reported, it seems that the patient's only concern is to *look* like a woman; he does not wish to play the role of a woman in any other way. In other words, he has no interest in his social or sexual performance as a woman but, rather, wishes to *see* and *exhibit* himself as a woman. The authors do not clearly state why they consider the patient's neurosis the consequence of the frustration of his desire to be a woman. They seem to have made no effort to rule out the possibility that this desire is a symptom of his neurosis.

It is an important part of the authors' position to affirm that "The wearing of women's clothes in these cases does not aim at, and does not involve, any sexual gratification. . . . On the whole, the sexual life generally plays but a minor part." It is difficult, however, in the case presented, to accept the proposition that the sexual life really does play a minor part. The person whose problem is reported seems to have spent the major part of his constructive efforts to effecting a change in his apparent sexuality. The authors evidently mean sexual intercourse when they use the term "the sexual life." Further, if the exhibition of the male body in women's clothes (and external appearance) is single-mindedly pursued and if sexual intercourse is avoided, then one may infer that sexual gratification is obtained via exhibition rather than by intercourse. The patient's attitude toward sexual contact, homosexual or heterosexual, seems to be a neurotic aversion rather than a simple disinterest. A transvestite, whom I have known, dresses himself in women's undergarments and masturbates while gazing at himself in the mirror.

The following proposition would seem to me more reasonable. This patient, and every male transvestite, has a neurosis. One symptom of the neurosis is the wish to view and exhibit himself as a woman. The neurosis, however, causes pain. Some of the pain arises from the guilt and anxiety inherent in the neurotic process itself. Another source of pain is the frustration from and resentment against social and legal interference with the gratification of the neurotic wish. If such a man can have his genitals removed, he will (*a*) gratify his neurotic wish, (*b*) obtain legal sanction for his dressing as a woman, and (*c*) diminish a certain amount of his guilt (probably a minor amount), since he believes that he is no longer pretending to be what he is not. Freud said that neurotic patients seek psychiatric assistance not because they wish to be cured of the neurosis but because they wish to be helped to be neurotic more efficiently; that is, they wish to retain their neurotic gratifications without the necessary neurotic guilt and anxiety. Such a demand is impossible by virtue of the very nature of the neurotic process. In the case under discussion, the patient's refusal to be cured is indicated by his rejection of psychotherapy and by his refusal to accept hormonal treatment in an attempt to "alter his mentality in a masculine direction." One might anticipate, therefore, that the pleasure of the gratification of the neurotic wish will be temporary and that other aspects of the neurosis will make the patient as unhappy as he was before surgical treatment, if not more so. The reaction may commence after a latency of days, weeks, months, or years.

One must ask whether the treatment proposed by the authors is good therapy. Since the authors are not concerned with the patient's neurosis, they do not claim to be treating it and do not seem interested in following its course. Is any other form of treatment available? In a way, this question is irrelevant since the patient would not accept any other form of treatment; few transvestites will, unless they become subject to legal prosecution or become too seriously disturbed by anxiety or guilt. Is psychotherapy worth trying? In my opinion, no psychotherapeutic procedure less than intensive, prolonged, classic psychoanalysis would have any effect. If properly done, it could probably reduce the patient's agitation and the level of his unhappiness. It is not impossible that his major symptoms may decrease in frequency and urgency. If radical and rapid cures are not available, no physician will reject, in any field of medicine, uncertain, protracted, and expensive treatment, as, for example, in the treatment of cancer, leukemia, and chronic vascular disease of heart and brain.

The authors conclude "The patient will be able to move about freely among other persons, without anyone suspecting that this is not a normal young woman, but a male transvestite whose highest wishes have been fulfilled with the assistance of the medical profession and by society." In view of the exhibitionistic nature of the patient's craving, one might guess that merely passing as a woman in obscurity is what this patient would shun. He would probably continue his efforts noisily to demonstrate that a male body may have not only female clothing but a female appearance. The ethical arguments of the authors are difficult to accept or to reject. They lead, however, to a somewhat disturbing reductio ad absurdum. If a patient has a wish to die, should the physician actively comply with the patient's wish or even condone his suicide? Euthanasia has been upheld by some in patients suffering a fatal physical illness; it has not, so far as I know, been seriously suggested in mental illness.

TUBERCULOSIS AMONG STUDENTS

To the Editor:—The problem of the excessive occurrence of clinical tuberculosis among American medical students has been with us a very long time. As your editorial (*J. A. M. A.* **152:**922 [July 4] 1953) indicates, sound, established procedures to reduce the degree of exposure to tuberculosis exist today and have existed for some years. It is professionally inadequate to commend those schools that have developed or are developing comprehensive tuberculosis control programs. We should unequivocally condemn any medical school that exposes its student body to groups of patients who may have undiagnosed tuberculosis. It is inadequate to commend schools that have control programs, unless we simultaneously require from them careful epidemiological studies that will adequately account for the failures under the program (From whence came the 11 cases in the seven schools having control programs?).

It is fitting that the medical profession hold a sincere interest in all research that may elicit an explanation of the nature of immunity to tuberculosis in humans. It is ill-advised to becloud the issues involved in the protection of medical students with matters still under investigation. Incidentally, the sound, established procedures that protect medical students are equally effective in the protection of patients and all staff members in the varied medical school situations. Unfortunately, the soundest procedure is the least well established—the elimination of the undiagnosed case from the teaching hospital environment.

ALLERGY AND PROCAINE HYDROCHLORIDE

To the Editor:—We would like to add our support to H. S. Davis and R. Bryce-Smith (*J. A. M. A.* **152:**477 [May 30] 1953) in their challenging of the conclusions reached by Criep and Ribeiro in their article "Allergy to Procaine Hydrochloride with Three Fatalities" (*J. A. M. A.* **151:**1185 [April 4] 1953). We agree with Davis and Bryce-Smith that other more likely causes of death in these cases have not been ruled out. Also an extensive experience with the use of procaine hydrochloride (Novocaine) as a local anesthetic in over 9,500 hernia operations at Shouldice Surgery, Toronto, Canada, without any evidence of an allergic reaction of minor or serious nature to the drug makes us believe that any such allergic reactions, if they occur at all, must be very rare. The usual dose of local anesthetic used in each hernia operation is between 150 and 200 cc. of 2% procaine hydrochloride. The only reactions we ever noted were of the immediate type in the form of twitchings or mild convulsive movements from which the patients invariably made an immediate uneventful recovery permitting the operation to be performed without further incident and with no postoperative sequelae. We have learned, both clinically and in animal experiments, that if twitchings develop further manipulations will aggravate them and may lead to the convulsive type of reaction. If, on the other hand, all manipulations of the patient are stopped completely for from 5 to 10 minutes, the twitchings do not become worse but usually subside quickly allowing the operation to be carried on in a normal fashion. Since we have increased the preoperative barbiturate sedative to between 2¼ to 4½ grains (0.1 gm. to 0.3 gm.) of sodium pentobarbital (Nembutal) 1½ hours prior to operation, these immediate reactions have been almost completely obliterated. There has been only one mild convulsive reaction in the last 4,500 cases.

For the first 7,000 cases, an intradermal test with 2% procaine hydrochloride was carried out preoperatively. Usually there was no skin reaction, but, in a number of cases, an area of reaction up to 2 in. in diameter developed. Despite this degree of skin reaction, the operations were carried out with procaine as the local anesthesia. In no case was there any suggestion of an allergic or anaphylactic reaction or any increased tendency to the early type twitching reaction. None of the 11 patients in our series who had a convulsive type of reaction had a positive skin reaction; in fact, in each of these cases there was no reaction to the intradermal injection of procaine hydrochloride. Because of this lack of relationship between the intradermal reaction to procaine hydrochloride and the patients' general reactions to it, these intradermal tests have been discontinued as a routine procedure. No epinephrine has ever been used with the procaine solutions in Shouldice Surgery both because this might obscure bleeding points, which might later produce hematomas, and because there is evidence that in some cases the combination can have deleterious effects on the cardiovascular system. Reaction is apparently commoner to epinephrine than to the procaine hydrochloride (Campbell, E. B.: *Canad. M. A. J.* **62:**364, 1950). Our analysis of the cases reported by Criep and Riberio and our experience with procaine lead us, therefore, to believe that the fatalities they reported were actually not due to a procaine allergy.

ULCERATION OF SKIN FOLLOWING USE OF ARTERENOL

To the Editor:—The article by Uricchio, Salenda, and Cutts (*J. A. M. A.* **152:**607 [June 13] 1953) is very timely. It is my opinion that tissue necrosis following intravenous administration of arterenol in the leg veins occurs very commonly. Not only tissue necrosis occurs, but actual necrosis of the vein and concurrent venospasm and arteriospasm of the vessels of the same extremities develop and cause ischemic necrosis of the distal parts of the extremities. As the authors suggest, there was venospasm and also spasm of the vasovasorum causing necrosis of the vessel in their patient. The underlying reason for this, in my opinion, is that the venous circulation of the lower extremities is sluggish and, therefore, results in a higher concentration of the drug in the leg veins. To date, I know of this type of necrosis occurring in the lower extremities after arterenol was given in five cases. My experience in administering the medicament via the veins of the upper extremities has been very satisfactory, and at no time has necrosis of tissue or veins occurred unless there was subcutaneous spillage. This information ought to be widely disseminated because arterenol is very useful and may, under certain circumstances, be life-saving.

AMEBIC PATIENT 13 DAYS OLD

To the Editor:—A baby girl, born on Feb. 8, 1952, had numerous vegetative forms of Endameba histolytica in loose stools examined in our laboratory on Feb. 21, 1952. Numerous leukocytes were seen too. Generally, bacillary dysentery is believed to have a sudden, acute onset, while amebic dysentery is believed to have a long incubation period of months or years. Amebic dysentery appeared in this breast-fed infant by the 13th day of life; the incubation period could not, therefore, have been more than 13 days. We saw by then not only free living amebic forms, three to five per field, but signs of inflammation and pus. On Nov. 28, 1952, the feces of the same baby were again examined in our laboratory, and numerous free living amebic forms were still present. The infant's mother was examined on Nov. 20, 1952, and was found to have free living forms of E. histolytica too.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Sherman Anti-Trust Act in Relation to Medical Society Sponsored Prepaid Medical Care Plan.—This was an action by the United States against the Oregon State Medical Society and others for an injunction to prevent and restrain violations of the Sherman Anti-Trust Act, the Government asserting that a conspiracy existed to restrain and monopolize the business of providing prepaid medical care in Oregon and to restrain competition between physician-sponsored prepaid medical plans. The District Court dismissed the complaint (United States v. Oregon State Medical Society, 95 F. Supp. 103; *J. A. M. A.* 136:1067 [July 14] 1951) and the Government appealed directly to the Supreme Court of the United States.

This controversy, said the Supreme Court, centers about two forms of "contract practice" of medicine. In one, private corporations organized for profit sell what amounts to a policy of insurance by which small periodic payments purchase the right to certain hospital facilities and medical attention. In the other, railroad and large industrial employers of labor contract with one or more physicians to treat their ailing or injured employees. Both forms of "contract practice," for rendering the promised medical and surgical service, depend upon physicians or panels of physicians who cooperate on a fee basis or who associate themselves with the plan on a full or part time employment basis. Objections of the organized medical profession to contract practice are both monetary and ethical. Such practice diverts patients from independent practitioners to contract physicians. It tends to standardize fees. The ethical objection has been that intervention by employer or insurance company makes a tripartite matter of the physician-patient relation. Since the contract physician owes his employment and looks for his pay to the employer or the insurance company rather than to the patient, he serves two masters with conflicting interest. In many cases companies assume liability for medical or surgical service only if they approve the treatment in advance. There was evidence of instances in which promptly needed treatment was delayed while company approval was being obtained and in which a lay insurance official disapproved treatment advised by a physician.

In 1936, five private associations were selling prepaid medical certificates in Oregon and the physicians of that State, alarmed at the extent to which private practice was being invaded and superseded by contract practice, commenced a crusade to stamp it out. The campaign was bitter on both sides. State and county medical societies adopted resolutions and policy statements condemning contract practice and physicians who engaged in it. They brought pressure on individual physicians to decline or abandon it. They threatened expulsion from medical societies, and one society did expel several physicians for refusal to terminate contract practice. In 1941, however, seven years before the present action was commenced, there was an abrupt about-face on the part of the organized medical profession in Oregon. The organized physicians completely reversed their strategy, and, instead of trying to discourage prepaid medical service, decided to render it on a nonprofit basis themselves. In that year, Oregon Physicians Service, one of the defendants in this action, was formed. It is a nonprofit Oregon corporation, furnishing prepaid medical, surgical, and hospital care on a contract basis. After seven years of successful operation, the Government brought this suit against the physicians, their professional organizations, and their prepaid medical care company, asserting two basic charges: first, that they conspired to restrain and monopolize the business of providing prepaid medical care in the State of Oregon and, second, that they conspired to restrain competition between physician-sponsored prepaid medical plans within the State of Oregon in that Oregon Physicians Service would not furnish prepaid medical care in an area serviced by a local society plan.

We find not the slightest reason to doubt the genuineness, good faith, or permanence of the changed attitude and strategy of these defendant-appellees that took place in 1941, said the Supreme Court. It occurred seven years before this suit was commenced and, so far as we are informed, before it was predictable. It did not consist merely of pretensions of promises but was an overt and visible reversal of policy, carried out by extensive operations that have every appearance of being permanent because wise and advantageous for the physicians. The record discloses no threat or probability of resumption of the abandoned warfare against prepaid medical service and the contract practice it entails. We agree with the trial court that conduct discontinued in 1941 does not warrant the issuance of an injunction in 1949. Striking the events prior to 1941 out of the Government's case, the court continued, except for purposes of illustration or background information, little of substance is left. The case derived its coloration and support almost entirely from the abandoned practices. A parade of local medical society members from all parts of the state, apparently reputable, credible, and informed professional men, testified that their societies now have no policy of discrimination against private health associations and that no attempts are made to prevent individual physicians from cooperating with them. Members of the governing councils of the state and Multnomah County societies testified that since 1940 there have been no suggestions in their meeting of attempts to prevent individual physicians from serving private associations. The manager of Oregon Physicians Service testified that at none of the many meetings and conferences of local societies attended by him did he hear any proposal to prevent physicians from cooperating with private plans. If the testimony of these many responsible witnesses is given credit, no finding of conspiracy to restrain or monopolize this business could be sustained. Certainly, the Supreme Court concluded, we cannot say that the trial court's refusal to find such a conspiracy was clearly erroneous.

The other charge, continued the court, is that defendants conspired to restrain competition between the several physician-sponsored organizations with the State of Oregon. Apparently, if a county was provided with prepaid medical care by a local society, the state society would stay out or, if the county society wanted to inaugurate a local plan, the state society would withdraw from the area. No matter what organization issues the certificate, it will be performed, in the main, by the local physicians. The certificate serves only to prepay their fees. The result, if the state association should enter into local competition with the county association, would be that the inhabitants could prepay medical services through either one of two medical society channels. There is not the least proof that duplicating sources of the prepaid certificates would make them cheaper or more available, result in an improved service, or have any beneficial effect on anybody. Through these nonprofit organizations, the physicians of each locality, in practical effect, offer their services and hospitalization on a prepaid basis instead of on the usual cash fee or credit basis. To hold it illegal because they do not offer their services simultaneously and in the same locality through both a state and a county organization would be to require them to compete with themselves in the sale of certificates. Under the circumstances proved here, the Supreme Court concluded, we cannot regard the agreement by these nonprofit organizations not to compete as an unreasonable restraint of trade in violation of the Sherman Act.

Accordingly the judgment of the trial court dismissing the plaintiff's complaint was affirmed. *United States v. Oregon State Medical Society, et al., 72 S. Ct. 690 (1952).*

Cardiac Arrest During Otolaryngological Operations.—Sudden cessation of the heart beat in the operating room can occur with local anesthesia as well as with general anesthesia. The cause of this disaster is a lack of oxygen in the vital tissues, but some of the predisposing factors are the position of the patient, decreased vital capacity, tracheal obstruction, poor oxygenation, anemia, anxiety, insufficient atropine, shock, poor cardiac filling, torsion of the heart, excessive accumulation of carbon dioxide despite good oxygenation, errors of judgment, excessive preanesthetic and anesthetic drugs, and cardiac disease. Frequently, the patient has been given too many drugs and too little oxygen. There are two steps in resuscitation, namely, (1) reestablishment of the oxygen system and (2) restoration of the heart beat. The first step is for an alert anesthetist to place a tube into the trachea and deliver 100% oxygen into the lungs under positive pressure. Once the lungs are adequately aerated, the left side of the chest should be opened and the heart and the intact pericardium squeezed upward against the sternum. If oxygenated blood is being delivered manually to the brain by the hydrodynamic pump, the brain can be kept viable indefinitely. If the heart at this stage is not beating rhythmically, the next step is to insert a large rib retractor, quickly open the pericardium, and immediately resume massage while the operating table has been lowered to about 10 degrees with the patient in the Trendelenburg position. If, after a considerable period of adequate massage, the heart does not start beating, about 4 to 5 cc. of a 1:10,000 epinephrine solution should be injected into the right ventricle and massage continued. If the heart is not in stand-still but in ventricular fibrillation, an electric shock is usually required and should be furnished by a defibrillating machine. The major causes for failure to restore the heart beat are poor aeration of the lungs, ineffectual manual massage, retention of carbon dioxide, and intrinsic heart disease. Planning for the eventuality of cardiac arrest is one of the best ways to prevent its occurrence. An illustrative case of a 5-year-old patient subjected to a tonsillectomy and adenoidectomy under general anesthesia is described. The child made an uneventful recovery.

Preanesthetic Sedation of Children.—Many otolaryngologists avoid sedation because of the danger of depression of the cough reflex and the attendant hazard of aspiration of blood and debris into the lungs. Other pediatricians and psychiatrists believe that undesirable personality changes may be related to inadequate preoperative preparation and sedation. The effects of preanesthetic medication, including atropine and scopolamine alone or in several combinations with pentobarbital and morphine, were studied in 1,500 children subjected to a tonsillectomy and adenoidectomy. The incidence of crying prior to anesthesia could be sharply reduced by the addition of a barbiturate to the belladonna drug. Respiratory depression and cyanosis appeared more frequently if morphine and pentobarbital were included in preanesthetic medication, but no evidence was obtained that reflexes were depressed unduly postoperatively. Scopolamine is a better sedative than atropine. Morphine should not be employed in preparation for tonsillectomy and adenoidectomy because it diminished the respiratory force whenever partial respiratory obstruction occurred in the course of oropharyngeal insufflation anesthesia. A barbiturate can and should be administered. Children less than 5 years old are most disturbed by operation and anesthesia. The facts presented argue that sedatives should be given before children are anesthetized. Preanesthetic sedation may increase the risk of respiratory depression during the operation. With inadequately trained anesthetic personnel, psychic trauma is to be considered of secondary importance and use of sedatives is to be avoided.

Intercostal Dissection and Radical Mastectomy.—Hutchinson feels that the several modes of spread of carcinoma of the breast have been largely overlooked owing to the misconception that the lymphatic system is an autonomous circulatory system until it communicates with the major blood vessels. Blood and lymphatic systems are closely related at the point of tissue-fluid movements. This probably explains widespread blood-borne metastasis in cases in which there is a small early lesion and normal lymph nodes. In the 81 cases under consideration the operability was determined by excision and

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

frozen section study of the primary breast tumor. Supraclavicular lymph nodes with questionable metastases were removed in a few cases. In the absence of supraclavicular metastasis, a Halsted radical mastectomy was done and was followed by an exploration of the first three interspaces to obtain information concerning the dissemination of carcinoma in the lymphatic system outside of the axilla. This is not to be regarded as a treatment of internal mammary spread. It was found that one-fourth of the persons on whom the author operated were exposed to a useless procedure, since fatal metastatic disease had been disseminated more widely than had been realized. He gained the impression that the location of the lesion really makes little difference; if it has a spreading potential, it spreads. In patients whose breast tumors had been recognized for one month or less, 15% had a spread to the intercostal nodes. The author disagrees with Urban, who advises en bloc internal mammary dissection only for lesions of the inner half of the breast, as the region of spread of a given tumor is unknown. Of 18 patients with internal mammary spread, 9 are already dead while 7 are alive but uncured; only 2 remain without signs of residual disease. This indicates the futility of radical mastectomy as a curative procedure when spread to the internal mammary lymphatics has already occurred. If surgical treatment of cancer of the breast is undertaken, it should include the axilla, supraclavicular and retroclavicular structures, and en bloc dissection of the internal mammary chain and of the anterior mediastinal structures. The inability of the surgeon to remove completely the lymphatics and lymph nodes in these areas is obvious. The cancer is incurable if at the time of the initial operation it has extended to the supraclavicular or the internal mammary nodes. Pathologists and surgeons will accomplish jointly more by attempting to recognize and eradicate the precancerous breast lesions than by radical surgical removal of breast cancer.

Spontaneous Intracranial Hemorrhage in Children.—The report concerns spontaneous intracranial hemorrhage in eight children, 15 years of age or younger. Two deaths and six recoveries resulted. Angiomatous malformations were present in the four cases in which the cause was definitely proved. Aneurysm of the intracranial portion of the internal carotid artery was the diagnosis in one other case. The cause could not be established in the remaining three cases. Two deaths were caused by massive and rapid hemorrhage. Spontaneous subarachnoid hemorrhage in children arises as a rule from a congenital vascular anomaly, which is usually angiomatous in nature. Successful treatment depends on accurate localization and surgical intervention. Angiography has been of great value in the diagnosis of these lesions.

Plication to Reduce the Caliber of Vein Grafts.—In the course of their laboratory experiments with venous grafts the authors became aware of the need for a method that would reduce the diameter of an oversized vein graft. The following method was evolved: After the graft was anastomosed and distended with blood under arterial pressure, the diameters and circumferences of the graft and recipient vessel were determined by caliper and string measurements. The amount of reduction necessary was calculated, and the appropriate width of vein wall was measured with calipers. The vein graft was then plicated by means of interrupted Lembert-type sutures placed about 2 mm. apart. By use of oiled 6-0 nonabsorbable surgical (silk) suture material on a sharp atraumatic needle, it was possible to place most of the sutures without penetrating the intima. The sutures were so placed that the entire width of vein wall, which was infolded, was encompassed by each stitch. The authors got satisfactory results with this method in reducing the diameter of fresh inferior vena cava autografts implanted into the abdominal aorta of 10 adult dogs and 12 weanling pigs. Similar groups of animals with unplicated grafts were used as controls. Examination of the plicated segments of vein grafts from seven days to six months after operation revealed that the sutures were covered by endothelium, the vessel walls were thickened, and the line of plication was barely discernible. The incidence of thrombosis in plicated grafts was greatly reduced.

When Should a Retarded Child Be Institutionalized?—Earlier institutionalization of the severely retarded child has been the trend for the past 15 years. While the total of first admissions and the total number of patients have increased gradually by less than one-third, first admissions before the age of 5 have almost tripled. Jolly feels that this trend is largely due to earlier recognition and to advice from physicians for immediate institutionalization. It has been economically impossible, however, to provide additional crib facilities at the rate demanded. Consequently long waiting lists have been built up in most institutions that accept infants and obstetricians and pediatricians should reevaluate their stand on immediate institutionalization. To about the age of 3, the physical care of most retarded children is no greater than that of a normal child of the same age. It is usually better to have the parents work out their emotional conflicts gradually, while caring for the child at home, during the first years of life. Under the guidance of a physician who will take time to explain the possible causes of the defect, give an honest prognosis, and emphasize the positive features of institutional life, the parents will come to accept their misfortune and to see the logic of separation. The request for institutionalization will then come from the parents themselves and will have complete acceptance. The author feels that the optimal time for institutionalization is seldom, if ever, in early infancy.

Tantalum Gauze in Presence of Infection.—Tantalum gauze and wire (both monofilament and braided) cause no trouble in the presence of infection, such as persistent sinus tracts or buried infected granulomas, unless other foreign bodies, such as silk or cotton are also present. If implanted tantalum gauze becomes exposed, granulations will grow through it and the wound will heal spontaneously unless there is an associated dead space. Abundant subcutaneous tissue should be left whenever possible under the skin flaps used to cover tantalum. In potentially infected ventral hernia wounds, the peritoneum should be closed with braided tantalum wire (which does not cut through). Monofilament or braided tantalum wire may be used to suture the tantalum gauze in place. Absorbable surgical suture should be used for ligatures. Silk and cotton should not be used in such wounds (except possibly in the subcutaneous tissue), as they cause trouble in the presence of infection. Drains should be used to prevent the collection of serum in extensive dissection of skin flaps. Koontz used a piece of tantalum gauze in several cases as large as 12 by 12 in. (30 by 30 cm.), almost covering the entire abdominal wall, and obtained healing.

Complete and Incomplete Pulmonary Infarction.—The roentgenographic aspects of pulmonary infarction in 10 women and 15 men between the ages of 9 and 79 years are reported. The pulmonary infarcts in these patients were subdivided into the complete and incomplete types according to the classification of Hampton and Castleman. Of the 25 patients, 22 had the complete type, with a sequence in the involved lung area consisting of filling of the alveoli with blood, while larger units such as the alveolar sacs and atria remain filled with air for as long as 24 hours. At the end of 24 hours necrosis of the alveolar walls and degeneration of the red cells starts. Organization begins in the second week and may last for months until a fibrous scar remains. The incomplete infarct begins similarly, with edema, fluid, and red and white blood cells in the alveoli; this does not progress to alveolar wall destruction and heals by resolution in two to four days. There are both primary and secondary manifestations of complete infarcts. The primary signs are those produced by the infarct itself and the secondary signs by the effects of the infarct. The odd shape of a homogenous density, pyramidal or triangular, round, oval or irregular, was observed in the author's cases, and was helpful in making the diagnosis of infarction. The location is variable. According to reports in the literature, there seems to be a predilection for the lower lobe of the right lung. The author's observations supported this view, the right lung being the site of an infarct two times as often as the left, with the right lower and middle lobes being involved in 44% of the cases. Odd and round shadows may be caused by superimposition of multiple infarcts and should be "dissected" by multiple films, including spot films. The infarct is always in contact with one or more pleural surfaces; the cardiac margin is rounded or "hump-shaped." The long diameter is always parallel to the largest pleural surface involved. Other workers have described secondary signs of pulmonary emboli, such as clouding in the region of the costophrenic angle on the side of the infarct, accentuation of the hilar vessels on the side of the lesion, the presence of a prominent pulmonary conus, and elevation of the diaphragm on the affected side. Some of these signs were observed occasionally by the author, but are usually unreliable. Pleural effusion may or may not be secondary to an infarct. In contrast to the experience by other workers, the pleural effusion observed by the author in six of his cases was not of greater roentgenographic dominance than the parenchymal density; in only one patient was the amount of fluid large, and not even in the latter was the density of the infarct hidden by the fluid. In the three cases of incomplete infarction, faint, sharp, short lines were seen in chest films coincidentally with the clinical occurrence of pulmonary emboli. These were situated transversely or obliquely and were not visible on roentgenograms previously; they changed character in two to seven days. The shadows believed to represent incomplete infarcts occurred in the middle third of the lungs and the bases, were often single, and were not associated with abdominal lesions. The experience in interpreting these linear shadows is limited, and further studies are necessary to verify the author's suggestion. The concept of the incomplete infarct probably overlaps that of the pulmonary embolus without infarction. Embolism without infarction, or probably with incomplete infarction, occurs very frequently; an area of pulmonary ischemia may be a roentgen sign of this situation, as described by Westermark and others. Clinical evidence of a pulmonary embolus associated with negative roentgenographic evidence may also warrant this diagnosis.

Sulfhydryl Therapy of Ocular Burns in Rabbits.—Comparable corneal burns were produced in both eyes of 10 rabbits. Six rabbits received thermal (actual cautery) burns varying in extent from 2 mm. to an entire quadrant of the cornea. The corneas of two rabbits were cauterized with a single drop of 28% ammonium hydroxide applied for 30 seconds and then washed for two minutes with isotonic sodium chloride solution. A similar application of glacial acetic acid was administered to the corneas of two rabbits. All of the corneal burns were quite severe and extended deeply into the stroma. A generous amount of a sulfhydryl compound (Hydrosulphosol) was instilled daily into each right eye of the animal and a comparable quantity of castor oil into the left eye. A binocular pressure bandage was applied daily after the instillation of a drop of 30% sodium sulfacetimide in order to prevent the development of extensive purulent ulcers. The daily observation of the control and treated eyes did not reveal any material differences between the course and end result of corneal burns treated with the sulfhydryl compound and the control series. It is possible that a potential hazard exists in the employment of sulfhydryl therapy, inasmuch as anaerobic bacterial growth stimulation and delayed wound healing have been experimentally reported by other workers.

Car Window Fractures of Elbow.—Car window fractures of the left elbow are often referred to as "side-swipe" fractures. Most of them are sustained by drivers of automobiles, while their elbow is protruding from the car window. Children sustain such fractures in school buses or other vehicles. "Side-swipe" fractures range from simple fracture to complete traumatic amputation of the left arm. They include compound fractures of both bones of the forearm, compound fractures of the humerus, comminuted fracture dislocation of the elbow, and avulsion of the elbow joint, including the lower third of the humerus and the proximal portion of the ulna and the radius. At the University Hospital in Augusta, Ga., 20 cases of injuries received while the arm was protruding from the car window were treated over a three year period (1948-1951). In several cases this was not the only injury received, but it was often the more disabling. The histories of three patients with this type of fracture are reported. Counteracting the shock is of primary importance. Thorough débridement, wound irrigation, and administration of tetanus antitoxin and chemotherapeutic agents are other essential measures. Some form of intramedullary fixation or the use of bone screws may be required. For treating fracture of the humerus a hanging cast may be preferable to open reduction. Urging car drivers and passengers not to rest arms on the ledges of their car windows is the most important factor in the prevention of these disabling injuries.

Residual Typhus Fever in Georgia.—In 1937 a typhus control program was organized by the Department of Public Health. The earliest measures employed to combat the disease consisted of rat eradication, rat-proofing of buildings, and promotion of community projects for better refuse collection and disposal. These measures were effective in local areas but few communities participated in the program. In 1945 DDT insecticide dust became available, and with the assistance of federal funds a greatly expanded control program was possible. The application of DDT dust to rat runs, harborages, and burrows was aimed directly at the principal vector, the Indian rat flea (Xenopsylla cheopis). The success of this phase of the program is indicated by the decline in the number of human infections and by a significant drop in the percentage of rat bloods showing murine typhus fever antibodies. The number of reported human cases dropped from 1,111 in 1945 to 58 in 1951, and a corresponding decrease was observed in the percentage of rats with positive blood. The destruction of the domestic rat was made much more effective by the introduction of a new rodenticide. Differentiation between typhus and other febrile diseases is highly desirable because of the control measures required. For instance, although typhus and Rocky Mountain spotted fever usually respond alike to antibiotic therapy and react in an almost identical manner in the Weil-Felix test, the two diseases are dissimilar with regard to the tick vector. They can be definitely differentiated only by means of complement fixation tests. Leptospirosis may likewise be mistaken for typhus unless laboratory tests are carried out. With regard to the prospect of complete eradication of typhus, the authors say that, as with other diseases dependent on a complicated host-parasite relationship for existence, the process of transmission becomes more and more difficult as the number of infected and/or susceptible persons declines. Since rats remain infective for their ectoparasites for limited periods of time, it is apparent that in any given locality some minimum number of rats is required to permit continued transmission of the infection. Thus, when that critical level is passed, it is probable that the disease will rapidly disappear.

Penicillin at Twelve Hour Intervals.—The effects of different regimens of penicillin therapy were studied in 292 children with 308 various common infections considered sufficiently severe to require antibacterial therapy. Eighty-seven were given orally 200,000 units of potassium penicillin G in a liquid vehicle as an initial dose, followed by 100,000 units of the same preparation at intervals of four hours; 103 were given orally 300,000 units of the same preparation at intervals of 12 hours; and the remaining 102 children were given orally 300,000 units of procaine penicillin at intervals of 12 hours. Clinical and laboratory studies showed that patients who received 300,000 units of penicillin every 12 hours responded as satisfactorily as those who received 200,000 units initially followed by 100,000 units every four hours. The effectiveness of procaine penicillin was comparable to that of potassium penicillin G when each was administered in equivalent amounts at intervals of 12 hours.

Respiratory Difficulty in Postmeasles Encephalitis.—The occurrence of a pronounced degree of respiratory irregularity during the acute phase of postmeasles encephalitis is reported in three boys and one girl. Institution of electrophrenic respiration had an immediate effect and permitted the maintenance of adequate gas exchange until normal regulation of breathing could be established. One of the most striking features of the respiratory difficulty in postmeasles encephalitis was its relatively short duration when properly treated. If the patient can be tided over for a few hours, normal breathing is resumed. There is no recurrence of respiratory irregularity once normal breathing has been established. The electrophrenic respirator is a valuable adjunct to the limited therapeutic armamentarium available for the management of the postinfectious encephalitides. Its proper use is unquestionably life saving. Since convulsions appear to be an almost constant antecedent or concomitant finding at the time of respiratory irregularity, treatment to control and stop them must be carried out simultaneously with institution of adequate ventilation. Phenobarbital sodium parenterally in a dose adjusted to the body weight terminated the acute seizure in a short time in most cases. It has been the practice to administer diphenylhydantoin (Dilantin) sodium at the same time and to continue its use for five or six days after convulsions have stopped. Oxygen has always been given. In instances where phenobarbital sodium is ineffective and the patient is in status epilepticus, anesthetization by the inhalation of ether is frequently effective when all other measures have failed.

Pulmonary Resection for Blastomycosis.—Lobectomy was performed on two men, aged 56 and 49 years, with pulmonary blastomycosis; one had a discrete nodular lesion and the other acute progressive disease. Although the correct diagnosis was not established preoperatively in the older patient, early intervention for a lesion suspected of being malignant resulted in eradication of the blastomycotic process while it was still localized. A three month period of complete bed rest was enforced, during which time the patient remained afebrile and asymptomatic and gained 19 lb. (8.6 kg.) in weight. After an additional three months of gradually increased activity, the patient resumed his former occupation as an elevator operator and nine months after the operation he was in excellent health. There was no roentgenographic evidence of recurrent disease. This highly satisfactory result was thus obtained with lobectomy and bed rest alone without postoperative administration of a fungicidal agent. In the younger patient a preoperative diagnosis of bronchiogenic malignancy with secondary infection was favored over that of a primary inflammatory process. There was excellent postoperative reexpansion of the remaining lobes of the right lung. The patient was essentially asymptomatic and was discharged from the hospital on the

24th postoperative day with instructions for modified bed rest at home. Within three weeks fever and cough recurred, and sputum culture was positive for Blastomyces dermatitidis. Preoperative and postoperative use of some of the more effective fungicidal agents now available might have prevented the postsurgical flare-up of the disease process. These two cases are the first to be reported in the literature in which lobectomy was employed in the treatment of pulmonary blastomycosis. Pulmonary blastomycosis may closely simulate bronchiogenic carcinoma in its roentgenographic appearance and must be considered in the differential diagnosis of the latter condition. The excellent results obtained in the older patient suggests that pulmonary resection should be strongly considered in the therapy of some cases of blastomycosis. The prompt recurrence of the disease in the other patient seems to indicate that resection alone does not represent suitable therapy in dealing with intense, poorly localized, progressive blastomycotic lesions. The management of blastomycosis should simulate that of pulmonary tuberculosis. The combined use of drugs and resection might offer more favorable results in pulmonary blastomycosis, just as streptomycin and *p*-aminosalicylic acid combined with surgical intervention have improved the prognosis of tuberculosis.

Treatment of Stress Incontinence in Women.—Wharton describes his experiences in the treatment of 26 women with stress incontinence, all of whom were studied medically, gynecologically, and, when necessary, urologically, to determine the causative factors and the most promising methods of treatment. Stress incontinence occurs in a variety of circumstances: in the young and old, in the nulliparous and parous, independently of any other urinary disorder, in the fat and thin, in the presence of senility and neurological disorders, postoperatively, and without respect to any other gynecological disorder. It seems that the sphincter mechanism in women is not particularly rugged, and that its efficiency may be easily impaired by factors that increase the pressure or stress on the full bladder or impair the neuromuscular mechanism of urinary control. Cystoscopy with elimination of local urological disorders such as trigonitis, urethritis, hydroureter, and hydronephrosis was employed by Wharton in six patients. Two were cured and three improved, but the cystoscopic treatment failed in the sixth patient. Stress incontinence of one year's duration disappeared spontaneously without any treatment in one patient; two others who received no treatment were not improved. Weight reduction effected improvement in two of the patients. Exercises were used exclusively or as the chief therapy in 19 cases, and for 15 of these, enough time has passed to warrant drawing conclusions. Six patients have been cured, five have been improved, and four have not been noticeably benefited. The exercises consist solely in the voluntary tightening of the vesical and rectal sphincters, as recommended by Kegel. The patient is told to contract the vesical sphincter just as if she were trying to prevent the escape of urine; at the same time she is to contract the rectal sphincter as if she were trying to prevent the escape of gas or fecal material. In Wharton's experience, one can explain these exercises by verbal directions, without demonstrating these muscles. Furthermore, he feels that the Perineometer (a device for measuring the force of contraction of perineal muscles), which was formerly used in the exercise treatment, is a useless encumbrance. Improvement in urinary control is usually evident within a month after the exercises are begun. If stress incontinence is accompanied by gross gynecological disorders, such a prolapse of the uterus or vagina or large pelvic tumors, these disorders should be corrected by surgical means. At the same time, if feasible, a Kelly plication of the vesical sphincter should be done. When, however, there is no significant gynecological or urologic disorder, the stress incontinence should be treated by exercises designed to strengthen the sphincter mechanism and by accessory medical or urologic means as indicated.

Confusion with Carcinoma of Prostate of Granulomatous Prostatitis.—Thompson and Albers found that in a number of cases in which a preoperative diagnosis of carcinoma of the prostate gland was made, microscopic examination of tissue resulted in the diagnosis of granulomatous prostatitis. With the aim of clarifying the confusion existing between prostatic carcinoma and granulomatous prostatitis and to uncover symptoms and laboratory findings that might indicate the latter diagnosis preoperatively, they obtained at random the records of 36 patients who had received the pathological diagnosis of granulomatous prostatitis, and who had undergone transurethral resections at the Mayo Clinic during the period from January, 1943, to September, 1949, inclusive. No attempt was made to study every case of granulomatous prostatitis in the records of the clinic. In these 36 cases, the preoperative diagnosis of carcinoma of the prostate or probable carcinoma of the prostate had been made 20 times and benign hypertrophy 16 times. The authors describe six cases that illustrate various phases of granulomatous prostatitis. They include two patients who had eosinophilic granulomatous prostatitis. This study reveals nothing in the history or physical findings that can be used as positive evidence to differentiate malignant disease and granulomatous prostatitis. It seems likely that this condition occurs oftener than is recognized and that some patients with this benign condition are in danger of being treated for carcinoma of the prostate. The use of hormonal therapy, such as the administration of diethylstilbestrol, and especially the use of surgical castration, must not be considered in the absence of evidence of carcinoma in biopsy specimens or in the absence of roentgenologic evidence of carcinoma of the prostate. Granulomatous prostatitis can produce a consistency of the prostate identical to that produced by carcinoma and, unless tissue is examined microscopically, the proper differential diagnosis cannot be established.

Tracheal Obstruction from Benign Lymphoid Hyperplasia.—The chief complaints in a girl, aged 2½ years, were gasping for breath during exercise, a change in voice, and noisy breathing while sleeping. The mother stated that the baby had developed noisy breathing during the second week of life and that this gradually became worse. When the baby was 3 months old, the parents consulted a pediatrician. Chest roentgenograms in July, 1949, were said to have revealed enlargement of the thymus gland. Three x-ray treatments were given at that time, but no significant improvement in symptoms was noted. When the child was first seen by Olson in February, 1952, the voice had a "tinny" sound. Respiratory distress was noted when the child was allowed to run around in the office. A scout film of the upper airway revealed narrowing of the upper trachea as it merged with the larynx. The lumen of the trachea at this point was reduced to one-third of normal size by a mass arising from the posterior wall of the trachea. The child was hospitalized, and direct laryngoscopy was performed with the child under light general anesthesia. A rounded, smooth, nonulcerated mass of firm consistency and with a broad base was seen in the posterior wall at the cricoid level. A 3.5 mm. bronchoscope could not pass the obstruction. Tracheotomy was performed on Feb. 29, 1952. The tube was inserted at the level of the seventh and eighth tracheal cartilages. A 5 mm. bronchoscope was then introduced and specimens of tissue were removed for microscopic examination. The child was returned to the ward in good condition, but late that evening her respirations became labored. A bilateral pneumothorax had developed, which necessitated thoracotomies and the insertion of a Foley catheter into each pleural space. The dyspnea promptly disappeared. The pneumothorax cleared rapidly, and the Foley catheters were removed after three days. In reviewing all of the pathological material and the clinical history, it was felt that the patient had a benign deposit of lymphoid tissue beneath the tracheal mucosa. The further course was uneventful and the child was well at the time of writing, but only time will tell whether or not subsequent infections will result in recurrence of the mass.

Lipodystrophy Following Insulin Injections.—Loss of subcutaneous fat occurs in diabetic patients receiving insulin; local hypertrophy of the subcutaneous fat may also occur. Paley feels that the term lipodystrophy should refer to all abnormal reactions of the subcutaneous fat to insulin injections, and that loss of this tissue should be termed lipoatrophy. The following causes have been suggested for the disappearance of the subcutaneous fat: trauma due to the repeated injections, low-grade inflammation, tricresol used as a preservative in insulin, the assumed lipase content of insulin, the strong initial concentration of insulin, and local sensitivity to insulin. Few of these possibilities have been supported by fact. Data were collected during the years 1947 to 1950, when diabetic patients with dermal reactions to insulin were studied at a diabetic clinic in Leeds, England. Lipoatrophy developed in 102 of 186 diabetic patients (54.8%) in whom insulin therapy was started at the Leeds Clinic between 1947 and 1949, by far the highest recorded incidence of this complication. It occurred in 25.5% of the males and in 64.7% of females. The lipoatrophy was very slight in 45% of those affected, moderate in 39%, and severe in 16%. In the 77 patients in whom the time of onset of lipoatrophy was known, it was 269 ± 36.9 days from the first injection. Patients using protamine zinc insulin had a significantly higher incidence than those receiving soluble insulin. Patients originally showing dermal reactions to insulin were most likely to suffer subsequent atrophy. Spontaneous improvement occurred in almost 30% of the patients with this complication irrespective of the type of treatment. The exact cause of the abnormality is still unknown, and therefore no rational therapy is available.

Mortality of Surgically Treated Acute Appendicitis.—The mortality of acute appendicitis was determined in 2,212 patients treated surgically in a small general hospital between 1936 and 1950. Of the 2,212 patients, 738 were treated between 1936 and 1940, representing the presulfonamide era; of the 738 patients, 28 died, a mortality rate of 3.8%. Nine of 891 patients died who were treated between 1941 and 1945, when sulfonamides were used, a mortality rate of 1%. Of the remaining 583 patients treated between 1946 and 1950, when both sulfonamides and the antibiotics penicillin and streptomycin were used, 3 died, a mortality rate of 0.5%. The majority of the deaths were due to peritonitis, and the present favorable results were attributed to the use of antibiotics and sulfonamides in treatment. The incidence of gangrene and perforation remained essentially unchanged during the 15 year period.

Correction of Rectal Procidentia.—The occurrence of rectal procidentia in the sense of abnormal descent of all the coats of the rectum with protrusion through the anus as a large mass in the intergluteal region is reported in three women between the ages of 68 and 75 years. The Thiersch operation designed to diminish the size of the anal canal by means of a nonyielding wire cuff, thus obtaining a mechanical barrier to the prolapsing mass of tissue, was performed with local anesthesia in all three patients. There was little postoperative pain. Hot boric acid compresses or hot sitz baths offered satisfactory relief from discomfort. A daily enema is required indefinitely to prevent fecal impaction. There were no complications or recurrences in any of the three patients at 10 months, 9 months, and 4 months after the operation. Despite the fact that the wire became loosened in one patient, there was no recurrence. The Thiersch operation is a simple palliative procedure recommended for the correction of rectal procidentia in the elderly, debilitated patient. Performed with local anesthesia, the operation requires about 15 minutes. The author's patients have been restored to a normal existence.

New Mercurial Diuretic for Oral Administration.—A new mercurial diuretic for oral use, chlormerodrin (Neohydrin) was given to 33 patients with congestive heart failure, all of whom had previously received meralluride (Mercuhydrin) injections at least once a week and were maintained with digitalis therapy and a low salt diet. Four patients stopped medication because of unpleasant side-effects. One patient stopped taking the drug because he did not show improvement, but after one month started again and became fully compensated. Twenty-eight patients tolerated the drug well for from 2 to 12 months. All signs and symptoms of congestive heart failure disappeared. No meralluride injections were necessary in this group. The most effective dose was one tablet of chlormerodrin (10 mg.) three or four times a day. With chlormerodrin therapy, the maintenance of cardiac compensation and improvement in tissue nutrition is also accompanied by a marked restoration of confidence and well-being.

Generalized Dermatosis Caused by Dental Infection.—A man, aged 28, reported that while he was in the Army he had two attacks of vesicles and bullae of his hands and feet that later became generalized. They oozed and were finely crusted and erythematous, and there was swelling of the face, necessitating many weeks of hospitalization. The present attack began as an itchy erythema of the back of his hands and of his neck. Immediately after this he noticed blisters of the hands, and three days later his face became swollen and was covered with a fine crust. During this period the eruption became generalized. Later he had several similar attacks following tooth extractions or other dental care. He was tested with the penicillin and the anesthetic employed by the dentist, but reactions to both were negative. It was concluded that the eruption was due to a skin sensitivity to the organisms involved, and it was decided to desensitize the patient with an autogenous vaccine. A culture from material from a peridontal pocket grew a pure strain of microaerophilic alpha hemolytic streptococci. The autogenous vaccine was prepared from organisms that had been treated with tricresol. A course of graded subcutaneous densensitization injections was given. This case, the authors suggest, was one of "generalized toxic eruption," possibly with an erythema multiforme bullosa of the extremities. Several points argue against this diagnosis. The eruption followed immediately after dental work on six separate occasions, sometimes within three hours. Following desensitization nine teeth were extracted with only one reaction, which followed an unusual amount of trauma. This seems fairly conclusive proof that this dermatitis was caused by the temporary bacteremia resulting from dental work in the presence of skin hypersensitivity to the cultured organism.

Varicose Veins, A Chronic Disease.—Varicose veins form part of a hereditary syndrome of generalized fascial weakness. The tendency toward the regrowth of varicose veins is inborn and cannot be eliminated by any known method of treatment. Not a single permanent cure has been secured by either surgical treatment or injection, or by any combination of these methods, in the experience of 20 years. Many reports of favorable results are based on an insufficient follow-up; recurrences have sometimes been observed as long as eight years or more after apparently successful treatment. Lymphedema is a frequent complication of vein surgery and should be studied more carefully; if lymphedema is found to occur in a significant proportion of cases, it will be necessary to conclude that surgical treatment of varicosities is inadvisable. The venous circulation is abundantly supplied with secondary channels and this safety factor, which protects the body in the event of trauma, works against any successful treatment of varicose veins; the reaction produced by therapy aimed at their elimination is the same as that produced by injury. Communicating and anastomotic changes immediately begin, and fresh varicosities may appear in the newly developed secondary circulation. Conservative treatment by sclerotherapy remains the treatment of choice, but since the condition is chronic, it can only be held in check by periodic examinations and supplementary injections as needed. No patient should ever be discharged as cured.

Urethral Spasm Preventing Withdrawal of Catheter.—Three patients, one with spastic paraplegia and two with benign prostatic hypertrophy, were subjected to urethral catheterization for routine residual urine determination. Severe urethral spasm was initiated by the procedure and made withdrawal of the catheter impossible. Experience in the first case, in which the catheter was actually broken off at the external sphincter so that the remaining portion had to be removed with a foreign-body forceps, showed that some method of securing complete relaxation of the urethra was needed to solve the problem. External heat, antispasmodic drugs, general or block anesthesia, and various other methods might be used, but since the cases reported occurred in the office and rectal diathermy was readily available, it was tried in the other two cases and proved successful.

New Nerve Pathway for Ménière's Disease.—Rosen demonstrates that Ménière's disease is not localized exclusively in the internal ear but that other nerve structures and pathways are involved. Patients in whom the isolated chorda tympani nerve was subjected to electrical stimulation under local anesthesia reported hearing such sounds as "hissing, buzzing, roaring, ringing, and bubbling," and some experienced vertigo similar to that of Ménière's disease. Hearing and vestibular functions were preserved in 14 patients with Ménière's disease after sectioning of the chorda tympani alone or together with Jacobson's tympanic plexus. Vertigo ceased in 11 patients and persisted in two. Tinnitus disappeared in one, in seven it was no longer annoying, and in six it was unaffected. In one patient in whom the chorda had been sectioned three years before, the hearing returned to a useful high level and remained so, and tinnitus and a sensation of fullness were almost absent. The author points out that the chorda tympani nerve continues upward from the geniculate ganglion as the nervus intermedius. The chorda tympani and the nervus intermedius are a part of the same sensory system, and may be regarded functionally as one nerve, namely, the chorda intermedius. The intermedius communicates with the vestibular branch of the eighth cranial nerve in the internal auditory canal, then continues centrally to join the tractus solitarius, and ends in th seventh sensory nucleus in close relationship with the vestibular and cochlear nuclei. By this pathway, impulses along the chorda intermedius could affect the vestibular function peripherally and both vestibular and cochlear functions centrally. This pathway explains the results of chorda tympani stimulation (vertigo and tinnitus), and also the cessation of vertigo and relief of tinnitus following section of the chorda tympani in Ménière's disease. The author describes two patients with severe Ménière's disease in whom section of the chorda tympani was followed by cessation of vertigo and almost complete cessation of tinnitus. Rosen feels that the discovery of this new pathway will stimulate further investigation and may in turn reveal other structures involved in Ménière's phenomenon. Sectioning of the chorda tympani eliminated vertigo and relieved tinnitus in Ménière's disease, while preserving hearing and vestibular functions.

Fatal Anaphylaxis Following Administration of Penicillin to Asthmatic Persons.—The author reports two fatal cases due to anaphylaxis following intramuscular injection of penicillin in patients with long-standing bronchial asthma and previous sensitization to penicillin. The first patient complained of tightness in her chest three minutes after she had been given an intragluteal injection of 300,000 units of aqueous procaine penicillin. Despite administration of epinephrine, she died five minutes after the penicillin had been given. She had had bronchial asthma for many years, and had been hospitalized for treatment on nine separate occasions, several times in status asthmaticus, requiring injections of ether in oil. She had received many injections of penicillin solution for attacks of sinusitis and pharyngitis. During the past year she had received aqueous procaine penicillin 300,000 units on three or four occasions without ill effect, but there was a history of allergy to penicillin in oil. The second patient was a 63-year-old man with asthma and bronchiestasis of long standing. He had received aerosol penicillin prior to 1947. In December, 1951, he was given an intramuscular injection of 400,000 units of crystallin penicillin and 0.5 gm. of streptomycin in distilled water. Following this he complained that he was having great difficulty in breathing. He had a convulsion and died 8 to 10 minutes after the injection. In case 1 autopsy showed hyperventilation of all pulmonary lobes, with changes similar to changes in anaphylactic death of guinea pigs and in contrast with those usually seen in dogs, rabbits, and humans. Of greater interest still is the unusual paucity of microscopic alterations. If knowledge of the clinical history and the circumstances surrounding the death had been lacking in case 1, it is questionable whether a diagnosis of anaphylaxis could have been made unless it were based on the gross appearance of the lung. Examination of the organs in case 2 established an allergic tendency, because of the marked eosinophilic infiltration in the lungs, the spleen, and the bone marrow. Another point of interest is the absence of smooth muscle hypertrophy of the bronchial walls in both cases.

Action of Candicidin on Pathogenic Fungi.—The water-soluble fraction of candicidin was tested for antifungal activity in vitro against rapidly growing yeast-like fungi, such as Cryptococcus neoformans and Candida albicans, and against slower-growing fungi, such as Histoplasma capsulatum and Coccidioides immitis. It was found to have strong antifungal activity in vitro against the major fungus pathogens of man, with the exception of C. immitis and the ringworm fungi. In experimental fungus infection in white mice the different lots of candicidin available varied in antifungal potency and in toxicity, presumably because candicidin is still an impure substance. The results must, therefore, be considered as provisional. The preparations of candicidin used in these experiments afforded marked protection in moniliasis, blastomycosis, and sporotrichosis of mice. There was a significant but perhaps not strikingly protective effect in histoplasmosis and torulosis under the conditions of the experiment. The course of experimental coccidioidomycosis was not affected by this antibiotic. Candicidin appears to be a promising therapeutic agent because it possesses both fungicidal and fungistatic properties, but in its present state of purification, candicidin is too toxic to be injected subcutaneously or intramuscularly. Preliminary studies have shown that it is not absorbed orally. In humans the only possible route of administration would be intravenous infusion of dilute solutions by slow drip. A potential use of candicidin would be the prevention of development of a yeast-like fungal flora in the gastrointestinal tract of those receiving such antibiotics as aureomycin, oxytetracycline (Terramycin), and chloramphenicol. The simultaneous administration of candicidin with the orally administered antibacterial antibiotics may possibly suppress the development of a Candida flora. Preliminary studies in mice indicate that this is possible.

Poliomyelitis Virus in Human Blood.—Poliomyelitis virus was isolated from the blood of four children in one family during a poliomyelitis epidemic in Ohio in 1952. Three of the children had characteristic clinical pictures of the minor illness or abortive poliomyelitis, and one was asymptomatic. All were found to have virus in the throat and feces as well as in the blood. In none did signs or symptoms of the major illness appear, either paralytic or nonparalytic. As with a similar case that had been reported earlier, all of the children were excreting virus in the stools at the time it was found in the blood. Evidence is thus accumulating that viremia can occur in the human infection as it does in chimpanzees and cynomolgus monkeys, and, as with the latter, it is not associated with the clinical appearance of central nervous system signs but occurs several days earlier in association with the minor illness, or in the asymptomatic infection probably several days after exposure. Whether or not viremia can occur also in the incubation period of the single or double phase illness has not yet been demonstrated. In any event, the presence of viremia early in the course of human, as well as experimental, infection supports earlier hypotheses of rapid virus multiplication outside the central nervous system. Whether this multiplication occurs in neural or non-neural elements is not as yet certain. Different opinions are cited and the authors feel that the problem can only be resolved by demonstrating directly the early presence or absence of virus in various neural and non-neural tissues after administration of the virus by various routes.

Pituitary Tumors in Mice Caused by Propylthiouracil.—Data are presented on four mice treated for 18 months with a diet to which propylthiouracil was added. On examination, three of the four mice had chromophobe adenomas of the anterior lobe of the pituitary. All four mice had carcinomas of the thyroid.

Exchange Rates Between Maternal Circulation and Amniotic Fluid.—The origin, the rate of formation, and the fate of amniotic fluid are controversial subjects. Morphological studies of cellular structures involved did not reveal why large amounts of amniotic fluid are formed in certain pathological states nor could it explain the rapid rate of replacement in the normal pregnant organism as demonstrated by Flexner and his associates. These authors concluded that the amniotic fluid is completely replaced once every 2.9 hours. Such a rapid turnover rate is contrary to the prevailing opinion that the amniotic fluid represents a stagnant pool. Regarding the pregnant organism as a multicompartmented system, the authors decided to determine the exchange rate of the water in amniotic fluid with the water of the maternal and fetal systems. By the application of transabdominal catheters, placed into the amniotic sac of pregnant women at term, amniotic fluid could be withdrawn at desired intervals without disturbing the continuity of the system. The mechanism of tracer (deuterium) exchange was demonstrated to be that demanded by theory, and the application of well-known theoretic equations to the data so obtained permitted the calculation of absolute exchange rates. In two experiments where the isotopic tracer was first placed in one compartment (mother) and then in the other (amniotic fluid), the exchange rates in both directions were found to be about 600 cc. per hour. The observations of Flexner and his associates on the exchange rate of the water of the amniotic fluid are thus confirmed in principle.

Effect of Fly Control on Diarrheal Disease.—In an earlier investigation in Hidalgo County, Texas, flies were shown to be vectors of Shigella infections in an area with a high incidence of diarrheal disease. This paper presents the results of a study, very similar to the Texas study, made in an area of low to moderate morbidity from diarrheal disease. The area is in southern Georgia; its small communities are characteristic of the rural South in size, climate, and agricultural practices favorable to fly breeding, and in community sanitation that allows flies ready access to human excrement. Results of this study demonstrated that during effective fly control in an area of moderate diarrheal disease morbidity, the prevalence rate of Shigella infections and the morbidity rate from diarrheal disease were significantly lowered. Chemical insecticides of the residual type were used for control of adult flies. The development of housefly (Musca domestica) resistance to the DDT initially used resulted in its ineffectiveness in maintaining fly control after 10 months. The dieldrin and chlordane sprays substituted for DDT resulted in excellent fly control for about three months. After that period these insecticides became even less effective than DDT. The fact that the period of effective fly control was the only time during the 32 months of this study that the prevalence rate of Shigella infection was significantly lower in the treated towns than in the untreated towns is convincing evidence that flies were vectors of Shigella organisms.

Climate and Endemic Dental Fluorosis.—The range of fluoride concentration most effective in preventing dental caries was established at approximately 1.0 to 1.5 ppm. These fluoride levels were determined from observations made principally in the Midwest, where mean annual temperatures are approximately 50 F (10 C). A probable relationship between fluoride concentration and climate is now being observed in instituting fluoridation of water supplies. For example, in Wisconsin, 1.3 ppm, is recommended, and in Florida, 0.7 ppm. Studies were made on the prevalence and severity of endemic dental fluorosis in 726 children in six Arizona communities in a desert area, with mean annual temperatures of approximately 70 F, mean relative humidities of approximately 37%, and extremely high daytime temperatures. In these Arizona communities concentrations of fluoride above 0.8 ppm. resulted in objectionable dental fluorosis; concentrations of 0.6 to 0.8 ppm. resulted in an occasional diagnosis of fluorosis; concentrations below 0.6 ppm. did not cause objectionable fluorosis. Arizona children drink more water than children living in more temperate climates because of climatic influences, and as a result, there is increased ingestion of fluoride in relation to the concentration found in the water. Comparisons of the fluorosis indexes in the Arizona communities with those in midwestern communities revealed that fluorosis occurs at about twice the intensity in Arizona than it does in the midwestern area with comparable fluoride concentration but different climatic factors.

Search for Colonic Polyps by High-Voltage Radiography.—Routine proctoscopy and high-voltage roentgen examination of the colon may be expected to show colonic or rectal polyps in approximately 10% of adult patients, regardless of symptoms. Some polyps are malignant when first discovered and others may undergo malignant change; consequently, their early detection and treatment will prevent the development of a substantial number of cancers of the large intestine. The high-voltage technique requires a barium mixture just dense enough to be fully opaque when fluoroscopy is conducted at 80 or 85 kv. A mixture of this density will become radiographically transparent at 120 to 130 kv. The high-voltage radiographic exposure should be such as to show one loop of the colon through another. Polyps will appear as translucent shadows when the density of the barium is properly balanced against the quality of the roentgen rays. Preparation of the patient is extremely important because translucent shadows may also be caused by gas or fecal material. A diagnosis of colonic polyp is made only if the shadow is shown by two separate examinations. Routine use of high-voltage radiography for one year (March, 1951, to March, 1952) in 1,552 patients resulted in the discovery of polyps in 42 (2.7%). Almost the same incidence was reported by Lawrence (2.8% in 7,000 autopsies). Radiography, however, cannot be relied on for the discovery of rectal polyps, which can best be found by proctoscopy. The proctoscopic study may be limited to the length of the rectum and is almost free from discomfort. Its importance may be seen from the fact that when it was carried out as a routine measure in 365 patients, it resulted in the discovery of 28 rectal polyps (7.6%).

Dilute Contrast Mediums in Diagnosis of Lesions of Colon.—Early and accurate diagnosis of small lesions, particularly those of a polypoid type, offers the best hope for successful treatment of cancer of the colon. Statistics indicate that lesions of the colon or the rectum will be multiple in from 30 to 40% of all cases. The finding of a single polyp should lead to a careful search of the entire bowel above the range of direct vision. A good outline of the filled colon, both fluoroscopically and on the roentgenograms, can be obtained by using a contrast medium of lesser density (4½ oz. [135 gm.] of barium sulfate to a quart [a liter] of water with suitable suspending agents) than that ordinarily employed, while at the same time displacement of the medium by small intraluminal masses will be clearly shown on films made with high kilovoltage technique (85 to 100 kv.). Numerous lesions less than 1 cm. in diameter can be detected by this method. The sharpness of the fluoroscopic image with a barium enema suspension of this density depends on the volume of barium distending the lumen. Any region where the bowel will not distend is an area of interest to the examiner and an indication for film studies. Any area of lessened density where the barium is displaced in the lumen of the bowel is considered suggestive of an intraluminal mass; if it appears on the film with similar size, shape, and position or if a pedicle is demonstrated, a polypoid lesion must be considered. The diagnosis should rest on repeated examinations in which the lesion is repeatedly demonstrated. Examination of the colon by this method will not only reveal small lesions but will also show all the other details usually sought for in routine barium enema studies.

Reduction of Ileocecal Intussusception by Hydrostatic Pressure.—Hydrostatic pressure by barium enema, properly used, is the treatment of choice for ileocecal intussusception in infants and young children. It has been used routinely in 27 infants from 3 months to 3 years old during the past two years at the Children's Hospital of Pittsburgh and was successful in 22. Surgery was needed to complete the reduction in four cases, and one child who was in critical condition when admitted died the following day although the intussusception had been completely reduced. Successful use of this method requires the patient to be under constant physical control. A 6 in. (15 cm.) nonelastic bandage is wrapped around the legs; a piece of stockinette of the appropriate size is pulled over the arms; and immobilization is completed by heavy sandbags placed on either side of the body. Retention of the barium enema is assured by inserting an ungreased Bardex catheter, child's size, into the rectum and using adhesive tape to keep the buttocks in close apposition. Neither the patient nor the examiner should be unduly exposed to radiation and the use of adhesive tape makes it unnecessary for an assistant to keep his hand in the field of direct radiation. The immobilized infant is usually quiet and often sleeps during the intervals between recurrent colicky abdominal pains. The gastric contents are aspirated, and a thin barium-water mixture is then allowed to flow into the colon from an enema can 3 ft. (1 m.) above the table. The progress of the enema is followed under fluoroscopic observation. Gentle manipulation may safely be used to aid in the reduction, which is considered complete when the barium mixture flows freely through the ileocecal valve into the terminal ileum. Failure of reflux does not necessarily mean that reduction is incomplete, but if a good flow is absent, the most conclusive roentgen sign of complete reduction is lacking. The clinical condition of the patient is then evaluated and if it indicates that reduction has been completed, 8 or 10 hours may be allowed to elapse before the decision for surgical intervention is made. Operation will be required if signs of intestinal obstruction persist after hydrostatic reduction. Duration of symptoms for more than 12 hours does not in itself contraindicate an attempt at hydrostatic reduction, but caution is needed when signs of intestinal obstruction and shock are present. Dehydration and shock must be treated before any method of reduction is tried. Manifest signs of peritonitis are indications for surgical treatment. Roentgenologists fully acquainted with the clinical aspects of intussusception and expert in the technique and evaluation of its hydrostatic reduction will be prepared, with the surgeon, to assume responsibility for its diagnosis and first treatment; those with less experience should carry out the surgeon's instructions, leaving all important decisions to him.

Fumagillin as an Amebicide.—The crystalline form of fumagillin, derived from Aspergillus fumigatus, proved in in vitro tests to be an effective amebicide both in the presence and in the absence of mixed bacterial flora. In vivo studies in experimentally infected laboratory animals revealed surprising innocuousness and tolerance of greater than therapeutic doses. In tolerance trials on 10 volunteer students, the authors started with daily doses of 10 mg. and increased this by increments of 10 mg. to a maximum of 100 mg. daily. Anorexia occurred with doses of 30 mg., and nausea and abdominal discomfort with 60 mg. Mild diarrhea occurred in some with 70 mg. doses, and mild vertigo occurred in most cases with doses over 60 mg. The authors used fumagillin in 134 ambulatory patients. Requirements for treatment with fumagillin was identification of Endamoeba histolytica cysts or trophozoites in stools obtained by diarrheal defecation, saline purgation, or proctosigmoidoscopy. Three examinations at monthly intervals, including tests on stools obtained by purgation and proctosigmoidoscopic and radiographic evidence of ulcer healing when there was initial ulceration, were required to establish eradication of amebiasis. Sixty-four cases satisfied all requirements and are evaluated. These included 12 cases of acute amebic ulcerative colitis, 18 of chronic amebic ulcerative colitis, and 34 in which there were no symptoms but Endamoeba histolytica organisms were found. In 22 patients in whom amebic ulceration was present on initial proctosigmoidoscopic examination, complete healing resulted. One single large rectosigmoid ulceration persisted but no amebas were present. In nine patients significant roentgenographic findings subsided completely after therapy. Other parasites such as Trichomonas, Trichuris, and Giardia organisms were also largely eradicated, but Ascaris and Strongyloides parasites were not greatly influenced. Endamoeba organisms other than histolytica were eradicated in some patients. The authors conclude that fumagillin is amebicidal for intestinal amebiasis.

Nonmalignant Changes in Gastrointestinal Roentgenograms of Aged Persons.—Pirkey and associates point out that many nonmalignant conditions are often seen in elderly persons. The esophagus is the site of a change in innervation that is manifested in elderly persons by a process known as tertiary contractions. Aortitis with increased tortuosity of the aorta and associated periaortic scar tissue will produce esophageal displacement, which may be sufficient to cause difficulty in swallowing. This is usually on an arteriosclerotic or syphilitic basis. Swallowing of large boluses of food because of dental disorders by older persons is thought to contribute to production of pulsion diverticula of the esophagus. Traction diverticula of the esophagus result from scar tissues pulling on the esophagus from the adjacent lymph nodes at the tracheal bifurcation. The commonest nonmalignant roentgenologic change in the stomach of elderly patients is that of hiatus hernia in which the esophageal hiatus is relaxed and a varying amount of the stomach enters the opening. Duodenal diverticula are very commonly seen on roentgenograms. Diverticula of the jejunum are uncommonly reported. Many elderly patients with vague gastrointestinal complaints have a coarse small intestinal pattern with clumping of the barium and loss of the normal mucosal pattern. This may be due to avitaminosis. Volvulus of the colon may occur, and usually involves the sigmoid portion; volvulus of the cecum is less common. The commonest change seen in the gastrointestinal tract of the aged is diverticulosis. Diverticula are asymptomatic but may be the site of complications, such as inflammation, perforation, fistula formation, and bleeding. Correct diagnosis and the institution of proper treatment in these nonmalignant conditions will frequently be lifesaving.

Parotid Tumors.—Slaughter and associates review observations on 212 patients with tumors of the parotid gland, which included 124 benign mixed tumors (60% of the total) and 55 malignant tumors (26%). About 15% of the parotid swellings investigated surgically were benign lesions not classified as mixed tumors. Thirty-six, or nearly one-third, of the 124 mixed tumors were recurrent after surgical treatment when first seen by the authors. These recurrent tumors were essentially of the ordinary or "average" mixed tumor type, without marked cellularity and with relatively abundant myxomatous stroma and occasional "cartilaginous" areas. In contrast, the malignant tumor group included 12 that probably originated from preexisting mixed tumors. In eight of these for which previous excisional material was available for study, the original tumor was highly cellular, of unusual cell pattern, or of a suggestively atypical cell type, but none of them justified originally a diagnosis of cancer. Recurrence was probably due to incomplete excision, and the growth characteristics of the residual tumor became cancerous. The rare lymphosarcomas and an occasional hemangioma may be indications for radiation therapy, but all other parotid tumors are surgical problems. The authors agree with the modern concept that no benign parotid tumor should be enucleated, but that either a superficial lobectomy or a total parotidectomy should be done. Superficial lobectomy should suffice for the majority of mixed parotid tumors, total parotidectomy being required only occasionally for tumors of the deep lobe. Since clinically innocent lesions may be malignant, every parotid tumor should be identified before the patient leaves the operating room. This means that frozen sections should be examined at once. If an infiltrating malignant tumor is diagnosed, then a total parotidectomy should be performed, with sacrifice of the facial nerve, because if the surgeon does not remove it or any other involved tissue, the tumor will. When cervical node metastases are present, a radical neck dissection should be done.

Treatment of Esophageal Varices by Transesophageal Obliteration.—Crile reported in 1950 preliminary results in seven children and young adults who had bled frequently and severely from esophageal varices and who were treated by transesophageal ligation of the esophageal veins. These patients had normal livers, the varices being the result of a congenital block of the portal or the splenic vein. Since the report, two additional cases have been treated in this manner and the original seven patients have been observed for up to 48 months since the operation. Only two of the nine patients bled after the operation; one had two small hemorrhages soon after the operation and has had none since; the other appears to be bleeding from a gastric ulcer. It appears, therefore, that transesophageal ligation of esophageal varices is safe in dealing with esophageal varices that are secondary to extrahepatic blocks of the portal or the splenic vein, and that in these cases the radical operation consisting of resection of the lower esophagus and the upper part of the stomach, which involve high mortality and morbidity, is not necessary. Transesophageal ligation of esophageal varices is much like a hemorrhoidectomy. The three large veins look like the three large groups of hemorrhoids. The control of bleeding after their obliteration appears to be as complete as after a hemorrhoidectomy. Although hemorrhoids occasionally do recur, the recurrences result from incomplete operation rather than from the formation of new channels. Since a good hemorrhoidectomy usually affords permanent relief, removal of the rectum to control bleeding from hemorrhoids is not considered. If bleeding from esophageal varices can be as readily controlled by obliteration of the esophageal veins, it is hoped that resection of this area will be as unnecessary as removal of the rectum for hemorrhoids. There have been no deaths or serious complications following transesophageal ligation of esophageal veins. The operation has not yet been tried in patients with esophageal varices secondary to cirrhosis of the liver.

*Survey of Typhus in Rats and Rat Ectoparasites in Galveston, Texas. R. W. Strandtmann and D. J. Eben.—p. 144.

Typhus in Rats and Rat Ectoparasites.—A survey of murine typhus among rats and ectoparasites of rats was conducted in Galveston, Texas, from February, 1945, through July, 1947. Only brown rats (Rattus norvegicus) were captured. The complement fixation test on rat bloods gave the following results: In 1945, blood of 63% of 141 rats was positive for typhus; in 1946, blood of 58.8% of 131 rats was positive; and in 1947, blood of 32.7% of 110 rats was positive. The 1947 reduction was probably due to a city-wide DDT dusting program which materially reduced the number of rat fleas. Small lots of ectoparasites brushed off the rats that had been anesthetized with chloroform were inoculated intraperitoneally into laboratory animals to test for typhus. Species tested were the oriental rat flea (Xenopsylla cheopis), the common rat flea (Leptopsylla segnis), the stick-tight chicken flea, the cat flea, Nuttall's rat mite (Laelaps nuttalli), the tropical rat mite (Bdellonyssus bacoti), and the louse. Results showed that the oriental rat flea is probably the chief vector of typhus among rats. Dusting rat runs and rat harborages with DDT materially reduced the number of fleas without materially affecting mites and lice. The reduction in the number of fleas was accompanied by a reduction in the number of rats with positive blood and also a pronounced reduction in the number of cases of human typhus. Seasonal variation in abundance was not apparent in the oriental rat flea, but the common rat flea definitely decreased in late summer and fall. The tropical rat mite also decreased in number during summer and fall, but Nuttall's rat mite was equally abundant throughout the year. Lice were the most numerous and most evenly distributed rat ectoparasites. There was no apparent seasonal variation in their abundance.

Multiple Primary Cancers.—One in 20 patients with cancer of the large bowel seen at the Scott and White Clinic in Temple, Texas, had another cancer in the large bowel either simultaneously or subsequently. In another study of 1,202 patients with cancer of the large bowel, it was found that new malignant neoplasms developed in other organs and sites in 8% of the cases. In the 10 year period ending with 1950, 100 patients were observed with cancer of the bladder microscopically verified, and 39% of these were multiple primary cancers. Of over 5,000 individual lesions of skin cancer observed over a 20 year period, all microscopically verified, multiple primary lesions were observed in 25%. In the bowel, bladder, and skin most cancers are accessible for diagnosis by palpation and modern roentgenologic and endoscopic techniques. Multiple primary cancers may occur in any of the organs named simultaneously, in sequence, or later in separate organs. Recognition of the importance of these facts affects case histories, treatment, and prognosis and is an important element in cancer control.

Experimental Contribution to Study of Methods of Surgical Treatment of Arterial Obliteration. M. van der Ghinst.—p. 271.

Leriche Syndrome: Resection of Aortic Bifurcation.—Obstruction of the aortic bifurcation may occur suddenly as the result of embolism, or it may develop slowly and insidiously as part of a thrombotic process involving the iliac arteries. Ready fatigability and general atrophy of the legs, cramps in the calf muscles, pallor of the feet and legs even in a standing position, absence of a pulse in the femoral or dorsalis pedis arteries, and sexual impotence characterize the syndrome as a whole, but in the early stages of the disorder the symptoms may be so mild that they are disregarded. The progress of the disorder depends on the length of time it takes the obstruction to become complete, the condition of the rest of the arterial system, the relative importance of the compensatory collateral circulation, and possible supervening spasms of the vessels, but sooner or later, unless surgical treatment can be successfully carried out, gangrene will develop. Treatment must be individualized; high sympathectomy gives excellent results in some cases, but is being largely replaced by resection of the bifurcation, procedures designed to remove the clot from the vessels, and arterial grafts. Restoration of the circulation by a graft is the treatment of choice when the arteries are free from lesions, but when atheromatous plaques and calcifications are present resection is indicated. Follow-up of a 51-year-old patient incapacitated by this syndrome who was treated by resection of the bifurcation two and one-half years earlier showed that he was able to work regularly again; he could climb stairs and walk without discomfort; his feet no longer felt cold; and he had gained 8 kg. in weight.

Pathogenesis and Surgical Treatment of Obliteration of Aortic Bifurcation.—Obliteration of the aortic bifurcation may be caused by an embolus; by an obstruction limited to the bifurcation and apparently dependent on a preexisting stenosis; or by the upward extension of obstructions in the femoral and iliac arteries. Embolism of the aortic bifurcation requires immediate surgical treatment if the patient's death from gangrene is to be prevented. Patients with stenosis of the bifurcation usually complain of vague pains in the legs and buttocks on effort or after long walks; they may have subjective hypothermia of the extremities; their sexual potency is sometimes reduced; and wasting is often observed in the muscles of the thighs and pelvis. Aortography shows irregularity at the lower end of the aorta and marked narrowing at the origin of the iliac arteries. These phenomena are probably due to the atheromatous lesions often found in this area. Lumbar sympathectomy at this stage of the disorder may be ineffective and psychologically injurious; a patient in whom complete obliteration of the bifurcation developed after sympathectomy refused further operation and, while still able to live a life of retirement, is incapacitated for work. Surgical treatment, either bilateral sympathectomy or resection of the bifurcation, is most successful when obliteration of the stenotic vessels has taken place gradually, because in such cases the compensatory collateral circulation has had time to develop. Obliteration resulting from ascending lesions may be either rapid or gradual; when it is rapid, the clinical picture resembles that of embolism and bilateral amputation becomes inevitable. Resection with sympathectomy is the only active treatment possible when the extension of the obstructive lesions has been gradual, but the results are often deceptive and the final outcome may be no better than that obtained by letting nature take its course.

Congenital Mitral Stenosis Treated by Valvulotomy.—Congenital mitral stenosis, without any other associated anomaly, is reported in a 9½-month-old boy and with coexistent patent ductus arteriosus in a 5½-year-old girl. Mitral valvulotomy was performed on both patients. The diagnosis was confirmed at operation in both, and also by necropsy in the boy, who died suddenly during feeding 36 hours after the intervention. A history of recurrent pulmonary infection and dyspnea in both patients and of congestive heart failure in the boy was suggestive. A classic presystolic murmur and accentuated slapping first sound confirmed the diagnosis, but these signs were variable so that the diagnosis seemed doubtful. No significant enlargement of the left auricle was revealed by roentgenologic examination. The electrocardiogram showed right ventricular preponderance, which is common at the age of the patients, but it also showed an abnormal P-wave in both cases. Cardiac catheterization was not of direct aid in the diagnosis, but it excluded septal defects and confirmed the presence of a silent ductus arteriosus in the girl besides showing extreme pulmonary hypertension in both patients. Angiocardiography was useful in both patients, by showing a large left atrium with stasis lasting for several seconds in the boy and by showing the ductus arteriosus and the direction of the blood flow in the girl. Selection of suitable cases for valvulotomy is important, since this surgical intervention should add many years to the life of a patient with a well-functioning left ventricle. The commoner condition of unequal division of the common atrioventricular canal may not be benefited. Digital exploration of the stenosed valve was possible in the older patient. An attempt at commissurotomy had to be made blindly by passing a valvulotome through a small incision in the auricular appendage of the younger patient. The latter method can never be so precise as that following digital exploration, but the case of the boy proved that it is feasible. Both these young hearts stood the surgical intervention extremely well.

Fatal Generalized Vaccinia.—A fatal case of generalized vaccinia is reported in an 11-week-old baby girl. Secondary lesions developed around the vulva and the anus and on the dorsum of the left hand two weeks after vaccination against smallpox, and widespread cutaneous lesions appeared on the right hand and the face until death occurred five weeks later. In the course of a normal vaccination, virus-neutralizing antibodies appear in the blood at about 12 to 14 days and continue to rise until about the 21st day, when they attain a steady level. Such neutralizing antibodies failed to develop in the serum of the authors' patient and electrophoretic analysis showed complete absence of gamma globulin. Treatment with penicillin and aureomycin was ineffective, as were transfusions of blood from recently vaccinated donors and intramuscular administration of 750 mg. of gamma globulin. It would seem that hyperimmune animal serums or convalescent serum from a recent case of smallpox should be given in large doses at frequent intervals. The possibility of replacement transfusions should be considered if serum is not available.

Reformation of Mitral Stenosis After Commissurotomy.—The results of commissurotomy depend principally on the condition of the valves—whether they are still supple and only slightly deformed, or have become thickened, rigid, and incrusted, on the degree of inflammation in the tissues, on changes in the chordae tendineae or the papillary muscles, and on the precise location and extent of the newly created aperture. The position of the aperture in the commissural region, the more or less irregular edges produced by the tearing or severing of the valvular tissues, and latent or reactivated inflammatory processes localized in the valves all favor postoperative reformation of the stenosis. Factors relied on to prevent reformation are chiefly the greater amplitude of valvular movement produced by commissurotomy and the resulting increase in the volume and rapidity of the blood flow. Postoperative reclosure of a severely damaged mitral valve was proved at autopsy in the case of a 29-year-old woman subjected to commissurotomy for severe cardiac disability. The postoperative course was uneventful, and the patient's condition was at first greatly improved, but dyspnea recurred on the 15th day and was followed by severe pulmonary edema. Heart failure on the right became pronounced and in spite of treatment with heart stimulants, mercurial diuretics, and anticoagulants, the patient grew steadily worse until on the 28th postoperative day she died. Autopsy showed that the commissurotomy opening in the valve was solidly closed and capable of resisting pressure from a finger trying to re-enter the narrowed mitral orifice. Reclosure was brought about chiefly by organization of a clot superimposed upon inflammatory foci, some of which were old and sclerotic and some quite recent. The authors believe that while the mitral valves probably frequently reclose after commissurotomy, they usually are only partially stenosed, so that most patients derive real, though variable, benefit from the procedure.

Renal Injuries.—Follow-up investigations on 57 patients from 1 to 20 years after they had sustained retroperitoneal renal injuries that were treated conservatively revealed that the late disturbances in the damaged kidney were minimal. The authors feel that early surgical intervention is indicated only if the renal injury is accompanied by increasing pain and tenderness in the flank and by the clinical symptoms of severe hemorrhage, shock, anemia, and a drop in the blood pressure. All other retroperitoneal renal injuries should be treated conservatively. Intravenous urography should be carried out as soon as possible after the accident. Every patient who has sustained a renal injury should be followed up carefully so that suitable treatment can be given early enough in the rare cases in which serious complications arise later.

Recanalization of Thrombosed Arteries.—Thrombosis of the femoral artery was produced experimentally in 14 rabbits. Eight of the rabbits received ethyl biscoumacetate daily by mouth, starting 24 hours after the thrombus was formed. The remaining six animals served as controls. The time required for recanalization in control animals and in animals treated with anticoagulants was recorded by arteriography. Recanalization occurred in the animals treated with anticoagulants in an average of three and a half weeks, while the arteries of the controls were still occluded after several months. The effect of anticoagulant treatment depends on the maintenance of a low prothrombin level. The increased rate of recanalization observed in the treated animals is possibly due to the normally continuous action of fibrinolysin, which is usually masked by the continued deposition of small quantities of fresh fibrin on the thrombus surface. In the presence of an anticoagulant fibrin deposition is prevented. The action of the anticoagulant therefore appears to be indirect. Schmid and Stockinger observed that bishydroxycoumarin (Dicumarol), and ethyl biscoumacetate to an even greater extent, significantly depressed the growth and dividing power of fibroblasts in tissue culture. This effect was present even in the low concentrations found in the blood during anticoagulant therapy. It is therefore possible that the organization of the thrombus is modified by these drugs, and this plays a leading part in recanalization following arterial thrombosis. The conclusion seems justified that adequate prolonged treatment with bishydroxycoumarin in general and with ethyl biscoumacetate in particular has a favorable influence on the reabsorption of arterial thrombi, provided that therapy is started soon after occlusion has occurred. Such treatment may result in reopening of the occluded vessel when the obstruction is due to thrombotic and not to arteriosclerotic changes.

Hematoma of Rectus Abdominis Muscle in Pregnancy.—Hematoma of the rectus abdominis muscle occurs apart from pregnancy, but is found three times more frequently in women than in men. The anatomy of the rectus abdominis muscle plays a part in the causation of the condition. It is divided by ligamentous septa into four muscle bellies, which are enclosed in a strong sheath except at the lower end posteriorly, where the inferior epigastric artery lies relatively unsupported; it is at this level that the hematoma occurred in the most serious cases. The patients affected are usually multiparas, and there has frequently been a rapid succession of pregnancies. Pregnancy is usually well advanced, and hydramnios or some other cause of over-distention of the abdomen may be present. Obesity is sometimes a factor, and muscle tone is usually poor. There is frequently a history of coughing, and chronic bronchitis or asthma may be present. The patient complains of pain on one side of the abdomen that is usually initiated by severe coughing. Diagnosis is difficult. In Torpin's earlier series in many of the cases the condition was diagnosed as a concealed retroplacental hemorrhage, twisted ovarian cyst, ruptured uterus, or ectopic pregnancy. Treatment of the milder cases is usually conservative but pain and progressive hemorrhage may demand active intervention. Forty-five cases of hematoma of the rectus abdominis muscle have been reported in the literature, and four more cases are added. One very severe case was treated by evacuation of the clot from the rectus sheath and the other three were successfully treated by conservative means. There was no maternal mortality, but in the first severe case the fetus died in utero of anoxia. The condition is much commoner than is generally recognized. The minor cases respond well to rest in bed, particularly if the abdominal muscles are well supported and appropriate measures are taken in the treatment of the bronchitis. Surgical treatment should be undertaken early in severe cases or if there appears to be extension of the hematoma. Conservative treatment is more likely to be successful in cases where the upper rectus muscle with its complete sheath is concerned. Treatment of the pregnancy should be conservative, except where gross overstretching of the muscle is interfering with the management of the hematoma, and in such cases induction of labor or cesarean section may be indicated. Undue strain in labor should be avoided, and forceps delivery may be desirable.

Intermittent Acute Porphyria.—The authors report eight cases of intermittent acute porphyria observed in the Edinburgh district in recent years. Seven of the patients were women. The diagnostic difficulties are illustrated by the great diversity of the provisional diagnoses in these cases, e. g., abdominal and gynecological emergencies, nephritis, hematuria, uremia, psychoneurosis, motor neuron disease, and acute anterior poliomyelitis. Attention is drawn to the recurrent association of abdominal pain, constipation, apparent hysteria, peripheral polyneuropathy, and red urine in intermittent acute porphyria, which can be diagnosed by a simple chemical test. In a disease for which no specific treatment is available it is important to avoid drugs such as barbiturates and sulfonamides that may, as in several instances in this series, precipitate or aggravate the condition. Five patients died. The immediate prognosis of intermittent acute porphyria is bad in patients who develop peripheral polyneuropathy; of 5 such patients in this series 4 did not survive. The diagnosis, if not established clinically, cannot be made by the routine methods of autopsy, as the pathological changes both in the central nervous system and elsewhere in the body are indefinite. In the present series three of four patients showed a bluish discoloration of the kidneys at autopsy, but even this might have been disregarded if the diagnosis of intermittent acute porphyria had not been made during life. The condition can be recognized post mortem by inspection of the organs under ultraviolet light, which produces a pink or red fluorescence if porphyrins are present.

Antagonism Between Diabetes Mellitus and Allergic Diseases.—Only 35 of 19,126 patients with diabetes mellitus mentioned in the literature had asthma. Gutmann found 5 diabetics among 2,000 patients with allergy. One patient had both asthma and diabetes, and in two patients asthma and diabetes alternated, so that, when the blood sugar level was above 150 mg. per 100 cc., attacks of asthma never occurred. Although among his 2,000 allergic patients there were only five with diabetes, there were 38 with a diabetic family history. He cites Rost to the effect that diabetic members of families with allergy were free from allergy and vice versa. In trying to explain the antagonism between diabetes and allergy, the author points out that, according to Kylin, fasting blood sugar levels in asthmatic patients are low, between 80 to 90 mg. per 100 cc. Low blood sugar levels were the most consistent findings in 92 patients with intrinsic asthma according to Christensen. Unger found that asthmatics who often have a low blood sugar level seem to be relatively immune to diabetes. Abramson demonstrated hyperinsulinism by six-hour glucose tolerance tests in a number of asthmatics. Derbes and Engelhardt observed temporary relief from asthma following the administration of dextrose. While placing special emphasis on the antagonism of diabetes and asthma, the author also considers other allergic disorders in their relationship to diabetes such as urticaria and Quincke's angioneurotic edema. Four of 12 patients with asthma treated with cortisone and corticotropin had glycosuria and hyperglycemia that made reduction of the doses or interruption of this treatment necessary. These four patients had diabetics in their families, but the remaining eight had no such history.

Diagnosis of Acute Meningitis in Infancy.—Although the prognosis in acute purulent meningitis in infancy has improved remarkably since the discovery and use of the sulfonamides and antibiotics, the fatality rate is still high. One of the factors causing the high mortality is delay in diagnosis. The classical clinical features, stiffness of the neck and spine and Kernig's and Brudzinski's signs, are often absent in the early stages, or may appear at a time when treatment is no longer effective. Increased tension of the anterior fontanelle is a sign of utmost importance, but this, too, may be absent, especially if the baby is dehydrated. Haworth examined the records of the last 50 infants under the age of 12 months who were admitted to Alder Hey Children's Hospital with acute purulent meningitis. The infection was meningococcal in 24 and pneumococcal in 5; in 4 it was caused by Haemophilus influenzae, and in 5 by Bacterium coli; in 12 no organisms were isolated. Most of the unidentified infections were presumed to be meningococcal, many having been treated before admission. The chief symptoms recorded were vomiting, irritability, anorexia, drowsiness, and convulsions. The physical signs were neck rigidity, tense or bulging fontanelle, positive Kernig's sign, and a squint or "vacant look" of the eyes. Thirteen of the 50 infants showed none of the "classic" meningeal signs. Seven of the 13 cases were fatal. The review of the 50 cases supports the view that in infants with meningitis, convulsions signify a grave prognosis. The author makes a plea for routine prophylactic anticonvulsant therapy in this disease. Diagnostic lumbar puncture should not await the development of typical meningeal signs.

Cortisone in Adrenogenital Syndrome.—Franckson and co-workers report observations on six patients with the adrenogenital syndrome before and after treatment with cortisone. The following clinical benefits were observed: decrease of hair growth in one case, regression of masculine physique in three cases, development of breast tissue in two cases, return to normal menses in two cases, and unexpected occurrence of normal menstruation in a case of pseudohermaphroditism. In one case skin pigmentation resembling that of Addison's disease regressed. Excretion of urinary 17-ketosteroids was much reduced in all six patients. Chromatography showed that this reduction affected all the adrenal fractions of the urinary 17-ketosteroids, especially those that were present in great excess.

Assessment of Portal Venous Hypertension by Catheterization of Hepatic Vein.—Paton and associates point out that Myers and Taylor described a method of estimating portal venous pressure by measuring the pressure in a catheter blocking a hepatic vein and by recording pressures from catheters placed simultaneously in the portal and hepatic veins. Paton and co-workers extended the technique of hepatic vein catheterization to study portal venous pressure in patients with liver disease. Fasting patients were given 3 grains (0.2 gm.) of sodium amobarbital (Amytal) 30 minutes before catheterization. Under fluoroscopic control a radio-opaque nylon catheter was passed via the antecubital vein into the hepatic vein. The catheter was then advanced to the periphery of the liver until it met resistance about 10 cm. beyond the mouth of the vein. This was called the "occluded" position. Pressures were then recorded by a strain gage, the zero level being taken at a point 5 cm. below the sternal angle with the patient supine. Blood samples were taken from the occluded position for estimation of unsaturated oxygen, and the catheter was then withdrawn under fluoroscopic control about 5 cm. to the "free" position, where further pressure measurements and blood samples were taken. If possible, the catheter was inserted into more than one hepatic vein radicle to obtain comparable pressure records. Catheterization of a hepatic vein can be carried out in any center equipped for cardiac catheterization. The pressure obtained with a catheter occluding a hepatic vein does not differ significantly from that obtained directly from a portal-vein radicle, unless there is extrahepatic portal venous obstruction. The mean occluded hepatic venous pressure in 24 patients without liver disease was 6.8 mm. Hg. In 11 patients with portal cirrhosis the mean pressure was 22.0 mm. Hg. Raised values were also obtained in two patients with subacute hepatitis and in four patients with congestive heart failure. Normal values were found in 3 patients with extrahepatic portal venous hypertension and in 12 patients with obstructive jaundice (9 extrahepatic and 3 intrahepatic). Theoretical objections to the method do not invalidate its use in the clinical assessment of portal hypertension.

Reactions to Physical Exertion (Stress) in Patients with Bronchial Asthma and Behavior of Eosinophil Leukocytes. L. Koster and C. J. Alers. —p. 940.

Modern Concepts of Poliomyelitis Disease.—Verlinde argues that poliomyelitis can no longer be regarded as an exclusive neurotropic virus disease. Studies carried out during and after World War II proved that the virus is present in the pharynx, the gastrointestinal tract and feces not only in the paralytic, but also in the nonparalytic and abortive forms of poliomyelitis, and even in persons who have had contact with poliomyelitis patients. The majority of the persons who have the disease show extraneural lesions, such as involvement of the myocardium. Myocarditis and myositis may be induced in monkeys by various types of poliomyelitis virus. Hematogenous dissemination has been observed in these animals during the incubation period. Paralysis occurs only following neural spread, which is usually secondary, that is, it originates in the muscle tissue. The bulbar form of poliomyelitis following tonsillectomy, however, is the result of primary neural spread from the port of entry, the pharynx. The occurrence of paralytic forms following inoculation or physical exertion is probably explained by the fact that the virus present in these patients, following hematogenous dissemination, readily invades the muscles weakened by trauma or exertion for secondary neural spread.

The Problem of Syphilitic Balanitis. F. Pagès and J.-L. Freyria.—p. 665.

Pseudomonas Aeruginosa Infections in Children.—Pseudomonas aeruginosa infections are becoming more frequent as a result of changes in microbial flora brought about by the use of antibiotics. Antibiotic suppression of ordinary bacteria enables Ps. aeruginosa, which is resistant to most antibiotics, to develop more readily and to acquire greater virulence than would otherwise be the case. Its presence should never be disregarded, because it may lead to septicemia, meningitis, and necrotic or hemorrhagic lesions in the tissues. Conditions favorable to its development are found in children, especially those weakened by digestive disturbances, dietary deficiencies, or prolonged infections. Experiments on rabbits have shown that syndromes similar to those found in children can be produced by varying the method of inoculation; intravenous injection produces fatal septicemia, subcutaneous administration leads to the formation of eschars, and ingestion causes greenish diarrhea with intestinal ulcerations and necrosis of the liver. Ps. aeruginosa infection in children may be either general or localized; untreated general infections are always fatal. Meningitis is the most severe and persistent localized infection and still carries a high death rate, although antibiotic treatment has produced some improvement. The part played by Ps. aeruginosa in infantile diarrhea is not always clear, but when the bacillus is found in the stools, energetic treatment with diet, rehydration, and combined antibiotics should be instituted at once. Severe necrosis accompanies localized manifestations of Ps. aeruginosa, and when such infections are superimposed on burns, wounds, or eczematous lesions, they delay healing and favor suppuration. Dissemination from local foci may also result in generalized infection. Treatment is difficult, because the bacillus is resistant to most antibiotics in varying degrees; good results, however, can be obtained by using appropriate combinations of antibiotics or antibiotics and the sulfonamides, to which 45% of the strains are sensitive. The antibiotic of choice at the present time seems to be polymyxin B, but it must be used with caution because it has a toxic effect on the nerves and the kidneys.

Icterogenous Hepatitis with Neurological Syndromes.—Direct proof of the presence of poliomyelitis virus in patients with infectious hepatitis and involvement of the peripheral nervous system was obtained for the first time in two of five cases reported by the author. The neurological complications appeared abruptly during convalescence from jaundice in three cases. In one case jaundice followed a surgical procedure in connection with neurological examination, and in the other infection by a neurotropic virus was complicated by jaundice. Recovery from the hepatitis, which was of the usual type, took place in all cases. Regression of the neurological condition was noted in four patients, two being left with minimal sequelae and two with pronounced sequelae. Three years' follow-up of the other patient, however, showed that she still has a neurological syndrome with progressive tendencies. This patient's illness began after a stay at a beach known to be a center of poliomyelitic infection; at the same time, a pet dog that the patient had with her at the beach presented a progressive ataxia and amblyopia. Neurological complications accompanying infectious hepatitis are being reported with increasing frequency and are usually attributed to neurotropic properties acquired by the virus or viruses responsible for the hepatitis. The similarity of some of these complications (meningeal and paralytic, especially) to those found in poliomyelitis suggests that in certain cases infectious hepatitis may be caused by the poliomyelitis virus. Various clinical findings support this theory, and a study is now being made.

Pyelonephritis and Arterial Hypertension: I. Actual Status of Problem. R. Campos.—p. 67.
*Pyelonephritis and Arterial Hypertension: III. General Clinical Study, Prognosis and Treatment. O. Avendaño, M. Plaza de los Reyes and R. Orozco.—p. 74.
*Comparative Toxic Action of Streptomycin and Dihydrostreptomycin on Acoustic Nerve: Late Deafness Caused by Dihydrostreptomycin. R. Velasco L.—p. 79.

Pyelonephritis and Arterial Hypertension.—In a group of 57 patients with arterial hypertension observed by the authors, there were 25 with chronic pyelonephritis. The classic symptoms of diffuse glomerulonephritis were observed in one-half of these patients. In the remainder, hypertension and either urinary infection or edema were present. Renal insufficiency was observed in 15 patients. With antibiotic treatment the blood pressure became normal in 10 of 18 cases, pyuria cleared in 8 of 9, the urine became sterile in 5 of 14, the Addis test became normal in 7 of 13 cases, and the renal function became normal in 10 of 15. The authors conclude that chronic pyelonephritis is a frequent cause of arterial hypertension. The disease advances in four progressive phases: (1) localized focal infection, (2) development of pyelocystitis and lesions of the urinary tract, (3) diffuse glomerulonephritis with reversible lesions, and (4) renal sclerosis with renal insufficiency. The treatment consists of administration of antibiotics and surgical correction of anatomic abnormalities of the urinary tract, if any, in the course of the first, second, or third phases of the disease. In the fourth phase, the treatment is symptomatic only.

Effect of Streptomycin and Dihydrostreptomycin on Acoustic Nerve.—Velasco made a comparative study of the effects of streptomycin and dihydrostreptomycin on the acoustic nerve. Streptomycin given in daily doses of 1 gm. up to a total dose of 100 gm. or more to a large number of patients previously seen did not produce hearing disorders. In some cases it produced vestibular disorders that cautioned the physician to stop the treatment. The subjects of this report are six young adults who were given dihydrostreptomycin for pulmonary tuberculosis or for prevention or control of infection. The drug was given in daily doses of 1 gm. up to a total dose that varied from 28 to 70 gm. in tuberculous patients and from 6 to 8 gm. for prevention or control of an infection. None of the patients had dizziness or vertigo. The vestibular apparatus remained normal in all patients throughout the treatment. Bilateral hearing loss with tinnitus appeared between one and one-half and two and one-half months after discontinuation of the treatment and progressed for six months. The loss of hearing varied from 50% to complete deafness, even in patients who had received only a total of 6 or 8 gm. of the drug. Hearing loss and deafness did not progress after six months, but both conditions were permanent. The author states that dihydrostreptomycin in daily doses of 1 gm. is more toxic for the acoustic nerve than streptomycin in the same daily dose. He concludes that dihydrostreptomycin should be used only in cases of tuberculosis that does not respond to other antibiotics.

Surgical Treatment of Cranial Stenosis.—Intracranial pressure caused by cranial stenosis in a boy of 15 was effectively relieved by a new surgical technique consisting of the creation of movable "cranial ribs." Diagnosis was based on the oxycephalic appearance of the skull and signs of cranial hypertension, which had been constantly increasing since their onset one year earlier. General anesthesia was obtained by intubation with the patient in the dorsal decubitus position and a large trephine opening to permit decompression was made in the temporal region on each side. Four smaller parasagittal openings were then made in the skull bilaterally, each being connected with the large opening on the same side by a cut through the bone made with a Gigli saw. A crosswise cut parallel with the longitudinal sinus was then made to free each "rib" at the top, just enough bone being left to hold it in place, and an additional crosswise cut was placed half-way down each rib to provide further flexibility. The expansion of the skull accompanying the cerebral pulsations following this procedure closely resembled the expansion of the thorax during inspiration. The postoperative course was simple and the patient left the hospital in good condition. Recent follow-up showed that he is now well and free from headaches and ocular disturbances; his skull is more normal in shape; his stature has increased; and he is making progress at school.

*Typhoid Fever Treated with Cortisone and Chloramphenicol. R. Dana, G. Borsoni, V. Corcos and Others.—p. 307.

Typhoid Treated with Cortisone and Chloramphenicol.—The most striking effect produced by combined treatment with chloramphenicol (Chloromycetin) and cortisone in uncomplicated typhoid is the rapid decline in the temperature, which usually falls from 40 C to less than 37 C in from 12 to 24 hours. The pulse rate diminishes as the temperature falls, and at the same time the stupor disappears. Splenomegaly regresses. Complications in this series of 13 patients comprised three cases of encephalitis and one of severe intestinal hemorrhage. Encephalitis was noted in one patient during a relapse that occurred 24 hours after administration of cortisone was discontinued; use of penicillin and streptomycin in addition to the chloramphenicol relieved the clinical signs of the condition in 48 hours. Chloramphenicol and cortisone therapy was discontinued when encephalitis appeared in the other two patients; the authors' usual combined penicillin and streptomycin treatment with whole blood transfusions was substituted and proved effective. An intestinal hemorrhage that had begun in one patient before any treatment was started continued in spite of transfusions after chloramphenicol and cortisone therapy was instituted. Replacement of chloramphenicol and cortisone with the authors' usual treatment, to which in this case oxytetracycline (Terramycin) was added, resulted in cure. Relapses of varying severity occurred in five patients, usually after a period of from three to five days, but ultimate recovery was complete in all cases. Cortisone offers real advantages when used as a supplement to chloramphenicol in the treatment of typhoid.

*Epidermolysis Bullosa: Heredity, Prognosis and Incidence in Denmark. K. Bülow and A. Nørholm-Pedersen.—p. 479.
Respiratory Acidosis and Alkalosis. E. Henriksen.—p. 494.
Oxygen Therapy of Patients with Grave Pulmonary Emphysema and Fibrosis. E. Henriksen.—p. 496.

Epidermolysis Bullosa: Heredity, Prognosis, and Incidence in Denmark.—Bülow and Nørholm-Pedersen collected information on 27 families with 594 members, in 143 of whom epidermolysis bullosa or allied changes were established. There is no causal therapy. Four main forms are differentiated. 1. Epidermolysis bullosa simplex, with dominant inheritance, in most cases persists through life but tends to improve. It was found in 96 of 286 members of 10 families, who live mainly in two places in Denmark, Laesø and Vendsyssel. 2. Epidermolysis bullosa dystrophica differs morphologically from the simplex form and is often incapacitating and combined with other deformities. Inheritance is recessive, but milder dystrophic cases with mainly dominant inheritance are described. It was found in 31 of 200 members of 11 families. 3. Epidermolysis bullosa letalis was found in 9 cases of 67 members of 3 families; there were also two infants who died from congenital malformations. 4. Epidermolysis bullosa, temporary form, is of brief duration and has a good prognosis. It was found in 4 of 59 known members of three families.

*Diabetic Nephropathy Illuminated by Renal Biopsy and Renal Function Tests. C. Brun, H. Gormsen, T. Hilden and others.—p. 513.
Succinylcholine Iodide in Electroshock Treatment. B. Ibsen and G. Paerregaard.—p. 531.
Differential Diagnosis in Physiotherapy. E. B. Hansen.—p. 532.

Diabetic Nephropathy Revealed by Renal Biopsy and Renal Function Tests.—Biopsy revealed diffuse glomerular changes in 6 out of 12 patients with diabetes mellitus, diffuse nodular changes in 4, and completely hyalinized glomeruli with remnants of noduli in 1. In one instance the renal tissue was normal, which invalidated the clinical diagnosis of diabetic nephropathy; the renal symptoms were later found to depend on cardiac insufficiency. In four cases without definite clinical signs of diabetic renal affection glomerular changes were demonstrated; they were diffuse in three cases and diffuse in the nodes in one case. Brun and his co-workers conclude that renal biopsy has a certain diagnostic value in diabetic nephropathy. Its value seems to be limited in differential diagnosis with regard to chronic pyelonephritis. The biopsies apparently support the theory that diabetic nephropathy starts as a diffuse hyalinization in the basal membranes of the glomerulus loops and that the nodular changes are a further development of the diffuse changes. Kidney function tests, which in themselves do not allow definite diagnostic conclusions as to the degree and nature of the diabetic nephropathy, suggest that glomeruli with marked changes due to diabetes in some cases have an essentially greater filtration ability than could be assumed from the histological picture.

Study on Influence of Polycarbonic Acids on Coagulation. S. Greif. —p. 254.
Operative Indications in Idiopathic Dilatation of Esophagus. R. F. X. Pellegrini.—p. 256.
*Herpes Zoster of Tongue and Palate and Its Neurological Complications. H. Stepan.—p. 258.

Herpes Zoster on Tongue and Palate.—The rare occurrence of herpes zoster on the left side of the tongue and on the palate is reported. There was pronounced impairment of taste in the two anterior thirds of the left half of the tongue, i. e., in the area of the lingual nerve, as well as in the posterior third of the tongue, i. e., in the area of the gustatory glossopharyngeal nerve. The patient, a 72-year-old woman, also had peripheral paresis of the facial nerve on the left side. One day before the development of the paresis of the facial nerve the patient had pain in the pinna that irradiated occipitally and towards the angle of the jaw. This pain may be considered as the prodromal manifestation of irritation in the area of the posteriorauricular nerve. This nerve arises from the intermedian nerve, the cells of which are situated in the geniculate ganglion. The most important route of conduction of the sense of taste is through the lingual nerve, the chorda tympani, and the facial nerve to the geniculate ganglion. Many of the tasting fibers are commutated in the geniculate ganglion, and that alone may explain the severe disturbance of gustation in the area of the lingual nerve. The impairment of taste in the area of the glossopharyngeal nerve associated with the spread of the inflammation to the sensory portion of this nerve may be explained by the fact that the ramus communicans, which arises from the geniculate ganglion of the facial nerve or closely posteriorly or even from the large superficial petrosal nerve, may be so strong that the large superficial petrosal nerve appears to be a branch of the facial nerve. The motor fibers of the nervus canalis pterygoidei extend from the facial nerve to the levator veli palatini muscle, the sensory fibers present a connection between the gasserian ganglion and the geniculate ganglion, and the parasympathetic and sympathetic fibers are passing in the palatine nerves to the palate, into the area where the herpes vesicles occurred. The paresis of the facial nerve may be easily explained by the pressure that the inflamed and swollen geniculate ganglion exerted on the nerves. It was the diseased geniculate ganglion exclusively that caused the neurological complications in this rare case.

*Symptomatic Pernicious Anemia in Chronic Poisoning with Chromium. H. Steim and L. Weissbecker.—p. 42.

Symptomatic Pernicious Anemia in Chromium Poisoning.—The occurrence of hyperchromic anemia with hemoglobin levels of 12 gm. per 100 cc. and erythrocyte counts of 2,500,000, leukopenia, reduced number of reticulocytes (0.2%), Hunter's glossitis, histamine-refractory gastric anacidity, and paresthesia in a workman is reported who had been employed for 25 years in a tannery. His work consisted in sorting of half-dry hides that had been pretreated with basic chromium sulfate. Liver function tests did not reveal any impairment of liver function; the serum bilirubin level was not increased. The sternal bone marrow showed typical megaloblasts. The patient had cachexia and islet-like surface defects in the oral cavity and the esophagus, which, in the presence of large amounts of chromium in the saliva and in the urine, completed the characteristic picture of chronic chromium poisoning. The classic symptoms of pernicious anemia prompted the author to give the patient vitamin B_{12} and/or pteroylglutamic (folic) acid orally or parenterally, but the patient did not respond to this treatment. He then was given continued blood transfusions. Six months after the last blood transfusion the blood counts had become normal. The ulcers in the mouth and in the esophagus were cicatrized and the amounts of chromium in the urine and in the saliva were considerably reduced, but the cachexia and the atrophy of the lingual papillae remained unchanged. There are two possible explanations for the failure of vitamin B_{12} therapy in this patient. The synthesis of the thymonucleic acid from *thymidine may* have been disturbed directly by the chromium, or vitamin B_{12} may have been inactivated by the chromium as a result of its complex affinity.

BOOK REVIEWS

Psychosomatic Research. By Roy R. Grinker, M.D., Director of Institute for Psychosomatic Research and Training, Michael Reese Hospital, Chicago. Cloth. $3.50. Pp. 208. W. W. Norton & Company, Inc., 101 Fifth Ave., New York 3, 1953.

This book is based on two presidential addresses made by the author before the American Psychosomatic Society and the Chicago Psychoanalytic Society. Dr. Grinker is a well-known authority in the field on which he writes. The book consists of an exposition of his ideas and reflections and gives an over-all view of the field of psychosomatic medicine. In addition, it "attempts to develop a conceptual outline for new programs of psychosomatic research which may be valuable to others." It is justly called "A challenging appraisal of current psychosomatic concepts by one of the most active leaders in this field." The book delineates historical and current concepts, evaluates theoretical formulations and operational procedures, and discusses emperical observations. The author points out that particular psychosomatic expression is not constantly related to a specific emotional constellation. He says (page 61), "I believe that the central focus should not be either on the nature of the somatic functions, which is the subject matter of physiology, or on the psychological processes, which are independently studied by psychologists, psychiatrists and psychoanalysts, but on the forces contributing to psychosomatic unity, its developmental differentiation, and its unhealthy disintegration." There are two chapters on psychosomatic differentiation, which point out the "need for a multidisciplinary attack using many techniques of measurement applied to neonatal organisms and their human and physical environments through the first years of development." There is speculation as to why psychosomatic disturbances are on the increase in our Western culture. A discussion of "integration and field theory" is not too easy for the average person to comprehend. The book is more appropriate for the investigator in psychosomatic medicine than for the practicing clinician.

An Atlas of Skull Roentgenograms. By Bernard S. Epstein, M.D., Associate Radiologist, Jewish Hospital of Brooklyn, Brooklyn, New York, and Leo M. Davidoff, M.D., Neurosurgeon to Mount Sinai Hospital, New York City. Cloth. $15. Pp. 415, with 603 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1953.

This atlas of skull roentgenograms also contains excellent, concise introductions to the different groups of diseases manifest on the plain skull roentgenogram. One of the best features is the excellent coverage of the normal skull and its variations. The usual pitfalls that trap the uninformed are carefully explained and illustrated. There is some repetition, but this assures proper emphasis. The book is divided into 10 chapters covering the normal skull (including infant, childhood, and adult skulls), anomalies and malformations, trauma, infections, brain tumors, gliomas, primary sarcomas, lipomas of the brain, craniopharyngiomas and pituitary adenomas, miscellaneous tumors, tumors of the vault of the skull, and non-neoplastic diseases of the skull. The one notable exception is Caffey's disease, which is mentioned by the authors but is not illustrated. The selection of material for illustration is good, but the quality of reproduction could be improved. There are several typographic errors, which do not seriously detract from the book. One illustration is in a poor position for easy comparison. In short, this is an excellent book for neurosurgeons and roentgenologists, particularly those beginning work in either field, and is of interest to any who see plain films of the skull.

Psychiatric Treatment: Proceedings of the Association, December 14 and 15, 1951, New York, N. Y. Research Publications, Association for Research in Nervous and Mental Disease, volume XXXI. Editorial Committee: S. Bernard Wortis, M.D., Chairman, Morris Herman, M.D., and Clarence C. Hare, M.D. Cloth. $9. Pp. 451, with 49 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Ave., Baltimore 2, 1953.

During the past two decades, psychiatric treatment has covered a wide range of procedures, extending from a psychological and social milieu to pharmacological, electrical, and neurosurgical methods. In this symposium on psychiatric treatment, a concerted effort has been made by the contributors to evaluate the effectiveness of various therapeutic modalities. Dealing with individual and group therapeutic procedures and with electrophysiological, pharmacological, and neurosurgical methods, the symposium presents some of the advantages, weaknesses, and omissions in current psychiatric therapy. In summary, the papers indicate that the therapist should be cautious in advancing claims for the exclusive effectiveness of any single treatment or for any single factor influencing treatment in psychiatric practice, for apparently about one-third of patients fail to respond to treatment, one-third get well while under treatment, and one-third are more or less influenced by treatment. This volume should serve to stimulate scientifically critical studies in an important field.

Diabetic Manual for the Doctor and Patient. By Elliott P. Joslin, M.D., Sc.D., Medical Director, George F. Baker Clinic at New England Deaconess Hospital, Boston. Ninth edition. Cloth. $3. Pp. 315, with 55 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1953.

This new edition of an old, standard primer was written and revised by an acknowledged authority on education of the diabetic patient. As in the past, its style is delightfully simple and direct. Dr. Joslin has an intuitive feeling for answering the questions that all patients ask: the result is an absorbing text and a gold mine of information, presented for the most part in language even a child can understand. There are sections on the nature of diabetes and its incidence; the history of major discoveries, including insulin; instructions about food, urine testing, exercise, hygiene, and the use of insulin; diabetic acidosis and hypoglycemic reactions; infections and vascular complications; and heredity, marriage, pregnancy, and children. Occasional question and answer sections and brief, illustrative case reports, photographs, and diagrams amplify the didactic portions and add interest. The size is convenient, the type clear, and the workmanship of fine quality. This manual, one of the oldest, is universally used, chiefly because of the talent and experience of its author.

School Health Problems. By Laurence B. Chenoweth, M.D., Director, Department of Hygiene and Student Health Service, University of Cincinnati, Cincinnati, and Theodore K. Selkirk, M.D., Assistant Professor of Clinical Pediatrics, University of Cincinnati College of Medicine. Fourth edition. Cloth. $4. Pp. 446, with 122 illustrations. Appleton-Century-Crofts, Inc., 35 W. 32nd St., New York 1, 1953.

This college textbook, by authors who have written extensively in the field of preventive medicine and public health, first appeared in 1937. The fourth edition is evidence of its acceptability. The type and page size have been enlarged, and the general format makes for much easier reading, which is an advantage in a textbook designed for students of education and for teachers. Much of the material has been rewritten, reorganized, and supplemented. Sections concerning nutrition, malnutrition, and various factors that influence growth have been completely reorganized and new material added. New chapters on teachers' observations of the school child, dental health, the teaching of health, and the teacher's health are

---

The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

well handled and are given the prominence they deserve. References at the end of each chapter have been brought up-to-date, and those prior to 1940 have been retained only when they concern important source material. The footnote references are also complete.

This is a satisfactory book for teachers to use as a reference on the school health program and their role in it. It is also valuable for the undergraduate student of education to use, either as a textbook or as a supplement, in college courses dealing with school health activities.

Therapeutics in Internal Medicine. By eighty-four authorities. Edited by Franklin A. Kyser, M.D., F.A.C.P., *Assistant Professor of Medicine, Northwestern University Medical School, Chicago.* Contributors: M. David Allweiss, et al. Second edition. Cloth. $15. Pp. 830, with 3 illustrations. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1953.

The second edition of this book, presented in the classical arrangement of chapters according to related internal disorders, provides complete coverage of methods of treatment for nonsurgical diseases. The information is up-to-date and includes generally accepted methods along with some individual preferences of the contributors. There are 12 new sections and 17 new contributors. Like most other symposiums on treatment, the book does not include clinical descriptions of diseases. Only such physiological, etiological, and pathological information as may be required for an understanding of the principles of therapy is presented. The contributors are teachers, investigators, and administrators representing all branches of medicine except the surgical specialties. The preference given to trade names and the use of abbreviations by some authors is disappointing: ACTH is used as a generic name in place of corticotropin; D.T.P. appears as a generic synonym for diphtheria and tetanus toxoids combined with pertussis vaccine; BAL is used in place of dimercaprol; and D.D.T. is used instead of chlorophenothane. This tends to detract from the value of the book to students. The statement on page 601 that "Each tablet of phenylbutazone contains 250 mg." is difficult to reconcile with the currently available tablet sizes of 100 and 200 mg. For the most part the statements on dosage are accurate and detailed. An appendix of useful diets and tables of recommended daily allowances follows a final chapter on symptomatic treatment. A general index at the end appears carefully prepared. The printing and binding are excellent, and the double column format makes for easy reading. On the whole, this book on treatment deserves a prominent place among similar works, and it will appeal primarily to physicians who prefer one restricted to internal diseases.

Recurrent Dislocation of Shoulder. By James A. Dickson, M.D., Chief, Department of Orthopedic Surgery, Cleveland Clinic and Cleveland Clinic Hospital, Cleveland, Alfred W. Humphries, M.D., and Harry W. O'Dell, M.D., Chief, Department of Orthopedic Surgery, Akron Clinic, Akron. Cloth. $4.50. Pp. 158, with 78 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1953.

The number and variety of techniques that have been proposed during the past two decades in treatment of recurrent dislocation of the shoulder indicate the complexity of the problem and the controversial nature of various approaches to treatment. This small monograph begins with a review of the phylogenesis and ontogenesis, including a detailed study of anatomy and dynamics of the shoulder. Pathology is reviewed in detail, although the significance of the opening anteriorly of the shoulder joint into the subscapularis bursa, creating a normal anatomic weakness, apparently was not considered important by these authors. More than 50 principles or variations in operative techniques by as many different authors are listed, and the essentials of the commoner operations are described and illustrated in detail. Some confusion may result when the relatively inexperienced surgeon tries to determine, from the operations described, which of the various procedures would be most suitable for his patient. Treatment of recurrent posterior dislocations is also described briefly.

Epidemics in Colonial America. By John Duffy. Cloth. $4.50. Pp. 274, with illustrations. Louisiana State University Press, Baton Rouge, 1953.

In his research, the author has referred to the original colonial accounts of epidemics; the bibliography of these old records is one of the most valuable parts of the book. He ranks malaria, dysentery, and respiratory diseases as the most destructive, from a social and economic viewpoint, of the plagues that visited the colonists. He believes that smallpox, yellow fever, and diphtheria have been overrated as hindrances to colonial development. There is evidence, however, supporting a difference of opinion on the latter statement; for example, in the chapter on smallpox the author says, "A recent medical history estimates that the introduction of smallpox into Mexico in 1519 wiped out three and one-half million Indians. What was true of South and Central America held good for North America as well." In the same chapter he says, "An epidemic in Annapolis, Maryland, during this same winter of 1756-1757 delayed the convening of the assembly for five months." With regard to diphtheria the author quotes as follows: "In the parish of Hampton-Falls the disease raged most violently. Twenty families buried all of their children. Twenty-seven persons were lost out of five families; and more than one-sixth of the inhabitants of that place died within 13 months." As to yellow fever, the author says that it was one of the deadliest and most terrifying of all the infections that ravaged the American coastal cities. It is well known that during some of the yellow fever epidemics thousands of persons fled to the country to escape infection. The author traces chronologically the periodic waves of infection that passed through the colonies. He tries to show the number of deaths and the length of the outbreak and its effect on social and economic life. These historical accounts of epidemics and the frequent quotations from old reports make the book seem slightly dull, although its historical value is obvious. The author, who was born in England, became an American citizen in 1939 and 10 years later received a grant-in-aid from the American Philosophical Society for research in colonial epidemics.

History of the Second World War, United Kingdom Medical Series. Editor-in-Chief: *Sir Arthur S. McNalty, K.C.B., M.D., F.R.C.P.* The Army Medical Services. Administration. Volume I. By F. A. E. Crew, F.R.S. Cloth. 50s. Pp. 530, with illustrations. Her Majesty's Stationery Office, P. O. Box 569, London, S.E.1, 1953.

Almost eight years have elapsed since World War II ended, and the first of a series of volumes on the medical history of the war has just appeared. This is indicative of the amount of study of official records, their correlation, and the writing required to prepare an official history. This volume is one of two that will present the administrative phases of the British army medical department history. Beginning in 1933, the military members of the Army Council reviewed the position of the army with regard to its readiness for war. The medical services were unprepared, both in men and in medical equipment, to provide medical care for a large army. In this volume and the succeeding volume, readers will be able to review the conferences and planning and the tremendous tasks of the army medical services in undertaking medical care of the British armies in all theatres of war. In September, 1939, when the British expeditionary force was dispatched to France, the organization of the medical services for war differed little in principle from that in effect in 1918. When it was realized that many changes in the field organization had to be made, the director general of the medical services appointed the Hartgill Committee to examine the organization of the field services and to make suggestions for improvements in the light of the recent experience. This committee met in October, 1941, and two months later issued its report. The committee felt that four cardinal defects were apparent: (1) field medical units were insufficiently mobile, (2) field ambulances did not have adequate means of communication, (3) casualties were not distributed directly to the appropriate units but passed through channels that caused congestion at medical units in the forward areas, and (4) casualties were not afforded the benefits of modern surgery, that is, surgeons were located too far to the rear of divisions and corps. The result was that the Army Council decided to reorganize the medical services. The task of bringing the new scheme into effect proved long and difficult. Many of the details of how the reorganization was brought about are reviewed in this volume. It was written by F. A. E. Crew under the general direction of the editor-in-chief, Arthur S. MacNalty. The many others who assisted are given due credit.

The Alaska Vagabond, Doctor Skookum: Memories of an Adventurous Life. By John Michael Hewitt, M.D. Cloth. $3 Pp. 284. Exposition Press, Inc., 386 Fourth Ave., New York 16, 1953.

The author of this book, as a young man, was practicing medicine in a small Illinois town when gold was discovered in the Klondike. He and several others formed a company, assembled supplies of food, clothing, and mining utensils, and a small boat and went to Alaska to try their luck in the gold fields. The book is an account of his varied experiences over many years in Nome, Juneau, and other Alaskan settlements. Life was rugged in the wilderness. There were many more persons than there were dwellings available, although anyone in the saloon business seemed able to find some kind of shack in which to sell liquor. The author apparently did not find much gold in Alaska, but he seems to have enjoyed the life and to have done well practicing medicine under the hardships of frontier life. He tells of one hearty man who had a strangulated hernia but refused operation until the incarcerated intestine became gangrenous. The author saved the man's life by resecting a small part of the intestine and bringing the ends out through an opening in the abdominal wall. Much later he operated on this man again, with the aid of a Murphy button, and thus made an end-to-end anastomosis of the intestine. The author had considerable experience in Alaska with bone and pulmonary tuberculosis. He recognized even then the adverse effects of too much sunshine in pulmonary tuberculosis. Some of his operations were performed without much fear of infection, as he believed that interior Alaska was not "friendly toward germs." Later the author spent a number of years as an acting assistant Army surgeon in Alaska. He was retired in 1931 with the rank of major and has since lived in Los Angeles and Hollywood. His account of those adventurous years in the northland has an aura of camaraderie, good fellowship, and kindness to others less fortunate than himself. This interesting book was an ambitious undertaking although probably very enjoyable, for a writer who is now about 86 years old.

Einführung in die chemische Physiologie. Von Professor Dr. Emil Lehnartz, Direktor des physiologisch-chemischen Instituts der Universität Münster i.W. Tenth edition. Cloth. 39.60 marks. Pp. 549, with 119 illustrations. Springer-Verlag, Reichpietschufer 20, Berlin W. 35 (West-Berlin); Neuenheimer Landstrasse 24, Heidelberg; Göttingen, 1952.

This book was prepared as an introductory textbook in biochemistry. It is primarily for students of medicine, but enough reference material is included to make it of value to practicing physicians. The popularity of the book is attested by the fact that it is in its 10th edition. There has been a lapse of 10 years since the ninth edition was published, and consequently the current edition has been thoroughly revised and rewritten. Extensive use has been made of recent American, English, and Scandinavian literature; however, some chapters, for example, that on the inorganic constituents, contain no references after 1941, and the chapter on nucleic acids has only one reference more recent than 1943.

The material is divided into five main parts. The first discusses chemical constituents of the body, including carbohydrates, fats, steroids, proteins, nucleic acids, pyrrole pigments, and inorganic substances. The physical chemistry basic to proper understanding of biochemistry constitutes the second part. In the third part the physiologically active substances of the body are discussed, including vitamins, hormones, and enzymes. The fourth part deals with digestion, absorption, and the intermediary metabolism of carbohydrates, fats, proteins, nucleic acids, and pyrrole pigments. The fifth part includes chapters on the liver, blood and lymph, kidney and urine, and skin and milk.

The book is well written and compares favorably with American textbooks of similar size and scope. There are 119 excellent illustrations. Hormones and vitamins are extensively discussed. The section dealing with physiologically active substances of the body is excellent. The chapter on epinephrine, however, fails to give credit to J. J. Abel for his discovery and isolation of epinephrine as a benzoyl derivative. The chapter on the liver, which has no counterpart in American textbooks, discusses the role of the liver in metabolism of carbohydrates, fats, proteins, and nucleic acid. There is no discussion on the detoxication mechanisms in biochemistry; this would be a worth-while addition in future editions. In all, this is an excellent book and can be recommended as an introduction to biochemistry.

Pigment Cell Growth: Proceedings of the Third Conference on the Biology of Normal and Atypical Pigment Cell Growth. Edited by Myron Gordon. Cloth. $7. Pp. 365, with illustrations. Academic Press Inc., 125 E. 23rd St., New York 10, 1953.

Anyone interested in the subject of pigment, whether physician, biologist, chemist, or physicist, will find this an excellent source book, for it contains papers and discussions read at a meeting "designed to offer to each specialist an opportunity to explore paths of inquiry other than his own—to describe, perhaps explain and certainly to discuss the nature of the pigment cell and its contained melanin." The subject matter deals with the embryologic, genetic, endocrinological, pathological, physiological, and enzymatic problems of melanogenesis, as well as methods of study and treatment of normal and abnormal pigment cell growth in man. The medical research student will, of course, find the entire volume of value; the clinician will appreciate particularly the papers on acanthosis nigricans and those dealing with different phases of melanoma, all written by authorities in the field. An unusual feature is a report of a postconference session for the adoption of uniform nomenclature, during which recommendations were made for definitions of melanoblast, melanocyte, macrophage, and melanophore. The book is well bound, the paper is excellent, and the illustrations are informative and clearly defined. The indexed table of contents preceding each chapter is helpful in locating specific information quickly.

Liver Injury. Edited by F. W. Hoffbauer, M.D., Associate Professor, Department of Medicine, University of Minnesota Hospitals, Minneapolis. Transactions of eleventh conference, April 30 and May 1, 1952, New York, New York. Cloth. $4. Pp. 265, with 96 illustrations. Josiah Macy, Jr. Foundation, 16 W. 46th St., New York 36, 1953.

This book, as its predecessors, is a verbatim report of a conference of 30 leading investigators in the field of liver disease. As in all Macy Foundation conferences, the discussion is centered around five or six informal papers. In this volume the following subjects are presented: infective hepatitis, George F. Mirick; enzyme activity in human liver, John Waterlow; morphology of the liver, M. M. Hans Elias; the mechanism of biliary excretion in mammals, Elizabeth H. Bagley and Allen L. Grafflin; and hepatic histochemistry, Sten Lagerstedt. Much of the material presented at the conference represents work in progress and is still unpublished. The discussion is informal, extensive, and, because of the character of the participants, highly informative. The volume is well illustrated with tables, graphs, and plates, and reads easily. Pertinent references are included. This is an extremely interesting and stimulating volume, which should be read by all those interested in liver disease. Although much of the material is hypothetical and is only of theoretical interest at present, it should prove of interest to anyone with an inquiring mind.

When You Marry. By Evelyn Millis Duvall, Ph.D., and Reuben Hill, Ph.D. With chapters in collaboration with Sylvanus M. Duvall, Ph.D. Revised edition. Cloth. $3.75. Pp. 466, with illustrations. Association Press, 291 Broadway, New York 7, 1953.

This is a textbook written for personal study or for use in colleges and community centers to educate those contemplating marriage or already married. There is a wealth of information for the physician, lawyer, minister, and marriage counsellor. Such knowledge may prevent many broken homes and divorces.

Modern Concepts of Leprosy. By Harry L. Arnold, Jr., M.D., F.A.C.P., Department of Dermatology, Straub Clinic, Honolulu, Hawaii. Publication number 145, American Lecture Series, monograph in American Lectures in Dermatology. Edited by Arthur C. Curtis, M.D., Chairman, Department of Dermatology and Syphilology, University of Michigan, Ann Arbor. Cloth. $3.75. Pp. 105, with 33 illustrations. Charles C Thomas, 301-327 E. Lawrence Avenue, Springfield, Illinois; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1953.

This booklet was written by a dermatologist from the dermatological viewpoint. It presents the subject of leprosy to clinicians who desire more than brief information incorporated in textbooks of medicine but do not need extensive details. After discussion of the historical background and etiology of leprosy, the author considers the basic epidemiology of the disease, concluding that the "open" case is "potentially dangerous, especially for children." Nomenclature employed is that adopted at the Havana Congress on Leprosy (1948), namely, lepromatous and tuberculoid types and, in addition, an indeterminate group that has resisted classification. Diagnosis is based on clinical suspicion and differentiation from other cutaneous lesions and is supported by finding of the etiological agent in the lesion or evidence of nerve damage that can be attributed only to leprosy. Considerable emphasis is placed on the clinical features, histological characteristics, bacteriological and immunologic tests, and the clinical course, which distinguishes the lepromatous from the tuberculoid type of the disease.

Although prior to 1941 chaulmoogra oil and its ethyl esters were widely used in the treatment of leprosy, these proved of relatively little value. The advent of sulfone therapy was a marked advance, although all cases do not respond satisfactorily, either clinically or bacteriologically, and, at times, relapses have occurred in apparently cured patients. In the past, strict isolation of leprous patients in Scandinavia and Hawaii has resulted in a steady decline of the disease. Until more satisfactory epidemiological evidence is provided "it seems unwise to abandon restrictions on the movements and associations of bacteriologically positive cases."

Throughout the text it is evident that the author thoroughly appreciates the social implications of leprosy, but he fails to mention the therapeutic value of nourishing diet and congenial environment. Each of the nine chapters has a number of selected references, almost all of which are duplicated in a comprehensive bibliography, which precedes a subject index. The little volume has a pleasing format and is attractively bound.

Toxicity of Industrial Organic Solvents (Revised in Consultation with Toxicology Committee). By Ethel Browning. Medical Research Council, Industrial Health Research Board, report no. 80. Second edition. Cloth. £1 15s. Pp. 411. Her Majesty's Stationery Office, P. O. Box 569, London, S.E.1, 1953.

The first edition of this book was published in 1937 as a compendium of information about the effects on man and animals of various solvents used in industry. The revised edition summarizes more recent information on previously reviewed solvents and includes data on newer solvents that have come into use since the first edition was prepared. This edition reviews 126 different solvents grouped into 10 chapters under the following categories: hydrocarbons, chlorinated hydrocarbons, alcohols, ethers, esters, ketones, glycols and their derivatives, amino and coal tar bases, and nitrogen and miscellaneous compounds. Discussions of individual solvents cover properties, uses, acute and chronic toxicity to man and animals, lethal and narcotic doses and concentrations by various routes of administration and exposure, symptoms, and effects on the blood and internal organs. There are also data on estimation of the solvent in the atmosphere and in blood and tissues, manufacture, metabolism, differential diagnosis of poisoning, and effect of the solvent on the organism when combined with other solvents. An extensive bibliography complete up to 1948 is presented at the end of each chapter. The design of the book is attractive, and the paper, binding, and printing are of good quality.

Annual Review of Physiology. Volume 15. Editor: Victor E. Hall. Associate editors: Jefferson M. Crismon and Arthur C. Giese. Cloth. $6. Pp. 558. Annual Reviews, Inc., Stanford, Calif.; H. K. Lewis & Co., Ltd., 136 Gower St., London, W.C.1; Maruzen Company, Ltd., 6 Tori-Nichome, Nihonbashi, Tokyo, 1953.

This is another excellent volume of the series that began in 1939. A remarkable uniformity has been maintained, and the present volume even includes one of the authors represented in the first, namely, Frank C. Mann. There are no chapters on applied and industrial physiology, and the subject of anesthetics, included in the first volume, has since been surrendered to the pharmacologists. Similarly, the subject of physiological psychology has been omitted since the inauguration of an Annual Review of Psychology; it is replaced by one on higher functions of the nervous system. The scope of the volume is enlarged by a discussion of the physiology of vision; this chapter, together with one on thermal receptors, also represents the subject of special senses. Recent developments relating to cortisone and corticotropin add interest to a new chapter by Scharrer on the comparative physiology of invertebrate endocrines. An illustration of the rate at which scientific literature is accumulating is afforded by Krahl's collection (mentioned on page 32) of eight and one-half pages of bibliography on the metabolism of sea urchin eggs. The Annual Review of Physiology, with its decennial index volume, constitutes a priceless key to this literature.

Elsevier's Encyclopædia of Organic Chemistry. Founded by (the late) E. Josephy and F. Radt. Edited by F. Radt. Series III: Carboisocyclic Condensed Compounds. Volume 14, Supplement: Triterpenes. Co-edited by Dora Stern. Cloth. $40; $35 to series subscribers; $30 to set subscribers. Pp. 939S-1345S;50. Elsevier Press, Inc., 402 Lovett Blvd., Houston 6; 155 E. 82nd St., New York 28; 118 Spuistraat, Amsterdam C, Netherlands, 1952.

A relatively small amount of space was devoted to the triterpenes in volume 14 of the encyclopedia, but the recent increase in research on these compounds has necessitated a separate book to bring the data up-to-date. Thus, the literature in this supplement covers the period 1937 to 1946, and with regard to chemical structures the literature is reviewed up to 1952. The book covers derivatives of the pentacyclic terpenes of the α- and β-amyrin groups, lupane and heterolupane groups, the tetracyclic triterpenes, and triterpenes with an unknown number of atom rings.

Functional Disorders of the Foot: Diagnosis and Treatment. By Frank D. Dickson, M.D., F.A.C.S., Clinical Professor of Surgery, University of Kansas School of Medicine, Kansas City, and Rex L. Diveley, A.B., M.D., F.A.C.S., Assistant Professor Orthopedic Surgery, University of Kansas School of Medicine, Third edition. Cloth. $6.75. Pp. 345, with 205 illustrations. J. B. Lippincott Company, 227-231 S. 6th St., Philadelphia 5; Aldine House, 10-13 Bedford St., London, W.C.2; 2083 Guy St., Montreal, 1953.

The third edition of this book includes the important portions of previous editions and a section dealing with the rigid or spastic flat foot, which in many instances is secondary to a fusion or coalition between the os calcis and the astragalus, or the os calcis and the scaphoid bones of the foot. Thousands of patients have suffered throughout their lives because of this painful condition, and little was known about it until a careful study was made of prospective inductees in the Canadian army during World War II. This book is exceptionally practical and will be of value to every orthopedic surgeon and to physicians in general practice who are willing to take the time and the effort to try to help patients with painful feet.

The Anatomy of the Domestic Animals. By Septimus Sisson, S.B., V.S., D.V.Sc. Revised by James Daniels Grossman, G.Ph., D.V.M., Professor of Veterinary Anatomy in College of Veterinary Medicine, Ohio State University, Columbus. Fourth edition. Cloth. $15. Pp. 972, with 736 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, 1953.

The book is intended as a textbook for veterinary students and a reference for veterinarians. Equine, bovine, canine, and ovine organ systems are described in considerable detail, with emphasis on comparative anatomy. A short section is devoted to the anatomy of the chicken. The text has numerous illustrations, excellently reproduced and clearly labeled.

QUERIES AND MINOR NOTES

HUMIDITY IN THE HOME

To the Editor:—*Please discuss inexpensive methods of keeping the air in a house reasonably humid in winter (for prevention of the common cold). Does having plants and flowers in the home help? Why are plants removed from patients' rooms in hospitals?* M.D., *Pennsylvania.*

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—There is no inexpensive method for keeping the air in a house reasonably humid (30% relative humidity) during cold weather, nor is there any evidence that the maintenance of a high humidity will reduce the incidence of common colds. The amount of moisture that would have to be evaporated to obtain a relative humidity of 30% in a house heated to 70 F averages about 1 gal. per room per 24 hours when the outside temperature is 20 F. The use of double sashes or weather stripping at windows and doors will reduce this amount about one-half, and the use of double sashes also helps avoid condensation of moisture on windows under the above conditions. Obviously, the use of plants and flowers helps little in humidifying the air. In houses in which warm air heating is used, automatically controlled humidifiers integrated nto the heating system are generally the most satisfactory, but hey cost from $200 to $400. With steam or hot water heating, cabinet type humidifiers may be used, at a cost of from $100 to $500. The practice of removing plants and flowers from patients' rooms at night originated from the old, erroneous belief that they utilize oxygen that should be conserved for the patient. Today, plants or flowers are taken away to a cool place at night to preserve them. Unless a clean, cool place is available for storage, they keep better in the patient's room. Strong aromatic flowers should be removed to spare the patient constant olfactory stimulation.

Answer.—There is no simple, effective, and inexpensive method for providing added humidity in a house. Contrary to some recent reports, humidity levels during the heating season, except in houses with extremely cold or hot temperatures, are relatively unimportant. It is possibly true that a relative humidity of 70% in a house during the heating season is physiologically advantageous. Certainly, this is true of a 50% level; however, 25% saturation is not disastrous. The disadvantage of ill effects on household appurtenances offsets the physiological value of high humidities. In many houses a relative humidity higher than 35% may be detrimental to paint and plastering, and window panes may ice up to the point of unsightliness and the exclusion of sunshine. In steam-heated houses the slight cracking of release valves may supply abundant humidification. Devices sometimes installed in central hot air units often are short-lasting, flimsily constructed, and unsatisfactory. Water pans attached to radiators are effective in proportion to the amount of evaporation that occurs, but this procedure is not highly efficacious. In houses heated by stoves immediately within the living quarters, the time-honored kettle with boiling water provides satisfactory humidification. The best known, relatively inexpensive humidification device is the electrically powered small sprayer and distributor, of which there are many commercial types. These devices, which require only fairly frequent replenishment of water, are efficacious and generally durable. The simple practice of keeping open or repeatedly opening to a height of a few inches one or more windows increases humidity when the outside humidity is high. Plants and flowers in a household contribute to increased humidification only because evaporation continually takes place from plant surfaces and the top of the soil. A large-sized potted plant resting in a jar of water ordinarily will lead to evaporation of no more than about 1 gal. weekly. This is no great contribution to the humidification of the air of a house. The removal of plants and flowers every night from the room of a sick person is merely a habit carried over from the time when it was believed that flowers consumed oxygen and thus competed with the patient for the room's oxygen supply. Another reason for this practice is the recognition that the odors of flowers may become oppressive in a room that is likely to be closed up during the night. The justifiable reason for removing flowers from the sick room at night is to store them in a cool place to produce freshness for the following day.

SIGNS AND SYMPTOMS IN PULMONARY TUBERCULOSIS

To the Editor:—*The National Tuberculosis Association has designated degrees of pulmonary tuberculous disease as measured roentgenographically as follows: "Minimal—Slight lesions, without demonstrable cavitation, confined to a small area of one or both lungs, the total extent of which shall not exceed the equivalent of the volume of lung tissue which lies above the second chondrosternal junction and the spine of the fourth or body of the fifth thoracic vertebra on one side. Moderately advanced—One or both lungs involved, not to exceed in total extent, if slight dissemination, more than the volume of one lung, or if dense and confluent, more than one-third that amount, and total diameter of cavities, if present, not to exceed four cm. Far advanced—Any extension greater than moderately advanced" (Wampler, F. J.: Principles and Practice of Industrial Medicine, Baltimore, Williams & Wilkins Company, 1943, p. 379). I would like to know the different clinical signs and symptoms accompanying each of the three stages of the disease. This information will be used in connection with evaluation and rehabilitation of sick or disabled industrial workers.*

Jose S. Santillan, M.D., Manila, Philippine Islands.

Answer.—There is no specific set of clinical signs and symptoms for each stage of the disease. There has been a complete revision of the standards set forth by the American Trudeau Society in the 1950 edition of "Diagnostic Standards of the National Tuberculosis Association" (New York). The standards have not changed enough to make it impossible to answer the inquiry, but it must be emphasized that little can be proved "with requisite certainty" by physical findings. In determining severity of the disease, most weight must be given to roentgenographic evidence, which may be supported by the history, physical findings, and symptoms. Disillusionment with the clinical approach came with the improvement in and increase in use of roentgenograms, especially after World War I. Often, physical examination reveals little while at the same time roentgenograms show infiltrations of considerable extent, sometimes with cavities. On the other hand, many rales and signs suggestive of disease may be present and yet the roentgenogram shows little. It would not, however, be proper to allow these statements to stand without amplification, because the history and preliminary clinical examination are essential for the record, and they supplement the roentgenographic findings as nothing else can. It should be pointed out that careful physical examinations are costly and time consuming and should not be depended on in case finding surveys, nor should large roentgenograms be used for screening purposes. In industry, the physical examination is, of course, imperative and of much more value. With the foregoing qualifications in mind, the classical physical findings occurring in each of the three stages of disease will be discussed briefly.

Minimal.—Most minimal lesions produce no clinical signs or symptoms, especially during their early development. When the lesions become larger or more destructive in character,

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

humoral changes that are reflected in the blood cell counts and the erythrocyte sedimentation rate as well as an allergic skin reaction occur. When toxicity develops to a certain degree, several changes may occur. The reflex arc from lung to corresponding muscles causes muscle spasm (Pottenger's sign), which may be detected by careful palpation. This sign, although interesting, is generally unreliable in evaluating the amount and character of the underlying lesion, and few physicians are sufficiently experienced to use it. Percussion may or may not reveal changes in note, depending on the size of the lesion and its nearness to the surface. Breath sounds ranging from vesicular to bronchovesicular (rarely bronchial) may be heard but are unreliable as signs, since they may be altered in the absence of active disease. Auscultation may reveal a few crepitant and subcrepitant rales, but during much of the early development of the lesion, and even later, nothing at all may be heard. Whispered voice changes rarely occur with minimal lesions, since the changes that produce them are rarely present. The change in body temperature and pulse is even more erratic. There may be a 1 or 2 degree rise in temperature and a pulse rate as high as 90 beats per minute, but most of the time the early course is symptomless.

Moderately Advanced.—Moderately advanced lesions are more likely to give rise to detectable physical changes. All of the conditions mentioned above may occur, possibly over wider areas than with minimal lesions. Muscle spasm is more likely to be present. Scattered subapical consolidations may be detected on percussion, especially those near the surface, but deep infiltrates may be missed. The voice whisper may take on a more bronchial character as ulceration develops and as bronchi become dilated. Commonly, the body temperature rises 1 to 3 degrees, and the pulse rate may increase to 100 beats per minute, but there may be no change at all. Loss of appetite owing to toxicity may develop, with corresponding loss of weight. Pleurisy may or may not be present, depending on the nearness of the lesions to the surface of the lung.

Far Advanced.—In far advanced lesions, the whole gamut of changes described may occur. Commonly bronchial and sometimes amphoric breathing occurs, with occurrence of corresponding changes in breath sounds on whispered voice as cavities develop. Signs and symptoms accompanying earlier lesions are exaggerated in volume and more extensive in area. Again, they may be partially or entirely absent, even signs of deep cavities. In chronic disease, the signs and symptoms usually become abated, consolidations may be more evident, and the overlying muscles may show atrophy.

The signs and symptoms of the many variations and complications of the disease may be found in textbooks. Needless to say, the subject under examination should be charted as a surveyor would chart new land; such things as deviation of the trachea, apex beat of the heart, and scoliosis should be recorded. It should be emphasized again that signs and symptoms are sometimes deceiving and are only confirmatory when present. They may be misleading as to the exact degree of disease present, and they may be wholly absent. They must be elicited in the light of experience and always interpreted with wisdom and good judgment.

TREATMENT OF VENEREAL WARTS

To the Editor:—*Please suggest treatment for venereal warts; use of podophyllum resin in a 25% oil solution and various antibiotics has proved ineffective.* *M.D., Rhode Island.*

Answer.—If podophyllum resin was unsuccessful in the treatment of condyloma acuminata, electrodesiccation of the lesions following injection of a local anesthetic may be advisable. This should be followed by the use of a dusting powder, such as thymol iodide, and the patient should return at intervals not to exceed two weeks, so that young lesions may be destroyed before they act as a source of reinfection. Sitz baths of potassium permanganate, in a 1:15,000 dilution, may be advisable if many of the warts are removed at one sitting. The sexual partner, a possible source of reinfection, should also be examined and treated if found to have condyloma acuminata.

GENERALIZED PRURITUS

To the Editor:—*I have been treating a patient with rheumatoid arthritis with cortisone acetate since November, 1952. She is presently receiving a cortisone maintenance dose of 50 mg. three times weekly. About mid-January, generalized, severe pruritus developed, which has not responded to the usual applications. Administration of ephedrine by mouth and epinephrine intramuscularly failed to relieve the pruritus. The patient has been seen by an expert skin consultant, who feels that the pruritus may be caused by protein substances in the cortisone. I would appreciate your opinion and recommendations.* *M.D., New York.*

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—Generalized pruritus is not an expected complication of cortisone therapy. The pruritus in this case cannot possibly have occurred on the basis of allergy to protein products in cortisone acetate, because this product contains no protein. Diabetes mellitus of course can be aggravated by cortisone therapy, and generalized pruritus may come about indirectly in this way. Other internal causes of generalized pruritus must also be considered. These include, especially, liver or biliary tract disease, uremia, leukemias or lymphomas, and internal malignant disease. Intestinal parasites, focal infection, arteriosclerosis, and neurological or psychic causes for generalized pruritus have also been claimed. Among external causes of generalized pruritus without appreciable dermatitis, asteatosis is commonest and is the basis of so-called winter itch (Rothman, S., and Shapiro, A. L.: Itching [Pruritus] Chapter 31 in MacBryde, C. M.: Signs and Symptoms, ed. 2, Philadelphia, J. B. Lippincott Company, 1952, p. 713).

Answer.—Cortisone is a pure crystalline material, not a protein, and there are no "protein products" in either cortisone or its vehicles. Presumably, in this instance the cortisone is being given by injection. Cortisone for administration by this route is supplied as a suspension in sodium chloride solution, with a small, unspecified amount of a suspending agent and 1.5% benzyl alcohol. Occurrence of sensitivity to the suspending agents is possible but, insofar as this consultant is aware, has not been reported in the literature or substantiated in any unreported case. The reaction noted in this patient is most likely due to a factor or factors other than the cortisone or its vehicles. Additional consideration of physical, environmental, and emotional factors may be needed to clarify more precisely the basis for this patient's condition.

HYPERTENSION DURING TRANSURETHRAL RESECTION

To the Editor:—*What causes hypertension during transurethral resection of the prostate? In a recent case, alarming hypertension, followed by pulmonary edema, developed near the end of the procedure. Fortunately, recovery was effected by administration of digitalis and oxygen under pressure and the use of other emergency measures for several hours. Blood drawn after the complication occurred showed pronounced hemolysis, but a recheck to determine the blood group for cross matching did not indicate incompatibility. Distilled water was used as the irrigant during the operation.* *M.D., Wisconsin.*

Answer.—The occurrence of hypertension during transurethral resection of the prostate has two possible causes, hemolysis or extravasation into the paraprostatic tissue. Judging from the description, the hypertension in this case evidently was caused by hemolysis. The exact mechanism by which hypertension is produced in such cases is unknown. Oliguria does not always occur with hemolysis, but, when it does occur, it is usually fatal. Hemolysis usually can be prevented by the use of an isotonic sodium chloride solution for distending the bladder during resection.

SIX STILLBIRTHS

To the Editor:—*A woman, 40 years of age, who is Rh negative and who had a negative blood Wassermann test result is four months pregnant. Her husband is Rh positive. Her first child, born 16 years ago, is normal. Six other pregnancies, ranging at from 4 to 8 months of gestation, have resulted in abortions or stillbirths. 1. Whether the husband is homozygous or heterozygous Rh positive, is it possible for this woman to deliver a normal baby? 2. Is corticotropin (ACTH), cortisone, or any other substance of value in blocking antibody formation? 3. How often is an erythroblastotic infant born to Rh-positive parents?* *M.D., New York.*

Answer.—Not enough facts are given to permit a definitive answer. No mention is made of tests on the expectant mother's serum for Rh antibodies or of autopsy findings confirming the diagnosis of erythroblastosis fetalis as the cause of the stillbirths. If tests for Rh antibodies on the expectant mother's serum give negative results, some other explanation for the stillbirths should be sought. If all were due to erythroblastosis, the mother's serum would be expected to show Rh antibodies in very high titer. The correlation between Rh antibody titer and the frequency of stillbirths has been discussed by Wiener and co-workers (*Am. J. Obst. & Gynec.* **63**:6 [Jan.] 1952). Assuming that the stillbirths were due to erythroblastosis and that the mother's serum contains Rh antibodies in high titer, the questions may be answered as follows: 1. Only if the fetus is Rh negative is there any chance that the baby will be normal. This would be possible only if the husband is heterozygous. The blood types of the husband's parents should be determined, if possible, and if one is found Rh negative, this would prove the husband to be heterozygous. If the six stillborn fetuses were erythroblastotic presumably they were all Rh positive, and the chance of having six Rh-positive pregnancies in succession if the husband is heterozygous is only 1 in 32. Therefore, he probably is homozygous. Further light could be cast on the question by Rh subtyping, since persons of type Rh_1Rh_2 or type Rh_1Rh_1, for example, are presumably homozygous. If the husband is homozygous, every fetus would be expected to be Rh positive, and the occurrence of another stillbirth is highly probable. 2. The use of corticotropin or cortisone has not been shown of value in preventing the formation of Rh blocking antibodies. Certain investigators have claimed that the use of these hormones antenatally on highly sensitized Rh-negative pregnant women makes possible the birth of viable erythroblastotic infants, who can then be treated by exchange transfusion. The evidence offered in support of this contention is flimsy, and this problem requires further investigation. (For a discussion of the question, the following sources may be consulted: Queries and Minor Notes, *J. A. M. A.* **149**:1515 [Aug. 16] 1952; Queries and Minor Notes, ibid. **151**:697 [Feb. 21] 1953; Hunter, O. B., and Ross, J. B.: *South. M. J.* **45**:732 [Aug.] 1952.) 3. Erythroblastotic babies can be born to Rh-positive mothers. Such instances of erythroblastosis are generally caused by sensitization to the A or B agglutinogen, e. g., in cases in which the mother belongs to group O and the baby to group A or B. The resulting syndrome, which has been designated icterus precox, is generally much milder than erythroblastosis due to Rh sensitization, and spontaneous recovery is the rule. In fact, many of these cases are misdiagnosed as physiological icterus, although a few are severe and clinically indistinguishable from typical erythroblastosis caused by Rh sensitization. Occasionally, erythroblastosis occurs when an Rh-positive mother belongs to one Rh-Hr type and the baby to a different Rh-Hr type, owing to sensitization to one of the Rh-Hr factors other than Rh_0. In rare cases, isosensitization of the mother to unrelated blood factors, such as Kell and S, can cause erythroblastosis.

DETERMINATION OF SEX

To the Editor:—*I would appreciate information concerning the intrauterine determination of sex in the last trimester of pregnancy.* *Samuel E. Dakil, M.D., McAlester, Okla.*

Answer.—There is no dependable method of determining the sex of a child in utero at any stage of pregnancy.

REPAIR OF CYSTOCELE AND RECTOCELE

To the Editor:—*If a patient has a cystocele and a rectocele repaired and suspension of the uterus, should she have bilateral tubal ligation to prevent further pregnancy?*

Walter L. Cawood, M.D., Harlan, Ky.

Answer.—In general, it is desirable to defer such operations until after the childbearing age, but this is not always possible. A simple anterior colporrhaphy or a modified Fothergill procedure of the bladder advancement type for the cystocele is associated with little or no hazard to subsequent pregnancy, but amputation of the cervix is strongly contraindicated, because it is apt to cause miscarriage or, if the pregnancy goes to term, serious dystocia. A properly performed suspension, often combined with plication of the uterosacral ligaments, would not, of course, interfere with subsequent pregnancy. If the cystocele and rectocele are both large and associated with pronounced or complete prolapse of the uterus, many gynecologists will select vaginal hysterectomy combined with correction of the cystocele and rectocele. There are individual variations in both indications and preferred procedures, and it is obvious that in some patients religious considerations must be respected.

DIABETES INSIPIDUS

To the Editor:—*A businessman, aged 60, had a respiratory tract infection in January, and in February he contracted the "flu." After a week, he had urgency and frequency of urination and passed 4 to 5 liters of pale urine per 24 hours, which had a specific gravity of 1.000 to 1.005. In addition, he had a 7 lb. (3.2 kg.) weight loss, anorexia, and weakness. He has unilateral exophthalmos due to an old eye injury, slight blurring of the left disk, suppressed breath sounds over the lower left side of the chest posteriorly, and a blood pressure difference in the two arms, known to be present for many years, 120/80 in the left arm and 160/80 in the right arm. Roentgenograms show an asymmetrical sella turcica measuring 22 mm. in length and 14 mm. in depth. Roentgenograms of the chest show an extensive soft density involving the entire left lower lobe, which is characteristic of pneumonia. The visual fields are normal. Laboratory studies showed a normal blood cell count, erythrocyte sedimentation rate, blood sugar, cholesterol, and sodium levels, slightly lowered blood potassium and chloride levels, and a transient elevation of the nonprotein nitrogen level. The result of a Kahn test was negative, and an electrocardiogram was normal. Beta-hypophamine (Pitressin), 0.5 cc., caused nausea as did beta-hypophamine tannate, 0.5 cc. Does a pituitary adenoma cause diabetes insipidus, and is diabetes inspidus likely to appear for the first time at the age of 60? Should x-ray therapy be instituted?*

Harry Parks, M.D., Atlanta, Ga.

Answer.—This interesting case presents problems that need further investigation. The sella turcica is certainly large, and this may be due to a tumor. Diabetes inspidus can be caused by a pituitary adenoma. Diabetes inspidus may appear at any period from infancy to old age. The disease occurred for the first time at age 60 in one of this consultant's patients, who is now 84. Diabetes insipidus may occur following almost any sort of infection, including influenza and certain virus infections. There seems to be no reason why it could not follow virus pneumonia. X-ray therapy does not seem indicated at present. Further study should be made to determine whether a brain tumor is present. The ideal treatment of diabetes insipidus is the removal of the cause when possible. It would be desirable to have a neurosurgeon examine this patient to determine whether the patient has a pituitary tumor that may be removed. X-ray therapy to the pituitary and hypothalamic regions may be of value in relieving the symptoms of this disease, if the cause is a tumor that is radiosensitive and if the changes in the supraoptic hypophysial tract are not beyond repair. This patient has other complaints that deserve further study. The patient complained of urgency and frequency of urination. Diabetes insipidus usually does not cause urgency, although frequency is the rule. Since this patient has a pulmonary infection, it would be well to rule out a genitourinary tract infection or other genitourinary abnormality by means of pyelograms and prostatic examination. A transient elevation of the nonprotein nitrogen level is rare in diabetes insipidus. This finding may indicate genitourinary complications. Apparently the roentgenogram of the chest is characteristic of pneumonia in the left lower lobe; however, if this process does not clear properly, sarcoid, which also may cause diabetes insipidus, should be considered. Other details appear in the monograph on "Diabetes Insipidus" by Blotner (New York, Oxford University Press, 1951).

THYROID ADENOMA

To the Editor:—*A patient has a rounded mass in his neck about 1 in. in diameter in the region of the thyroid. This mass grew slowly over a three year period. The mass was removed intact, and, on pathological study, was diagnosed as a benign thyroid adenoma. In a case such as this one, should the complete lobe of the thyroid be removed, or should the mass alone be removed, since it had no appearance of malignancy?* *M.D., Kentucky.*

Answer.—The reason for removing solitary tumors of the thyroid is not so much that they may become malignant as that they may be malignant at the time of removal. For this reason, it is essential to remove the tumor in its entirety with a surrounding zone of normal thyroid tissue. Papillary carcinomas, which are the commonest carcinomas of the thyroid, infiltrate the surrounding tissue for some distance, and, as a general rule, a total lobectomy on the affected side is the best treatment for solitary nodules of the thyroid. If the nodules are small and are localized to the isthmus or an upper or lower pole, wide resection, with removal of a great deal of surrounding tissue, constitutes an adequate operation.

HYPOTENSION IN CARDIAC INFARCTION

To the Editor:—*Please discuss the treatment of the hypotensive or shock state in acute myocardial infarction in connection with the intravenous use of fluids and the use of pressor drugs.* *M.D., West Virginia.*

Answer.—Whether to treat actively the hypotensive or shock state associated with myocardial infarction is one of the most difficult decisions to make. In the usual shock state following surgery or injury, a myocardium that is normal or relatively so is being dealt with. Following myocardial infarction the physician is dealing with a myocardium that has been seriously injured and is confronted with a situation in which treatment of the shock state may place a burden on the myocardium with which it is unable to cope. The indication for intravenous transfusion is the occurrence of critical hypotension, which is a relative term. A fall in blood pressure from 200/120 to 100/60 may constitute a more critical situation than a fall from 130/80 to 80/50. The judgment of whether "critical hypotension" is present rests to some extent with the attending physician. The added presence of faintness, sweating, and pallid cyanosis is further indication of the shock state. An added burden is placed on the physician, owing to the fact that so many patients who appear to be in critical hypotension suddenly begin to recover spontaneously. Since the objective of treatment is to raise the blood pressure, the use of whole blood or plasma is the method of choice. Administration of 250 to 500 ml. may be necessary, but if a fair response is obtained with a lesser amount it is wise to interrupt the transfusion. The rate of administration is important. There is a tendency to keep the rate of flow at a very low level to avoid overloading the laboring myocardium; however, if the rate is too slow there will be no pressure rise and the purpose is defeated. A flow of at least 2 ml. per minute seems necessary, and 4.5 ml. per minute is not rare. It must be remembered that when transfusion is decided on, the situation is as bad as it can get, and hazards are accepted that usually would not be considered. Arterial transfusion in this situation has been studied. This maneuver requires special equipment and expert technique. The transfusion must be done under a pressure that exceeds arterial pressure by no more than 10 mm. Hg, and the transfusion pressure must be constantly adjusted to the arterial pressure. In the experimental animal made hypotensive by bleeding, intra-arterial transfusion shows the infused fluid to permeate immediately the renal, coronary, and cerebral vessels. Theoretically this would constitute a great advantage, but in actual practice in myocardial infarction the mortality with its use is exceedingly high. Of course, persons with myocardial infarction who are subjected to this procedure are all desperately ill. The results following intravenous transfusion are not good, but persons in whom the procedure is used are also desperately ill. The use of pressor drugs is not encouraged. They are used, as a rule, only as a last resort and have been found generally ineffective. At best, the result is transient.

PENICILLIN FOR PHARYNGITIS

To the Editor:—*What is the penicillin serum concentration considered sufficient to "cure" a streptococcic pharyngitis?* *M.D., Massachusetts.*

Answer.—Bicillin (dibenzylethylenediamine dipencillin G) and Eskacillin (crystalline potassium penicillin G with added buffer) are both highly effective in the treatment of pharyngitis due to the beta hemolytic Streptococcus. The essential difference between these two agents lies in their speed of absorption and excretion. Bicillin is absorbed and excreted slowly and produces, therefore, prolonged but relatively low, although effective, blood levels. Eskacillin, on the other hand, yields higher levels that are sustained for only a short period. The concentration of penicillin in the serum considered sufficient to "cure" a streptococcic pharyngitis must be evaluated in terms of the susceptibility of these organisms in the test tube. Almost all strains of the beta hemolytic Streptococcus are inhibited by 0.015 to 0.03 unit of penicillin per milliliter. Concentrations in the blood of from 0.1 to 0.15 unit should be adequate. Such concentrations can easily be produced by the administration of crystalline penicillin G by mouth. There is good evidence that therapeutic blood levels need not be present constantly to cure streptococcic pharyngitis. The administration of 150,000 units of buffered crystalline penicillin G orally three times a day or 250,000 units by mouth every 12 hours will cure streptococcic pharyngitis rapidly and, if given for seven days, will completely prevent the development of suppurative complications (Weinstein, L., and Perrin, T. S.: *J. Pediat.* 37:844, 1950. Weinstein, L., and Daikos, G.: *Am. Pract. & Digest Treat.* 2:60, 1951).

PURPURA AND PREGNANCY

To the Editor:—*A 29-year-old white married woman had thrombocytopenic purpura at age 22, which lasted for two years and was finally cured by splenectomy at age 24. There has been no purpura since the splenectomy. The patient is one month pregnant. What are the chances of purpura developing during pregnancy or puerperium, and would its effect likely be of a serious nature? What are the chances of purpura developing in the baby? What special precautions should be taken.* *M.D., Canada.*

Answer.—Since the patient has been free from purpura for five years, the chance of a relapse occurring during pregnancy is small. Pregnancy does not appear to be a cause of reappearance of thrombocytopenic purpura following splenectomy. Under these circumstances, one would not expect purpura to develop in the child. Purpura in pregnancy would be serious (over 50% mortality when splenectomy is not performed). There is a possibility of the occurrence of purpura in some babies if the mothers have thrombocytopenic purpura. In the absence of a known case of thrombocytopenic purpura, little can be done to prevent its reappearance. In nonpregnant women corticotropin (ACTH) or cortisone has been used with good results, and administration of calcium lactate and vitamin E (200 mg. daily) has been followed by a remission in some patients.

ELEVATED BLOOD UREA CONTENT

To the Editor:—*Of what significance is the urea content of the blood in the diagnosis of leptospirosis?*

Lynn W. Whelchel, M.D., Miami, Fla.

Answer.—An elevated urea content of the blood in a patient with clinical manifestations of hepatitis, meningitis, or an obscure febrile disorder should suggest the possibility of leptospiral infection, especially if accompanied by leukocytosis and conjunctivitis. It is a nonspecific condition, however, and the diagnosis can be established only by bacteriological or serologic evidence. Occasionally, a patient may have manifestations predominantly of renal involvement and a clinical condition similar to that of acute glomerulonephritis. Elevation of the blood urea concentration may occur as the result of either the nephritis, which is a part of the disease, or extrarenal factors. The renal lesion in fatal cases usually consists of considerable damage to the proximal tubules, with varying degrees of damage to the glomeruli. This may be manifested clinically by albuminuria, hematuria, cylindruria as well as azotemia, with or without edema and usually without hypertension. There may be oliguria, which in severe cases may progress to complete anuria. Extrarenal urea retention may occur as the result of shock in overwhelming infections, marked dehydration accompanying fever or vomiting, or gastrointestinal hemorrhage, which rarely is a complication of this disease. The blood urea concentration is also of prognostic value, most reported deaths attributable to this disease having occurred in patients showing severe renal impairment. A greatly elevated or rising blood urea concentration, with severe or progressing oliguria or anuria, connotes a grave prognostic sign and emphasizes the necessity of appropriate and adequate therapy directed toward prevention of complete renal shutdown and death.

INDICATIONS FOR MASTOIDECTOMY

To the Editor:—*Could you state briefly the present day indications for mastoidectomy?* *M.D., Nebraska.*

Answer.—Modern antibiotic therapy and chemotherapy, in adequate dosage, have proved extraordinarily effective in acute suppurative otitis media. As a result, only rarely does persistent acute infection in the middle ear and mastoid require simple mastoidectomy. Two types of lesions may require surgery: (1) those in which inadequate or no previous antibiotic therapy or chemotherapy has been used and in which develop a complication of acute mastoiditis, such as subperiosteal abscess, sigmoid sinus thrombophlebitis, meningitis, suppurative labyrinthitis, brain abscess, or facial nerve paralysis; (2) those due to infection with an organism that is resistant to the available antibiotics and in which the discharge from the ear persists, despite adequate chemotherapy and antibiotic therapy, with the development of the classical signs and symptoms of coalescent mastoiditis. These signs and symptoms are persistent discharge of more than three or four weeks in acute otitis media, sagging of the posterosuperior meatal wall, periosteal thickening and tenderness over the mastoid process, pain, especially nocturnal, low grade fever, or any of the abovementioned complications due to extension of the infection to an adjacent structure. Roentgenograms are also helpful in determining whether a mastoiditis requiring surgical treatment is present. The radical mastoid operation is indicated in cases of chronic suppurative otitis media of the bone invading type. With few exceptions, these are cases of cholesteatoma formation in the attic or antrum, with a marginal type of tympanic membrane perforation from which the typical flakes of cholesteatoma may be obtained by attic irrigation. In cases in which the cholesteatoma cavity is shallow and easily accessible, it can be rendered dry, odorless, and inactive by occasional attic irrigation. In cases in which the cavity is deep and less accessible, the radical or modified radical mastoidectomy is indicated to exteriorize the cholesteatoma cavity to arrest the continued bone erosion and eliminate the danger of extension to an adjacent structure, with one of the complications mentioned.

TUBERCULOSIS OF ENDOMETRIUM

To the Editor:—*A 24-year-old woman, with one normal child 3 years old, gave birth one month prematurely to a second child. One month following delivery pneumonia developed in the infant, and it died. Postmortem examination revealed miliary tuberculosis. Subsequently the mother had a dilatation and curettage, and the scrapings showed tuberculosis of the endometrium and cervix. She has been receiving a course of streptomycin and p-aminosalicylic acid. The erythrocyte sedimentation rate has dropped to normal values. What further course of action would you pursue?*

M.D., Idaho.

Answer.—The treatment is correct and should be continued, provided the proper dosage is given (1 gm. of streptomycin twice a week and 12 gm. of *p*-aminosalicylic acid a day in two to four doses). It may be wise to alternate streptomycin with dihydrostreptomycin to prevent vestibular damage that may come from long administration of streptomycin or auditory damage that may occur with use of dihydrostreptomycin. Recently the two have been combined so that the toxic effects of each may be minimized. Such a combination is commercially available. The length of time of treatment will vary, but under the circumstances it would be well to continue it for 10 to 12 months. At the end of that time, another dilatation and curettage should be performed, and a careful pathological examination and animal inoculation should be done to see if a cure has been effected. If any doubt exists, treatment with isoniazid may be started, alone or preferably in combination with the other two drugs.

LEFT-HANDEDNESS

To the Editor:—*1. Does left-handedness cause inhibitions that might delay normal development, for example, development in speech? 2. Can it cause later adjustment problems if improperly handled? 3. Is it preferable to allow the tendency to use the left hand to continue or to take reasonable steps early to discourage this tendency? 4. What adjustment should be anticipated and aided if use of the left hand is allowed to continue?*

William E. Russell, M.D., Richland, Wash.

Answer.—1. Left-handedness does not necessarily cause inhibitions that may delay normal development. It may do so when it is not well established so that there is confusion. 2. Later adjustment problems may be caused if left-handedness is improperly handled. 3. It is preferable to allow the use of the left hand if this is the distinctly preferred hand. A single possible exception to this may be the encouragement of the use of the right hand in eating so as to avoid later social embarrassment. This should not be persisted in, however, if it proves difficult. 4. If, as school age is approached, there seems to be confusion in learning to read, with evidence of a tendency to reverse visual images, the special methods for teaching of reading that have been developed for such children should be utilized. The school should be in the position to handle this problem if it arises.

ANTICOAGULANTS FOLLOWING CEREBRAL HEMORRHAGE

To the Editor:—*Would use of any of the anticoagulants be indicated in treatment of a 73-year-old man with severe arteriosclerosis who had a cerebral hemorrhage? The left arm is paralyzed and the speech center is partially affected. The blood pressure was 200/100 shortly after the stroke; however, it now varies between 140 and 150 mm. Hg systolic and between 86 and 90 mm. Hg diastolic.*

M.D., Kansas.

Answer.—There is insufficient evidence in favor of the use of anticoagulants in such patients, and there is a possibility that damage may be done. Until convincing proof is available, it would appear inadvisable to use them.

REMOVAL OF CERUMEN

To the Editor:—*Often I see patients who have hard, impacted cerumen in their ears, which precludes examination of the tympani membrane. Sometimes, attempts to remove the cerumen with a curette after instilling a few drops of hydrogen peroxide and washing the ears with a syringe fails. Frequent use of a glycerin solution over a period of days does not always succeed in loosening it enough so that it can be removed successfully without damaging the external auditory canal. What is the best method of removal? What is the composition of cerumen? Is there any reason why trypsin, Alevaire (an aqueous solution containing 5% glycerin, 2% sodium bicarbonate, and 0.125% of an alkylaryl polyether alcohol), streptokinase, or streptodornase should not be instilled into the ear to reduce the viscosity of cerumen?* R. T. Hood Jr., M.D., Craig, Ala.

Answer.—Cerumen is a natural secretion of the ceruminous glands, which together with sebaceous glands and hair follicles are located in the outer membranocartilaginous portion of the external auditory canal. Some persons tend to secrete excessive amounts of cerumen, just as some persons tend to perspire freely. The standard methods for removing impacted cerumen include syringing with water alone, syringing after preliminary softening of the cerumen by frequent instillation of sodium bicarbonate in glycerin or hydrogen peroxide, and the use of an ear spoon or curette. Generally, cerumen can be removed successfully when gentleness, patience, and a correct technique are employed. Fresh cerumen is composed of variable amounts of water, fats, free fatty acid, cholesterol, and lecithin. While there are no known contraindications to the instillation of trypsin, Alevaire, streptokinase, or streptodornase into the external auditory canal, it is doubtful whether they are suitable for digesting or reducing the viscosity of cerumen.

PREMATURE INFANT

To the Editor:—*What would be the results of giving a 3 lb. (1,360 gm.) premature infant 3¾ grains (0.24 gm.) of caffeine and sodium benzoate and 1 cc. of nikethamide (Coramine) intramuscularly at the same time? Is this overdosage? What would be the correct dose of each for an infant of this weight?*

Edward S. King, M.D., Shelby, N. C.

Answer.—The doses of caffeine sodium benzoate and nikethamide suggested for administration to a premature infant of the size mentioned are unquestionably excessive. The results would be an increase in the respiratory and cardiac rates. For certain conditions in premature babies in which cardiac or respiratory stimulation is desirable, authorities have suggested use of nikethamide in a dose of 0.5 cc. and caffeine sodium benzoate in a dose of ⅙ to ½ grain (10 to 30 mg.). The use of these drugs in premature babies has, according to many physicians, doubtful value.

IRRITABLE BOWEL SYNDROME

To the Editor:—*A patient has spastic colitis in the sigmoid and descending colon, with irritability and frequent contractions. A barium enema revealed normal filling, and no ulcer or filling defects, diverticula, or other organic pathological conditions were noted. The ascending and transverse colon are normal in every respect. Roentgenograms of the upper gastrointestinal tract reveal no evidence of an organic lesion. For six months, gripping low abdominal pains associated with gas pockets in the large bowel and constipation have been experienced. Sensitivity to certain foods is present, and attempts to eliminate the offending foods have been made. What is the current treatment for spastic colitis? Antispasmodics and petrolatum have been used.*

M.D., Florida.

Answer.—The term "spastic colitis" is not well chosen, because in persons with this condition there is no intestinal inflammation to account for the symptoms. The condition commonly referred to by this term is better described as the "irritable bowel syndrome," but even this term is not entirely descriptive of the condition. It points, however, to the fact that the condition is in the nature of a part of a general bodily disturbance in which the bowel may play a role. This role may be major, and, when the symptoms are directed largely to the abdomen and intestinal dysfunction occurs, use of one of the antispasmodics is helpful. The main need is for adoption of better habits of eating and living. It is especially important that such patients get adequate rest and restful relaxation and that they eat a nutritious diet, in which a good breakfast and adequate fluid intake are of the greatest importance. At times, lubricants taken orally or as rectal instillations are helpful, but it is best to use them for only a short time to help regulate bowel function.

HEPATITIS COMPLICATING PREGNANCY

To the Editor:—*A 35-year-old para 2 whose first child was delivered normally had jaundice at the time her second child was delivered (stillborn), in 1949. Symptoms, such as malaise and epigastric distress, began five days before the onset of labor. At the start of labor, the patient was jaundiced. Delivery proceeded uneventfully. Subsequently the patient became critically ill. The jaundice deepened, and the patient became extremely lethargic and was unable to retain food. The icteric index rose to 56, the cephalin flocculation was 4+, and the serum alkaline phosphatase level was 17 Bodansky units. With the usual treatment measures, including administration of glucose intravenously and vitamins B and K and rest, the patient recovered. For the last three years she has been well, except for moderate "gas distress." Results of a recent physical examination were entirely normal. The blood cell count was normal. The total blood protein level is now 6.76 gm. per 100 cc. (albumin 5.55 gm. and globulin 1.21 gm). The cephalin flocculation is 1+. The patient is anxious to have more children. Would pregnancy be dangerous?* Henry Krochmal, M.D., Meriden, Conn.

Answer.—The history suggests infectious hepatitis complicating pregnancy at term, resulting in fetal death in utero, subsequently clearing on supportive therapy, and, at present, without demonstrable residuals. There is no reason, on the basis of these facts, to suppose that another pregnancy would be dangerous for this woman. Emphasis should be placed on the patient's receiving optimal nutritional levels of protein, minerals, and vitamins, and she should be carefully followed during future pregnancies. Other than these measures, there seems to be no need for special precautions.

BLOOD TRANSFUSION

To the Editor:—*What laboratory procedures are necessary to determine the need for blood transfusion and the amount of blood required? Is there any objection to administration of the blood of a person from one race to a person from another? What objection is there to the taking of blood from a donor who has partaken of a fatty meal or from persons having high blood pressure?* M.D., New York.

Answer.—Which laboratory tests are required for determining the need for blood transfusion depends on the condition of the patient and the possible reason for the transfusion. In patients in profound shock or with profound blood loss, transfusion may be necessary before laboratory studies can be done. For certain patients undergoing surgical procedures only erythrocyte and hemoglobin estimations may be needed, while for patients with blood dyscrasias elaborate studies usually are required. There is no major objection to administering blood from persons of one race to those of another, but the possibility of introducing incompatible antigens must be kept in mind; for example, D^u variants may be encountered more frequently in one race than in another, and precautions to detect such variants must be taken in blood typing procedures. It is believed that use of blood from fasting donors reduces the incidence of allergic reactions. Also, the presence of chyle in plasma may obscure cloudiness due to bacterial contamination. If a hypertensive person should have a cardiovascular accident following blood donation, the accident may be charged unjustifiably to the bleeding procedure. Therefore, it is wise to bleed persons with hypertension only as a therapeutic measure.

SCANTY MENSTRUATION AND HOT FLASHES AT 27

To the Editor:—*A patient, 27 years old, complains of having had scanty menstruation for eight months, hot flashes for six months, and nervousness and irritability for five months. The flow has been brighter in color for the last six months. The patient has had no pregnancies and menstruates regularly for 4 days every 28 days. She is 5 ft. (152.4 cm.) tall, weighs 130 lb. (59 kg.), and has fair skin and blond hair. Her blood pressure is 120/80 mm. Hg, her temperature 98.8 F, and her pulse rate 80 beats per minute. She has a congenital cataract. Results of pelvic examination were essentially normal except for the presence of a small cyst on the right ovary. The grandmother entered the menopause at age 30, the mother at age 36, and an aunt at age 32. I would appreciate information regarding treatment. This patient has had three injections of estrogens, with little improvement.* *Loren A. Dunton, M.D., DeLand, Fla.*

Answer.—Management of this case should be started by a complete medical evaluation, and efforts should be made to improve the patient's general health. The height and weight figures suggest that weight reduction is urgently indicated. This should be accomplished by a high protein, high vitamin, low calorie diet. If anemia is present it should be corrected by appropriate iron therapy. The basal metabolic rate should be determined, and small doses of thyroid given if it is normal or below. The patient's habits and social history should be explored to determine possible sources of irritability, nervousness, or conflict, and such factors should be corrected as far as possible. General healthful measures should be outlined, with particular reference to adequate sleep, diversion from routine duties and responsibilities, and appropriate daily outdoor exercise. Small doses of phenobarbital or mild sedatives combined with amphetamine may be a useful addition to the above regimen. Despite the family history of "premature menopause," the occurrence of the climacteric at the age of 27 is so extremely unusual that it should not be considered in this case so long as regular menstruation occurs. Accordingly, sex hormone therapy is not indicated. It should be emphasized that whenever use of estrogens is indicated, inexpensive active preparations for oral use of any desired potency are available; injections should be used only when oral preparations are not applicable. The ovarian cyst should, of course, be examined regularly but need be removed only if it causes pain, if it persists at a diameter of greater than 5 cm., or if a similar cyst appears on the opposite side.

COLOR OF OPERATING ROOM WALLS

To the Editor:—*What is the most suitable wall coloring for surgical theaters in hospitals?*

Niksa Mikajlovic, M.D., Jugoslavia.

Answer.—The color most used in operating rooms in the United States is a soft shade of gray-green. This choice is based on the following principles: the wall color should be restful to the eye, it should have reasonably good light reflective characteristics without glare, and, while being relatively neutral in effect, it should contain a satisfying amount of color complementary to the vivid coloring of the area of visual concentration, i. e., the body tissues.

FREQUENT DESIRE TO URINATE

To the Editor:—*A 72-year-old patient has advanced paralysis agitans (Parkinson's disease). Her chief complaint is a frequent desire to urinate, especially at night. Occasionally at such times, attempts to urinate result only in excretion of a drop or two of urine and sometimes not even that much. The use of trihexyphenidyl (Artane) hydrochloride, sedatives, or hyoscyamus does not relieve this symptom. Is there anything else I can give her?*

M.D., New York.

Answer.—Urinary disturbances occur rarely in paralysis agitans; they are not characteristically associated with the disease. It would be advisable, therefore, to look for other causes of the urinary urgency and frequency, e. g., urinary calculi. If there is no local pathological condition in the urinary tract, the patient described may have one of the rare parkinsonian urinary complaints. Since trihexyphenidyl, sedatives, and hyoscyamus do not relieve the symptom, use of belladonna alkaloids may be tried. A combination that seems to work fairly well is trihexyphenidyl, the belladonna alkaloids, and an antihistaminic drug, such as diphenhydramine (Benadryl) or Thephorin (2-methyl-9-phenyl-2,3,4,9-tetrahydro-1-pyridindene). The use of a muscle relaxant, such as mephenesin, may also be tried.

PERNICIOUS ANEMIA

To the Editor:—*When a satisfactory blood level has been obtained in a patient with pernicious anemia, what is the minimum amount of liver extract or liver extract and vitamin B_{12} that should be given each month to maintain this condition in a case in which it is not convenient to perform laboratory checks on the patient's condition?*

M.D., Illinois.

Answer.—The quantity of liver substance necessary for maintenance of normal blood levels varies among patients with pernicious anemia. Nevertheless, an ample quantity of antipernicious anemia substance for a patient without complications would be supplied by weekly injection of liver extract containing 20 to 30 mcg. of vitamin B_{12}. There is evidence to suggest that the liver extract may be satisfactorily replaced by a solution of vitamin B_{12}. If an erythrocyte count could be obtained even at six month or yearly intervals, subsequent dosage intervals might be predicted on the basis of the level present. Theoretically, four times the weekly requirement may be given in one injection each month; however, some patients do not tolerate well the larger single injection, and there is some question as to whether the single larger quantity of solution of vitamin B_{12} would be as effective as the same amount divided into smaller doses and given oftener.

CONTRACTION IN SCARS

To the Editor:—*Please advise what to do to prevent scar contractures. A flexion contracture of the third and fourth fingers following a burn is developing in a 20-year-old patient.* *C. L. Concklin, M.D., Corpus Christi, Texas.*

Answer.—The only satisfactory treatment of scar contracture is complete excision of the scar and covering of the resulting raw surface with a whole thickness graft of skin from another part. The healing of a raw surface always results in scar tissue formation. This gradually contracts, and particularly so if the original burn or injury involved a flexor surface. The resulting contracture tends to become more marked with growth of the hand, because scar tissue does not grow as normal tissues do. Attempts to overcome flexion contractures by splinting and stretching are futile. The fact that tissue has been lost must be faced, and the only satisfactory treatment is complete replacement of the destroyed tissue.

THE AUSCULTATORY GAP

To the Editor:—*A white woman, aged 84, has had a systolic blood pressure of from 190 to 240 mm. Hg for 10 years; the diastolic pressure remains at 75 to 89 mm. Hg. Several physicians have examined her, and all are puzzled by the fact that, as the mercury in sphygmomanometer drops the sound disappears at 170 mm., and there is silence until it reaches 130 mm., when it reappears; it finally disappears, as stated, at from 75 to 89 mm. What is the significance of this phenomenon? This is the only such patient I have seen in 25 years.* *Dan W. Scott, M.D., Houston, Texas.*

Answer.—This phenomenon is the so-called auscultatory gap. The sound disappears after the initial systolic sound is heard, only to reappear 20 to 40 mm. Hg lower. It is not a rare occurrence in hypertension, focal arteriosclerosis, and aortic stenosis. Its mechanism is not known, and it has no known prognostic value. Its chief importance seems to be that it may cause an error in the systolic reading if the upper reading is missed owing to the gap.

DIFFERENTIAL DIAGNOSIS OF POLIOMYELITIS

Clifford G. Grulee Jr., M.D., New Orleans

It is startling that the diagnosis of a disease on which so much professional effort and interest has been focused is suspected far more frequently than it is definitely made. A final diagnosis, even in the presence of typical clinical features, must depend on demonstration of the virus, either by animal inoculation or tissue culture techniques, as well as on changes in antibody titers between the acute and convalescent phases. Nevertheless, the diagnosis of poliomyelitis can be presumed with some confidence on purely clinical grounds as can the diagnosis of other viral diseases, such as measles or mumps, which is also most difficult to substantiate. In epidemics the suggestive spinal fluid findings and the typical spotty lower motor neuron type of paralysis may often justify an unequivocal clinical diagnosis. At times of high poliomyelitis incidence, however, the diagnosis of any vague febrile illness offers difficulties comparable to those of uncomplicated chickenpox if there is no skin rash. When it is realized that many abortive and nonparalytic cases occur, it should also be realized that persons with these mild forms of the disease may be just as important in spreading poliomyelitis as the less fortunate patients with obvious paralytic involvement.

In the following discussion, differential diagnosis will be considered under four headings, namely, cerebrospinal fluid changes, diseases exclusive of poliomyelitis that are associated with paralysis, virus and other infections of the central nervous system, and simulated illness caused by fear.

CLINICAL FEATURES

The diagnosis of paralytic poliomyelitis is usually suspected before a physician is called, and typical clinical features often allow quick confirmation. Paralysis is flaccid, with patchy asymmetric involvement of muscle groups relatable to segmental spinal innervation, and the deep and superficial reflexes are depressed or absent. Nuchal rigidity as well as signs such as resistance to straight-leg raising and the tripod sign when the patient attempts to sit erect are present in variable degree. Painful spasm in uninvolved muscle groups may be extremely disturbing. Occasionally, when paralysis is extensive, segmental spinal innervation is not recognizable. In this circumstance, associated clinical findings, such as intact cutaneous sensibilities, persistence of some muscle function in the fingers and toes, absence of increased intracranial pressure, and the general characteristics of the clinical illness, furnish a basis for the best possible judgment.

CEREBROSPINAL FLUID CHANGES

While routine lumbar puncture is certainly not always necessary or even desirable in an otherwise typical case, any real doubt as to diagnosis justifies its performance. If the disease is poliomyelitis, cerebrospinal fluid changes can usually be expected; but during the first two or three days of the clinical course, whether paralysis develops subsequently or not, examination may reveal normal findings in a small percentage of patients. After clinical diagnosis is reasonably established, little or no prognostic or therapeutic advantage is realized by study of the cerebrospinal fluid, and an acutely ill patient may be exposed to unnecessary manipulation, discomfort, and emotional distress. Typically, blood cell counts vary from 10 to 200 per cubic millimeter but may go as high as 1,000 to 1,200 per cubic millimeter.[1] Protein values are highest by the sixth week [2] and are most elevated in patients with paralysis.[3] Important in differentiating poliomyelitis from bacterial meningitis are the facts that the sugar in the spinal fluid remains normal and that intraspinal pressures are not so greatly increased. Probably lumbar puncture is most helpful in diagnosing nonparalytic forms of the disease. In order to institute appropriate supportive regimens of rest and medical supervision and to formulate an accurate epidemiological picture, detection of such cases has become increasingly important.

CONDITIONS CAUSING CONFUSION

What are some of the conditions with which paralytic poliomyelitis may be confused? As Wilson [4] points out, the first decision is whether true paralysis or merely

---

[4] Wilson, J. L.: Acute Anterior Poliomyelitis, in The Child in Health and Disease, ed. 2, Baltimore, Williams & Wilkins Company, 1952.

pseudoparalysis is present. Particularly in children, a reason for splinting a painful part may be difficult to discover; osteomyelitis, trauma, scurvy, and syphilitic osteochondritis are possible explanations. If osteomyelitis is the cause, the white blood cell count is usually elevated, with predominance of polymorphonuclear cells. Roentgen examination, though frequently uninformative early in the clinical course, is often useful for later comparisons and may show periosteal elevation and osteosclerotic lesions. Typical cerebrospinal fluid changes of poliomyelitis are not present, normal deep reflexes are usually demonstrable, and, although some meningismus may be present, true nuchal rigidity is not found. Finally, repeated blood cultures should yield the causative bacteria.

Trauma without infection can be a confusing cause of apparent paralysis. Here again, normal reflexes, absence of other signs of illness, a history of injury, and local manifestations, such as swelling and tenderness, are usually adequate to confirm the correct diagnosis.

Infrequently in very young patients the pseudoparalysis of scurvy or of syphilitic osteochondritis must be excluded. Having considered either possibility, however, a dietary history, roentgen examination, and serologic tests for syphilis serve to resolve diagnostic doubts.

The differentiation of rheumatic fever from poliomyelitis has not been a problem in my experience, but both the splinting of a painful rheumatic joint and the unwillingness of a child with chorea to exhibit his difficulty have been cited as causing confusion. Either can be excluded by careful physical examination.

Among the numerous causes of peripheral neuritis are lead poisoning, diphtheria, thiamine deficiency, ingestion of some of the newer insecticides,[5] and even botulism. Only the first two will be discussed. Polyneuritis resulting from lead intoxication is relatively infrequent in children but is commoner in adults. After an insidious onset in young patients, the signs of acute poisoning resulting from an extreme degree of intracellular edema in the central nervous system may be so spectacular that the child is brought to medical attention promptly and not only is given treatment but is removed from further exposure to lead. Evidences of increased intracranial pressure are striking, and frequent, if not continuous, convulsive episodes may precede the appearance of deep coma. In chronic lead poisoning, weakness, or paralysis, first appears in muscle groups that are most used, such as dorsiflexors of the foot, and typical peripheral neuritis develops in a symmetrical and generalized distribution. A history of exposure together with basophilic stippling of erythrocytes in the peripheral blood, measurement of lead excretion in the urine and its level in the blood, and extremely dense epiphyseal lines on roentgen films established a diagnosis.

Peripheral neuritis following diphtheria is an important though relatively infrequent problem. Its obvious association with preceding diphtheria may be obscured by appearance of the complication three to six weeks after the acute illness. Bulbar signs entirely similar to those of poliomyelitis generally appear first. Palsies of the 9th, 10th, and 12th cranial nerves are frequent. Head drop, also a frequent finding in poliomyelitis, is characteristically present. If, however, the Schick test is positive and, in addition, ocular paralyses develop, diphtheria is to be strongly suspected. Frequently ptosis appears, and accommodation is lost. Skeletal paralysis appears last and is widespread and bilateral, and deep reflexes are absent. Paralyses persist for varying periods of weeks or even months, and quite typically recovery takes place in reverse order, the last muscles to become involved are the first to recover.[6] Pain, which can be such a distressing feature in poliomyelitis, is not prominent in postdiphtheria paralysis. Although protein is usually increased, there is no remarkable pleocytosis of the cerebrospinal fluid. Complete recovery can be assured to all survivors.

VIRUS INFECTIONS

Acute infectious neuronitis, or Guillian-Barré syndrome, is uncommon and poorly understood. It has even been described following diphtheria.[7] As defined, it is an ascending type of symmetric paralysis associated with an increase in protein content of the cerebrospinal fluid, but without parallel increase in cells. Paraesthesias and areas of anesthesia are usually present. Paralytic involvement most commonly affects the proximal portions of the extremities, and bulbar signs are late to appear. In its classic form, the syndrome is not difficult to recognize, the albuminocytological dissociation furnishing an obvious clue. A greater frequency in winter than in summer months may also be helpful in diagnosis. The fact that acute neuronitis often begins a few days after an upper respiratory infection might remind one of the so-called biphasic course that is seen in approximately one-third of all cases of poliomyelitis. Actually, coryza, cough, and nasal obstruction are not prodromal symptoms of poliomyelitis, and their occurrence at the beginning of an illness may even suggest consideration of other diagnostic possibilities.

Acute neuronitis, not conforming in important respects to the Guillian-Barré syndrome, is sometimes encountered and is virtually impossible to diagnose when poliomyelitis is also present in a community. To complicate the issue further, recurrent bouts of neuronitis have been reported. As an example, one physician's wife had three such paralytic attacks in a period of as many years with complete recovery from each.

Choriomeningitis, mumps meningoencephalitis, Coxsackie virus disease, and some mild cases of arthropod-borne virus encephalitis may be more difficult if not impossible to differentiate from poliomyelitis. In general, the cerebrospinal fluid blood cell counts are higher in the case of both mumps and choriomeningitis. The latter disease, typically of sporadic occurrence, begins with grippal illness and can only be suspected clinically. Mumps meningoencephalitis is far more frequent and may be either epidemic or endemic. The fact that many patients with typical mumps parotitis have an increase in blood cells in the spinal fluid and the further fact that meningoencephalitis can occur in the absence of parotid involvement deserve emphasis. Paralyses are infrequent in arthropod-borne viral encephalitis and are also extremely rare with the complications of mumps, with Coxsackie infection, or with choriomeningitis. Also, the complement fixation test for poliomyelitis of Casals and Olitsky[8] promises to be extremely useful in excluding diseases of this type. The greatest problem then in differential diagnosis concerns nonparalytic poliomyelitis and, generally speaking, is best resolved by serological examination of blood samples during both the acute course and convalescence.

The clinical picture of viral encephalitis, particularly of arthropod-borne types, varies to such an extent that generalizations are dangerous. Within the continental United States, we are primarily concerned with three types; namely, St. Louis encephalitis and eastern and western equine encephalitis. Differentiation from poliomyelitis begins with a carefully taken history together with knowledge of pertinent epidemiological data. It has been established that mosquitoes and other insects, with birds acting as intermediate hosts, spread these diseases. Eklund,[9] in the Minnesota epidemic of 1946, showed clearly that the incidence of equine encephalitis ceased abruptly after the first hard frost killed most of the insect population, whereas the incidence of poliomyelitis did not. Outbreaks occur in hot weather, are usually of shorter duration, and affect fewer persons than is the case of poliomyelitis. Although it does not necessarily follow that equine encephalitis parallels the occurrence of the disease in horses, this is often true and may be helpful in recognizing initial cases in an epidemic.

In this group of diseases, wide variation between the extremes of asymptomatic infection and fulminant and rapidly fatal illness are known to occur. In all types, stupor and even coma are common in contrast to the mental alertness of most patients with poliomyelitis. Important exceptions provided by patients with bulbar and respiratory poliomyelitis are attributable to impaired pulmonary ventilation with hypoxia and accumulation of carbon dioxide. Paralysis of respiratory muscles, obstruction of the airway, failure of the central respiratory center, or a combination of these factors may be responsibile. Convulsions that are not a part of the symptomatology of poliomyelitis are typical, severe manifestations of infections with St. Louis or either strain of equine encephalitis virus. Although spinal fluid findings are not helpful in distinguishing these diseases, one may occasionally be helped by finding marked increases in intracranial pressure with bulging fontanelles in infants and young children and papilledema in older patients. An initial temperature of 105 F and higher exceeds expected readings of 101 to 103 F in poliomyelitis. Headache, backache, and muscle, as well as bone, pain are common, again surpassing in severity similar complaints in poliomyelitis. Photophobia is a significant differentiating point favoring the diagnosis of arthropod-borne virus infection.

Tetanus is not associated with flaccid muscular paralysis but on occasion can be confused with poliomyelitis. Tonic spasms give rise to apparent stiffness of the neck and back and may be associated with severe muscle pain. Trismus and risus sardonicus are frequent and helpful clinical signs. Although a wound that served as portal of entry may have been trivial and unnoticed, it should be looked for, and a careful history of immunizations or a record of the patient having received tetanus antitoxin within two or three weeks of onset should be sought. Finally, the initiation by a variety of mild stumuli of generalized muscular spasms, with the extremities and trunk held in extension, is sufficiently typical to warrant a clinical diagnosis.

Last and perhaps most important is the differential diagnosis of bacterial meningitis and preparalytic or nonparalytic poliomyelitis. In addition to reduction of sugar in the spinal fluid, the blood cell count in bacterial meningitis is usually high enough to impart turbidity to the specimen, and smears reveal not only a predominance of polymorphonuclear leukocytes but usually the causative bacteria. Cultures of the spinal fluid later confirm the suspected identity of the offending organism. Actually, meningitis and poliomyelitis are quite dissimilar, but in each stiffness of the neck is an early clinical sign. The patient with meningitis is sicker and does not respond as readily as the patient with poliomyelitis. The temperature is usually higher, and, in addition to nuchal rigidity, evidences of cerebral involvement become apparent. The Babinski sign is elicited, and convulsions are frequent, but early paralyses are rare. Muscle tone is often increased, chills are not unusual, and evidences of increased intracranial pressure are to be expected. Tuberculous meningitis represents a notable exception to these statements. The blood cell count is not so high as in more acute types of infection, and except at the very onset the predominating blood cells are lymphocytes. Until very recently, effective techniques for culturing the tubercle bacillus were not available. Demonstration of tuberculous involvement elsewhere strongly suggests a similar etiology of the meningitis. Finally, the onset of symptoms is usually more insidious. Personality changes frequently appear first and are followed after days or weeks by meningeal signs and then by encephalitic manifestations.

ILLNESS CAUSED BY FEAR

Before concluding this discussion, mention of "poliophobia" is warranted. During epidemics, dread of poliomyelitis is so great that any type of complaint may be interpreted as a dangerous evidence of disease. Prodromal symptomatology is involuntarily imitated, hysterical paralyses may appear, and hyperventilation, or feelings of suffocation, may suggest respiratory involvement. Complete aphonia and a sluggish gag reflex may be encountered. Persons may complain of a lump in the throat and may fear that bulbar involvement is developing. When these persons are examined, ingenuity may reveal that an apparently paralyzed muscle actually functions in one type of movement though not in another. Deep tendon reflexes are normally brisk, and frequently areas of hyperesthesia or paraesthesia having bizarre distribution are described. None of the abnormal findings persist during sleep, temperature is not significantly elevated, bladder and bowel function are normal, and paralytic findings often are altered by suggestion. Demonstration for the patient's benefit of normal spinal fluid has not been particularly helpful in my experience. An understanding attitude and repeated physical examination to confirm the absence of real disease, together with prescription of rest, are usually adequate to allay anxiety and this eradicates signs of illness.

SUMMARY AND CONCLUSIONS

The commonest problem faced by the physician, with respect to the diagnosis of poliomyelitis, is differentiation of nonparalytic or atypical types of poliomyelitis from other obscure infections of the central nervous system. Here the examination of paired serums, one obtained during the acute course and one during convalescence, may be crucial. Lumbar puncture can be of great help when real diagnostic doubt exists, but it is superfluous when diagnosis is supported by typical clinical features. In differential diagnosis, not only those diseases that are associated with paralyses and those primarily involving the central nervous system must be considered, but also flu-like illnesses and even "poliophobia" must be excluded.

THE AMERICAN BOARD OF INTERNAL MEDICINE

CHAIRMAN'S ADDRESS

Truman G. Schnabel, M.D., Philadelphia

The American Board of Internal Medicine was founded by the cooperation of the Section on the Practice of Medicine of the American Medical Association and the American College of Physicians in 1936. It has continued to function under their sponsorship and by authorization of the Advisory Board for Medical Specialties since that year. For many years before, an increasing number of physicians had limited their practice to special fields of endeavor after special study and application to practice. There was the physician, however, who was reputed to be a specialist according to the talk of the town; this was initiated on the physician's own prompting, not because he had had adequate preparation and experience or could conduct a really good follow-up on his patients. During these same years, genuine and self-styled specialists took on their role largely because medicine and medical education were making great strides that made it impossible for one man to deal with the whole field of medicine in a satisfactory fashion. It can be said, too, that even then "specialist" had become a by-word and that the patient public was pressing indiscriminately for "specialist" attention.

As a result of this trend, the Council on Medical Education and Hospitals had to concern itself with standards of education and training for special fields in practice to the end that most of the American boards emerged by its approval and that of the newly established Advisory Board for Medical Specialties. The Board of Ophthalmic Examinations, as the present American Board of Ophthalmology was originally named, had been functioning since 1917 and, along with three other working boards, served in principle as the pattern for all other boards that were to follow.

DETERMINATION OF COMPETENCY

In effect, these were and are agencies created solely for the determination of special competency on the part of physicians who have usually gone through training periods of varied duration. For the estimation of such competency, no one thought of any better technique than that of formal and unprejudiced examination. Whatever may be said of examinations, no one has suggested, so far as I know, a better means of carrying out the objectives of the special boards. Board members would be greatly relieved and would welcome any suggestions that would enable them to pass fairer and better judgment on candidates than are now made by evaluation of written and oral performance. Examinations remain essential to all effective procedures of training and instruction.

In tracing developments before the organization of our dually sponsored board, Dr. Walter Bierring, in his history of the board,[1] makes it quite clear that, in addition to sharing a common heritage with its companion boards, it also shares their objectives with reference, of course, to internal medicine. Bierring's fine history also records the deliberations of the regents of the American College of Physicians for some years before the formation of the board. The minutes show the early concern with examinations as a means of determining eligibility for fellowship. The college had its prototypes in the Royal Colleges of Physicians of London and Edinburgh, and so, in emulation of these distinguished bodies, rigid examinations were considered as a means of revealing unusual accomplishment on the part of aspiring candidates.

After such considerations and others too, came the final resolution to organize, with the Section on the Practice of Medicine, an "American Board for the Certification of Internists." Through it all, the founders obviously felt that the new board would establish needed criteria and identification for the qualified internist. John Musser, in enthusiatic support of the project, anticipated "A far-reaching effect upon appointment to hospital staffs, departments of internal medicine and other institutional positions." In retrospect, the salutary effects that he had in mind came about but, unfortunately, the organization of medical staffs came with them so that noncertified physicians are barred from top-ranking positions. The board deplores such ill-advised policy as it does the application of differential emoluments, appointment, or promotion based on board certification. It was, however, affirmed by

---

Read before the Section on Internal Medicine at the 102nd Annual Session of the American Medical Association, New York, June 3, 1953.

[1] Bierring, W. L.: History of the American College of Physicians, Philadelphia, American College of Physicians, 1940, p. 87.

all that the undertaking would have a telling influence on graduate education, on internist performance, and ultimately on patient care.

ADVANCED THINKING AND PHILOSOPHY

The currently published data pertaining to the Board of Internal Medicine,[2] with regard to its organization, purposes, and eligibility qualifications for certification, still reflect the advanced thinking and philosophy of its first members (Reginald Fitz, Jonathan C. Meakins, Ernest E. Irons, G. Gill Richards, John H. Musser, O. H. Perry Pepper, Walter L. Bierring, William S. Middleton, and David P. Barr). That "Preparation must be based on years of continuous thoughtful study" and that "Time and training are but a means to the end of acquiring a broad knowledge of internal medicine" are fundamentals that apply as much today as they did 17 years ago. The possession of a sound knowledge of the basic sciences as applied to disease was asked of examinees and has been expected of them by the board over the intervening years. No other suggestions, however, have been made with regard to the substance of training programs, and no suggestions have ever been proposed concerning methods of teaching. In other words, with its function well defined as an examining one, the board has never touched the field of medical education directly, either undergraduate or graduate. There has always been the recommendation to prospective candidates of a sufficiently long residency in a good location and under well-fitted critical teacher-physicians, with the added admonition "that the responsibility of acquiring knowledge rests with the candidate and the responsibility of maintaining the standards of knowledge required for certification rests with the board." Better than all else was the fact that the first board members considered it unwise to lay down rigid rules for candidates with regard to location and mode of training. Schooling was left up to the professional staffs of hospitals and medical schools. The minimum time requirement acceptable for training purposes was set at five years after internship, but a longer period was advised. Only general principles then were set forth that might always apply to a developing specialty in a changed and changing order.

LIBERALIZATION

While the original board's thinking and philosophy have prevailed until this time, a changing order did require liberalization of eligibility rules for admission to examination when a number of plans were provided for likely trainee situations. In doing this, the board did not modify its standards of examination. There was the definite minimum time requirement of three years residency discipline and two years in practice, but a number of time grooves, so to speak, were created into which trainees fit according to varying circumstances. These new plans were arranged in recognition of the fact that capable persons might do as well by preparation over a longer period of time with less intensive application to residency training and more to actual practice, wherever that might be. It was also thought that variable preparation plans might be welcomed because of unavailability of suitable residencies and/or because of personal or economic reasons. Moreover, it was believed that such liberalization of time requirements would enable candidates to go on simultaneously with other objectives, such as research and teaching. It was felt that a background of certified capability in the field of internal medicine would strengthen potentialitites for the candidate in whatever field of endeavor he might finally find himself. I am sure that the provision of additional plans for admission to examination was a considerate and wholesome one appreciated by prospective candidates. In all of this, as I remember it, Drs. William McCann, Alex Burgess, and Cecil Watson, past members of the board, were prominently identified.

EXAMINATIONS

In 1948, Dr. Watson, as chairman, addressed this Section on Internal Medicine on "Some Activities and Impacts of the American Board of Internal Medicine." [3] His was a masterly presentation of the subject and, as I see it, left nothing of importance for amendment five years later. It was most revealing in exposition and should have clarified many erroneous impressions with respect to the board's constitution and activities. A good portion of the address was devoted to a clearly phrased description of the multiple choice type of written examination that had recently replaced the essay type. Here, too, in accord with a changing order, there was the need to follow the best psychological and pedagogic opinion and advice of the day. Dr. Watson brought to the situation the benefit of his own experience with this objective and comprehensive type of examination and was energetic in its early implementation. The board quickly appreciated the inherent advantages in this kind of an examination over those of the essay type and was soon convinced of their superior value. The production of a multiple choice examination requires much time, thought, and checking, both before and after the test. The composition of questions may be so affected that the answers will reveal factual knowledge, experience, and ability to reason or analyze as may be required. Good questions so submitted are sharply discriminating. The board has support for the use of this examination in a well-controlled study reported by Cowles and Hubbard who concluded that "Objective test scores correspond much more closely with the long-term evaluation of students in internal medicine by their own instructors than do the essay test grades." [4]

The board, of course, still continues to carry out the second part of the examination at the bedside of the patient, after the examinee has had a reasonable amount of time to obtain historical data and to do physical examinations. This has always been regarded as a clinical or practical examination and is a procedure that time and experience have shown to be helpful and valuable in measuring the qualifications an internist should possess. There is no need of relating the observations that a bedside examiner can make or the conclusions he may derive therefrom, except to say that here approach, poise, ideas, judgment, and consultantship may be quite evident.

---

[3] Watson, C. J.: Some Activities and Impacts of the American Board of Internal Medicine: Chairman's Address, J. A. M. A. **138**: 257 (Sept. 25) 1948.

[4] Cowles, J. C., and Hubbard, J.: A Comparative Study of Essay and Objective Examinations for Medical Students, J. M. Educ. **27**: 14 (May, *part 2*) 1952.

Members of the board and official examiners recently appointed for the first time have due regard for examinees as colleagues in medicine and are well aware of impressions they, in turn, may make on examinees. So it is that they do all they can to allay anxiety and tensions brought by candidates to the occasion, to say nothing of real mental blocking. Unfortunately certification may be his big and immediate objective for various reasons, an objective he must sooner or later learn is a limited one. The examiner needs, at times, to decide whether the "flustered" and "flurried" candidate will after all possess enough "phlegm" in medical emergency and consultation. Happily there are those who are possessed of Oslerian "imperturbability" at the bedside and during the written test as well.

It is interesting to note that the board brings to its job continued discussion, exploration, and analysis of function, which is admittedly not infallible. During the past five years, however, analytical data show an ever-improving testing efficiency. Data also reveal an increasing complement of the written and oral tests and that measurements other than those derived by objective examination are developed at the bedside. The board's deliberations and study still confirm the good judgment of insisting on primary certification in internal medicine before granting approval to competency in the subspecialties of allergy, cardiovascular disease, gastroenterology, and pulmonary disease. There is every reason to believe that these more sharply limited subspecialties should be erected only on the broad base of internal medicine.

CERTIFICATION

It is of interest to know that 29 written and 60 oral examinations have been organized by the board since its inception. The board has passed favorably on the competency of 6,090 internists by means of examination. Originally, 1,945 physicians were specially certified because of qualifications that placed them in adviser and founder groups. This makes a total of 8,035 certified internists to date. In this number are included the hundred or more internists who were certified on the basis of examinations organized and executed for medical officers in the European theatre operation during World War II. The direction of this effort was carried out by Dr. William S. Middleton, then Colonel Middleton, with the assistance of 27 officers, who were diplomates of the board, acting as guest examiners. This distinguished achievement suggests quite clearly that "in spite of the stress and strain of war, the high standards required of successful candidates were steadfastly maintained." [5]

For some years, the board has certified about 700 men a year, and this number has remained constant for the past three years. New applications continue to be made at a fairly constant rate. Thirty-five men, including the present members of the board under Dr. Walter Palmer's chairmanship, have given large amounts of time, sincere effort, and great thought to the project in the course of these 17 years. During much of this time, the board has had the invaluable assistance of its executive secretary-treasurer, Dr. William A. Werrell, and its librarian, Dr. Victor W. Logan.

STANDARDS OF MEDICAL EDUCATION

All of this, I should say, is reminiscent of what happened when, in 1904 and thereafter, the newly created Council of Medical Education joined with other interested bodies to raise the standards of medical education in this country. They were at a critically low ebb, at the time. For this effort, there was available the great publicity medium of Mr. Abraham Flexner's report, after he had investigated the medical schools of the country for the Carnegie Foundation. The undertaking developed gradually by means of conference, study, inspection, exploration, and change in emphasis. The results of that enterprise are apparent today in what has already been accomplished and in the continuing advance of medical education, especially at the undergraduate level.

The same Council of Medical Education, now entrusted with counciling hospitals as well, was called on to study the problem of specialized practice. The outcome of that enterprise is also apparent. Well-organized and well-directed training programs are provided in many hospitals throughout the country. Interest in staff conferences of all types, patient rounds, abstract groups, and lectures is very impressive. Medical meetings at national, regional, and state levels are increasingly well attended year after year. Postgraduate courses are in demand, and enrollments are complete.

Even casual or indifferent exposure to such a wealth of scientific presentations in meeting alone must have some influence on the professional achievement of a great many physicians. More than this, it is especially significant that our 6,090 physicians have found, in this array of training opportunity, enough substance for a demonstration of their fitness as internists. This would suggest that they derive much by postgraduate effort.

The influence of this latter group on the professional and lay communities of their residence, by reason of spirit, leadership, confident approach to patient care and able consultation is well appreciated by those who were on hand before the board's institution. They have not forgotten the unfortunate features of medical practice before that time. It is easy to forget the greater faults in the old when seeking faults in the new.

CONCLUSIONS

It can be said that, as members of this section and as fellows of the American College of Physicians predicted, patient care has been advanced by an organized and functioning board of internal medicine. This occurred because of an improvement in professional ability achieved by a great forwarding in postgraduate education and all that it connotes. The American Board of Internal Medicine has adhered to the common objectives it shares with the other specialty boards and, in particular, has carried the responsibility for the identification of internists who successfully meet the test of examination.

1704 Pine St. (3).

RECURRENCE OF ULCER AFTER VAGOTOMY

Stephen J. Stempien, M.D., Beverly Hills, Calif.
and
Joseph A. Weinberg, M.D., Long Beach, Calif.

Adequate therapy of duodenal ulcer should not only accomplish healing of the ulcer but should prevent its recurrence. Since the advent of vagotomy as a surgical treatment of duodenal ulcer the question of its effect on ulcer recurrence has been raised repeatedly. The literature on this subject is inadequate, and in most of the reports the data are inconclusive. For example, a report by Weber, Goldblum, and Gregg[1] cites three cases of gastric ulceration following vagotomy. No insulin tests were done in two of these cases, and in the third case the insulin test would be considered by us to be inadequate, since the blood sugar level attained was only 58 mg. per hundred cubic centimeters. In addition, this patient had a gastroenterostomy, which in our experience frequently causes false negative results in insulin tests. Dragstedt[2] states that persistence or recurrence of duodenal or gastrojejunal ulcer is almost invariably due to incomplete vagotomy as evidenced by physiological tests. Deaton, Postlethwait, and Bradshaw[3] have shown that, in dogs, persistent negative responses to insulin occur in both the secretory and motor phases for as long as two years after vagotomy.

EVALUATION OF THE INSULIN TEST

Our experience indicates that the insulin test cannot be relied on in all cases. A positive test is a reliable indication of incomplete vagotomy. We consider a response positive when the free hydrochloric acid rises over 20 degrees beyond the highest fasting level. There are many factors other than complete vagus section that produce a negative insulin test.

In the immediate postoperative period there is a refractory state equivalent to a temporary suppression of gastric secretion. Many of our patients have shown negative responses to insulin tests in the early postoperative phase; later, when the trend of the gastric function was toward normal, the same patients had positive results. Gastric retention contributes to false negative results, because retention of mucus, food, and other substances acts as a buffer system for the neutralization of acid stimulated by insulin injection. In marked pyloric obstruction of a patient with active duodenal ulcer, the basal acid values as well as the acid responses to histamine or insulin are often low. They may even be absent in tests made by the conventional titration method. After adequate decompression, the acid values may be high. A similar situation is seen when gastric dilatation occurs as a result of the loss of gastric tone after vagotomy. Regurgitation of alkaline secretion from the duodenum or through the stoma may cause tests to be unreliable. If the technician attempts to obtain all of the secretion of the stomach, additional secretion is obtained from the duodenum and jejunum either through the pylorus or through the stoma. In our experience the gastroenterostomy stoma is more likely to cause disturbing alterations in secretory acid values than pyloroplasty, although changes due to pyloroplasty are seen.

The level of hypoglycemia attained may also affect results of insulin tests. In our opinion the response to insulin is not predictable in every patient. Some patients react markedly to 15 units of insulin administered intravenously and show sharp declines in blood sugar levels as well as high rises in acid values. On the other hand, some patients are refractory to that amount of insulin given intravenously. In these patients the blood sugar level may not fall rapidly or to a very low level, and the acid response may not be as good as expected. When the blood sugar falls in excess of 50% of the basal fasting value, the insulin test is much more likely to be reliable. In some patients the hypoglycemic response is delayed, but in the average patient the reaction occurs promptly and usually is evident within 30 minutes after insulin injection; it is at its height 45 minutes after injection and then gradually tapers off. In some patients, however, the height of the reaction does not occur until one hour after injection, and in a few the height of response may not occur until one and one-half hours after injection. In order to obviate these difficulties, the test should be repeated if it is negative after the conventional one hour of gastric drainage, and gastric drainage as well as blood sugar sampling should be continued for as long as one and one-half hours after the second injection of insulin.

In our experience 60% of patients with duodenal ulcer who have had a gastrectomy or a gastroenterostomy have postoperative gastritis on previously normal mucosa or on previously hypertrophic mucosa. The usual effect of this inflammatory reaction is depression of acid secretion. Thus in some cases the absence of an adequate acid response after such surgical procedures may indicate the presence of gastritis rather than complete vagotomy.

REPORT OF CASES

We have studied the problem of recurrence of ulcer and hemorrhage after vagotomy by reviewing patients who were operated on after vagotomy because of the suspicion of recurrent ulcer or the presence of hemorrhage. In all of these repeat operations surgical indications were considered to be present.

CASE 1.—N. F. H., a 29-year-old man, had a gastroenterostomy elsewhere in 1942. A roentgenogram showed a high gastroenterostomy stoma and a deformed duodenal bulb. Gastroscopic findings were normal, but the gastroenterostomy stoma was not seen. Histamine gastric analysis showed a rise of free hydrochloric acid to 125 degrees. Because the patient had persistent pain that did not respond to medical therapy,

[3] Deaton, W. R., Jr.; Postlethwait, R. W., and Bradshaw, H. H.: Gastric Secretion and Motility in Dogs Post-Vagotomy—Two Year Studies, Gastroenterology **17**: 72 (Jan.) 1951.

a transthoracic vagotomy was performed in April, 1948. He returned in July, 1948, complaining of epigastric pain, fullness, and a weight loss of 23 lb. (10.4 kg.). A roentgenogram showed a high gastroenterostomy and gastric retention of an estimated 80% in 24 hours. An insulin test was negative; after injection of 15 units of insulin, the acid values remained at 10 degrees at the 30 and 45 minute periods. The blood sugar level was 27 mg. per hundred cubic centimeters. Gastric resection was done because of the gastric retention, and a stomal ulcer and an intact right vagus nerve were found. Histopathological examination confirmed the surgical findings.

Case 2.—C. G. C., a 46-year-old man, had vagotomy and gastroenterostomy in May, 1947, because of severe repeated hemorrhages from a duodenal ulcer. The insulin test was negative in the immediate postoperative period, indicating that complete vagotomy had been done. The patient returned in March, 1951, because of epigastric pain, vomiting, and hemorrhage. He was again explored surgically, and no ulcer could be seen. The gastroenterostomy was taken down, and pyloroplasty was performed, but no search for vagus fibers was made. The preoperative insulin test was considered to be negative or equivocal, because the rise in free hydrochloric acid after insulin injection was only 10 degrees over fasting levels. The blood sugar level attained was 24 mg. per hundred cubic centimeters after a fasting value of 92 mg. The patient returned in September, 1951, with the complaint of recurrent hemorrhages. Insulin tests were positive. A roentgenogram showed a deformed duodenal bulb with an ulcer crater. A transthoracic operation was performed, and the left vagus nerve was found to be intact. Only the right vagus nerve had been divided at the first operation.

Case 3.—G. R. U., a 34-year-old man, underwent vagotomy and gastroenterostomy in 1948 because of melena and epigastric pain due to duodenal ulcer. The patient returned in July, 1951, complaining of severe, recurrent epigastric pain and a loss of 20 lb. (9.1 kg.) over a period of six months. A roentgenogram revealed jejunal ulcer. The insulin test was positive. A second operation was performed, and the presence of a jejunal ulcer was confirmed. An intact vagus nerve was found and divided; the gastroenterostomy was taken down; and a pyloroplasty was performed. Subsequent pathological examination confirmed the diagnosis of jejunal ulcer as well as the presence of the vagus nerve fiber. Several months after the second operation the insulin test was negative.

Case 4.—W. C., a 46-year-old man, had a vagotomy in December, 1946, because of melena due to a duodenal ulcer. He returned in April, 1948, complaining of epigastric pain. A roentgenogram showed no retention but disclosed a duodenal deformity with crater. An insulin test was positive, with 49 degrees of free hydrochloric acid rise above basal levels. At operation, a large right vagus nerve and one small nerve filament were found. The nerves were divided, and gastroenterostomy was done. Three months after operation the insulin test was negative; however, gastroscopy revealed development of superficial gastritis. This patient has had no evidence of recurrent ulceration.

Case 5.—L. L. P., a 37-year-old man, underwent vagotomy and pyloroplasty in November, 1950, because of duodenal ulcer with obstruction. He returned in February, 1951, complaining of distention, epigastric pain, and hematemesis. The insulin test was positive, showing 23 degrees of free hydrochloric acid rise above fasting basal levels. This occurred despite the fact that the insulin reaction was only slight and the blood sugar drop was not great. A roentgenogram showed an atonic stomach with minimal peristalsis and a deformed duodenal bulb with crater. Surgical exploration revealed a duodenal ulcer penetrating the pancreas. Numerous adhesions at the esophageal hiatus precluded an adequate search for vagal fibers. Subtotal gastrectomy was performed.

Case 6.—J. G. M., a 45-year-old man, had vagotomy and pyloroplasty in September, 1951, because of hemorrhage from a duodenal ulcer. The patient returned in May, 1952, because of severe hemorrhage. He was operated on immediately, without preliminary studies. At operation a duodenal ulcer and an intact vagus nerve were found. The nerve was divided, and a partial gastric resection was performed. Subsequent pathological examination confirmed the presence of a duodenal ulcer as well as an intact vagus nerve.

Case 7.—D. D., a 25-year-old man, had vagotomy and pyloroplasty in March, 1951, because of severe and repeated hemorrhage from a duodenal ulcer. He returned in June, 1952, with another attack of melena. A preoperative insulin test was considered equivocal, the hydrochloric acid rising only 13 degrees one hour after insulin injection. At operation, scarring of the pyloroduodenal segment was seen, with no evidence of active ulceration. One small nerve fiber was found intact at the hiatus. A subtotal gastrectomy was performed, and pathological examination of the resected specimen showed chronic hypertrophic gastritis, submucosal vascular congestion, and petechial mucosal hemorrhages.

Case 8.—W. C. M., a 52-year-old man, underwent vagotomy and pyloroplasty in September, 1947, because of repeated hemorrhages associated with duodenal ulcer. He returned in July, 1948, with recurrence of hemorrhage. An insulin test was positive, and a roentgenogram showed a duodenal deformity with 20% retention at the end of six hours. A transthoracic vagotomy was done, involving the resection of the intact right vagus nerve and three small nerve filaments. The presence of nerve fibers was confirmed histologically.

Case 9.—J. D. R., a 46-year-old man, underwent vagotomy and pyloroplasty in August, 1951, because of recurrent hemorrhages associated with a duodenal ulcer. He returned in November, 1951, complaining of epigastric fulness and pain. A roentgenogram disclosed a markedly deformed duodenal bulb with an ulcer crater and 30% retention of barium at the end of 24 hours. An insulin test showed no rise in free hydrochloric acid after insulin injection; however, undigested food was found in all gastric specimens, which made the insulin test invalid. On surgical exploration, a duodenal ulcer was found penetrating the liver. Because of adhesions, no search was made for additional vagal fibers, but subtotal gastrectomy was performed.

Case 10.—W. H. B., a 53-year-old man, had vagotomy and pyloroplasty in November, 1951, because of recurrent hemorrhages associated with a duodenal ulcer. A deep ulcer crater was found penetrating the pancreas. Both the right and left vagus nerves were identified and divided. Three weeks later, while the patient was still in the hospital, he had a massive hemorrhage. Subtotal gastrectomy was done. An actively bleeding duodenal ulcer was seen, but undivided vagal fibers could not be identified. Insulin tests could not be carried out prior to the second operation because of the patient's serious condition.

Case 11.—J. H. R., a 28-year-old man, had a transthoracic vagotomy in April, 1947, because of recurrent hemorrhages from a duodenal ulcer. He returned in May, 1951, with the complaint of pain and vomiting. An insulin test was positive, and a roentgenogram showed duodenal deformity with an ulcer niche. At surgery, an intact right vagus nerve, a healing duodenal ulcer, and a partial pyloric stenosis were found. The right vagus nerve was divided, and a pyloroplasty was performed. The patient returned in January, 1952, because of tarry stools. Preoperative insulin studies were considered inadvisable because of the evidence of bleeding. A preoperative roentgenogram showed a deformed duodenal bulb but no ulcer crater. The deformity was interpreted as a pseudodiverticulum. At surgery, scarring of the anterior duodenum was found. In addition, the surgeon described what he thought was an ulcer but stated that no active bleeding was seen at this site. A subtotal gastrectomy was done, including resection of the area of suspected ulceration. Subsequent pathological examinations showed that no ulcer was present, and the defect seen at surgery was interpreted as being the result of healing of the pyloroplasty and the duodenal ulcer. The resected specimen showed hypertrophic gastritis with many mucosal hemorrhages.

SUMMARY

Duodenal ulcer remains healed almost without exception after complete vagotomy. We have encountered only one possible exception in over 700 patients who have had vagotomy. In this patient, the ulcer was large and had penetrated the pancreas. Recurrence of hemorrhage after vagotomy may not be caused by recurrence of ulcer but may be caused by mucosal hemorrhages associated with hypertrophic gastritis. Using the insulin test, positive roentgenograms, and surgical exploration as criteria for the presence of ulcer and intact vagal fibers, we believe that recurrence of ulceration is evidence of incomplete vagotomy. A positive insulin test is a reliable sign of incomplete vagotomy. A negative insulin test, however, is not always indicative of complete vagotomy; in many instances false negative tests are found in the presence of incomplete vagotomy. The unequivocal demonstration of a recurrent duodenal or stomal ulcer after vagotomy is the best indication of incomplete vagotomy.

HEART DISEASE DISCOVERED ON CHEST MICROFILMS

R. V. Slattery, M.D., Oakland, Calif.

In recent years, the chest microfilm has been used extensively in surveys of large numbers of persons for pulmonary tuberculosis. In some of these surveys, it has been noted that many cardiac, as well as pulmonary, abnormalities were found, and, as a result, it has been recommended that the microfilm be used in surveys for the detection of heart disease. No attempt has been made, however, to determine the accuracy of the microfilm in demonstrating heart disease. It was felt that, before its recommendation for this purpose could be justified, a study of its accuracy should be made.

This is a report of such a study. The incidence of heart disease found on clinical investigation of an unselected group of patients was compared with the incidence of abnormal cardiac silhouettes found in the chest microfilms of the same patients.

METHODS

Beginning July 1, 1948, the chest microfilms of all new patients admitted to the medical and surgical outpatient departments of the University of Chicago clinics were examined in sequence by a member of the department of radiology and by myself. The patients were all adults. Any microfilm in which one or both of the examiners thought the heart or great vessels were of abnormal size or shape was noted as showing evidence of heart disease. These small chest roentgenograms were taken on a Picker 70 mm. minograph machine and were read on a General Electric fluorescent viewer.

The clinical records of all patients whose chest microfilms had been examined were then reviewed. Only patients whose records included a complete history and results of complete physical examination, urinalysis, blood cell count, and a Kahn test were retained in the study. This was considered to be the minimum clinical investigation necessary to ascertain whether a patient had heart disease. Electrocardiograms and 14 by 17 in. chest films had been done whenever the clinic physician attending the patient felt that his investigation warranted them. When present, these were employed as aids in determining whether the patient had heart disease. The size of the heart, in those patients who had 14 by 17 in. films, was measured by comparing the long and short cardiac diameters with the height and weight of the patient.[1] In this system of measurement, there is no definite limit beyond which one can always say the heart is enlarged, but it is considered that most persons with hearts measuring 20% or more over size have cardiomegaly.

The histories of those patients found to have clinical evidence of heart disease were further studied to determine which of them had a history of heart disease and which had symptoms that were compatible with heart disease at the time of examination. The symptoms that were considered compatible with heart disease were enlarged heart, high blood pressure, swelling of the ankles, shortness of breath, chest pain, irregular pulse, palpitation, and fatigue. The incidence of heart disease, as determined from the clinical examination, was then compared with the incidence of abnormal cardiac silhouettes on the microfilms.

RESULTS

The microfilms of 800 patients were reviewed. Of these, 682 patients had sufficient clinical investigation to meet the requirements established for retaining them in the study. Of the 682 patients, 56 had clinical evidence of heart disease. Twenty-five, or approximately 45%, of the patients with clinical evidence of heart disease were detected on the microfilms (table 1). Over half of the rheumatic and hypertensive and 43% of the arteriosclerotic hearts were detected. In the cases of coronary artery disease, only 18.2% of the silhouettes were sufficiently altered to be detectable. This significantly lower incidence of detection of coronary heart disease, as compared to that of the preceding groups, was probably due to a greater tendency for hypertrophy to develop in patients with rheumatic and hypertensive heart disease.

TABLE 1.—*Comparison of the Types of Clinical Heart Disease Detected and Not Detected on Microfilms*

Type of Heart Disease	Clinical Heart Disease, No.	Detected on Microfilms		Not Detected on Microfilms	
		No.	%	No.	%
Rheumatic	7	4	57.1	3	42.9
Hypertensive	21	11	52.4	10	47.6
Coronary	11	2	18.2	9	81.8
Arteriosclerotic	14	6	42.9	8	57.1
Syphilitic	2	1	50.0	1	50.0
Congenital	1	1	100.0	0	0
Total	56	25	44.6	31	55.4

A review of the histories of the 56 patients who had clinical heart disease revealed that 51 either knew they had heart disease or had symptoms compatible with

---

The study reported in this paper was conducted in the Department of Medicine, University of Chicago, Chicago.

heart disease. This is an incidence of 90%. In 45 of the 56 patients with clinical heart disease, large chest films were part of the investigation and, in 47, electrocardiograms were done. Five of these electrocardiograms were normal, and the remainder were abnormal. Of the 45 patients of whom large chest films were made, 23 had already been discovered on the microfilm and 22 had not (table 2). As would be anticipated, the tendency to detect an abnormal heart on the microfilm coincided roughly with the degree of enlargement of the heart. It is interesting to note, however, that, in seven of the patients not detected, the hearts were more than 20% over size.

In addition to the 25 patients with clinical heart disease detected in the microfilm, there were 12 patients in whom heart disease was suspected on the microfilms but in whom no heart disease was found on clinical study. In this group, both interpreters felt that the heart was abnormal on the microfilm in seven instances, and only one of the interpreters made the diagnosis in the other five instances. In the group of 25 patients in whom heart disease was seen on the small films, there was approximately the same degree of agreement between the two interpreters; 60% of the cardiac abnormalities were detected by both and 40% by one. This tendency for interpretations of roentgenograms to differ with different readers, as well as with a single reader on different occasions, has also been noted when a search is being made for tuberculosis with chest films.[2]

Table 2.—*Comparison of Heart Size, as Measured on Chest Films, Among Patients with Heart Disease Detected and Not Detected on Microfilms*

Heart Size: % Under Size (—) or Over Size (+)	Clinical Heart Disease, No.	Detected on Microfilm		Not Detected on Microfilm	
		No.	%	No.	%
—40% to —21%	2	0	0	2	100
—20% to — 1%	6	0	0	6	100
0 to +20%	14	7	50	7	50
+21% to +40%	11	5	45	6	55
+41% to +60%	10	9	90	1	10
+61% to +80%	2	2	100	0	0
Total	45	23	51	22	49

COMMENT

Schwartz and Berman,[3] in a survey of 10,549 persons in Cincinnati, found 486 (4.6%) abnormal cardiac silhouettes on the small roentgenograms. Among the 207 who were given clinical investigations, 177 (86%) had organic heart disease. Thompson and Jellen[4] obtained clinical investigations of 1,147 persons whose microfilms indicated abnormal hearts, and they found that 68.9% had heart disease. Comparing these studies with mine, in which the confirmation rate was 68%, one can conclude that approximately three-fourths of the persons who, from the small chest films, are suspected to have heart disease will prove to have such on clinical study.

This present investigation differs from any previously reported in that it shows not only how many abnormal hearts are detectable but also how many are undetectable, or missed, in interpretation of the chest microfilm. In the series reported here, 90% of the patients with abnormal hearts had symptoms frequently associated with heart disease, whereas only 45% had abnormal cardiac silhouettes on the small roentgenograms. This would indicate that, in making surveys for heart disease, more persons with abnormal hearts would be found if all those with these symptoms, rather than only those found to have cardiac abnormalities on the microfilms, were subjected to a clinical investigation. Further study would be necessary, however, to determine whether surveys of this type would be practical. These findings make doubtful the value of trying to detect cardiac abnormalities on the microfilms of patients being admitted to a clinic or hospital when they will give a complete history as part of their investigation. It does not seem that the chest microfilm should be recommended for use in large surveys for heart disease since it is capable of detecting less than one-half of the cardiac abnormalities. The time and expense involved in such surveys could hardly be justified in a test that has such a limited degree of detection.

SUMMARY

Among 682 persons having chest microfilms and subsequent clinical investigations, there were 56 who had clinical evidence of heart disease. Only 25 (45%) of the 56 with heart disease were noted as having abnormal hearts on the microfilms. There were, in addition, 12 persons who were thought to have abnormal cardiac silhouettes on the microfilms but who did not prove to have heart disease on clinical study. Because of its low degree of detection, the microfilm is not recommended for use in large surveys for finding persons with heart disease.

Correction of Obesity.—Directions for reduction are so simple that they can be presented by the physician and can be assimilated by an intelligent patient in a few minutes. On the other hand, the practical difficulties of carrying out a consistent and long-continued program of reduction are enormous. . . . There is a widespread impression among mothers, encouraged no doubt by many physicians, that to be big is to be strong and healthy. As a consequence, growing children are supplied not only a sufficient amount but actually an excess of food. Habits of overeating are acquired, and admiration for prowess at the table is instilled. There is still current the belief that overweight offers insurance against the development of tuberculosis. More important is the fact that there are vast numbers of people who are dissatisfied, restless and anxious and who substitute overeating for occupation, for love and for unfulfilled sexual desires. Above all, the chief bane of preventive medicine applies to the obviation of obesity as it does to many other corrective measures. This major impediment is the belief, "It can't happen to me," the psychologic attitude that permits excessive smoking of cigarettes by those who know that such a practice may predispose to cancer of the lung and to serious peripheral vascular disease, that permits excessive drinking of alcohol in spite of the realization of its deteriorating effects and that allows the assumption of extraordinary hazards in driving an automobile or in jaywalking on a crowded avenue by those who are well acquainted with the danger.—D. P. Barr, M.D., Health and Obesity, *New England Journal of Medicine,* June 4, 1953.

TOXIC MANIFESTATIONS IN THE ANTABUSE-ALCOHOL REACTION

STUDY OF ELECTROCARDIOGRAPHIC CHANGES

J. David Markham, M.D.
and
Ebbe C. Hoff, M.D., Ph.D., Richmond, Va.

The tetraethylthiuramdisulfide * (Antabuse)-alcohol reaction is an essential element in the indoctrination of the patient in the use of tetraethylthiuramdisulfide (TETD) as an adjunct in the treatment of chronic alcoholism. Recently this drug was released to the medical profession, although much investigative work on its effects is still in process and the full hazards of its use have not been completely established.

The tetraethylthiuramdisulfide-alcohol reaction represents a controlled physiological response, in which there are measurable alterations in the cardiovascular system affecting pulse rate, cardiac output, cardiac stroke volume, the electrocardiogram, and peripheral circulation. Many of these changes have not been investigated, while others have been described in detail.

The present study was undertaken after an extensive clinical experience with the reaction in 519 patients treated in the inpatient service of the Division of Alcohol Studies and Rehabilitation, Department of Health, Commonwealth of Virginia, at the Medical College of Virginia Hospital. The scope of this report is limited to an analysis of the electrocardiographic changes occurring during the tetraethylthiuramdisulfide-alcohol reaction, correlated with other changes observed at the bedside. Accordingly, electrocardiographic tracings were made at intervals during the reaction on 44 patients, representing 221 electrocardiograms.

METHOD

The patients who underwent the tetraethylthiuramdisulfide-alcohol reaction in this series were regular inpatients of the Division of Alcohol Studies and Rehabilitation who volunteered to take the drug. This was the first reaction for each of them. Those chosen for this study were selected from the medically qualified group solely by their rotation on the admission roster. Each patient was prepared for the reaction by taking tetraethylthiuramdisulfide orally near the end of a 7 to 10 day period of hospitalization, 1.5 gm. the first day, 1.0 gm. the second, 0.5 gm. the third, and 0.5 gm. the fourth. On the fourth day whiskey was administered to produce the tetraethylthiuramdisulfide-alcohol reaction. Only those patients who were considered suitable after careful history, physical examination, and laboratory work-up, including hepatic and renal function tests, electrocardiogram, chest roentgenogram, blood sugar studies, and hemogram, were permitted to take tetraethylthiuramdisulfide.

A wide variation in the priming dose of tetraethylthiuramdisulfide has been reported in the literature, with no clear-cut rationale for selecting any one particular routine. A critical evaluation of tetraethylthiuramdisulfide and alcohol dosages is imperative. An attempt must be made to standardize the reaction if results of reactions in various research centers are to be comparable. The dosages used in this clinic are generally lower than most reported, which lends greater significance to the electrocardiographic changes to be reported here. Observations in this clinic have established that these lower priming dosages of tetraethylthiuramdisulfide achieve the therapeutic goal of the tetraethylthiuramdisulfide-alcohol reaction and reduce the hazard.

Two principles are paramount. First, the reaction is used for recognition purposes only and not as a conditioning or a frightening experience. For this reason repeated reactions are hardly ever desirable. The treatment program aims at comprehensive rehabilitation with psychotherapeutic follow-up for at least a year. Second, critical reactions are undesirable. In a series of 560 tetraethylthiuramdisulfide cases, reported by Hoff and McKeown,[1] many critical reactions were encountered when higher doses of tetraethylthiuramdisulfide were used. Since the dosage was modified according to the above schedule in August, 1951, there has been a striking reduction in critical reactions, although the results of treatment in terms of sobriety continue to remain about the same. In other words, there has been a reduction in the severity of the tetraethylthiuramdisulfide-alcohol reaction without altering the end-results of treatment.

In the present study, arterial blood pressure, pulse, respiration, and control electrocardiogram were recorded immediately before the reaction. The patient was then given 30 ml. of whiskey, approximately 90 proof. In occasional cases, where the reaction was too mild to achieve its purpose of recognition, an additional 10 to 15 ml. of whiskey was given. The blood pressure, pulse, and respiration were recorded every 5 minutes and the electrocardiogram every 15 minutes for one hour, unless the patient's condition dictated otherwise. Subjective and other objective data were also recorded as observed.

RESULTS

The patient group consisted of 44 patients of both sexes who were desirous of undertaking a prolonged course of tetraethylthiuramdisulfide therapy as a part of the total treatment program offered and who were found to be physically and psychologically qualified for the tetraethylthiuramdisulfide-alcohol reaction. They were

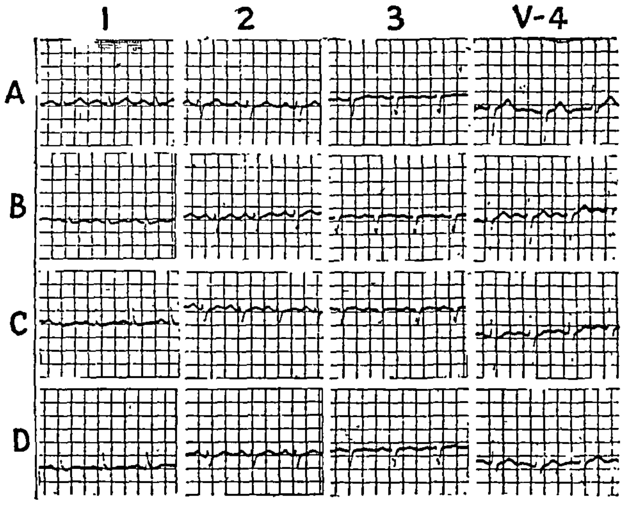
not otherwise selected. The age composition of the group ranged as follows: 20 to 29 years, 5; 30 to 39 years, 19; 40 to 49 years, 17; and 50 to 59 years, 3. There were four women (9% of the total, which roughly corresponded to the admission ratio of women to men), ranging in age from 31 to 48 years.

Major Electrocardiographic Changes in Patients with Antabuse-Alcohol Reaction

Electrocardiographic Changes	No. of Patients	Percentage of Patients
Alteration of T waves in one or more limb leads....	36	82
ST segment deviation in one or more limb leads....	27	61
Lowering of ST segment..............................	23	52
Prolongation of QT interval beyond normal limits for the cardiac rate..............................	18	41
Shortening of PR interval..............................	16	36
T wave changes in lead V-4..............................	12	27
ST segment changes in lead V-4..............................	11	25
Variation in duration of QRS..............................	9	20
Minor disorders of rhythm..............................	8	18
Lengthening of PR interval..............................	3	7
Total patients showing changes..............................	40	91
Total patients showing no changes..............................	4	9
Total..............................	44	100

The reactions experienced by the patients were divided into four categories according to severity: critical, severe, moderate, and mild. There were no critical reactions in this series. There were 7 severe reactions, 12 moderate, and 25 mild.

The major changes observed in the electrocardiograms of these patients during the tetraethylthiuramdisulfide-alcohol reaction are listed in the table. The interpretation of these changes will be discussed later. It is important to note that 40 patients, comprising 91% of the total, showed one or more changes, the majority exhibiting a combination of several. A characteristic pattern of the electrocardiographic changes is illustrated in the figure. In this case a woman, aged 48, showed most of the changes frequently seen during the tetraethylthiuramdisulfide-alcohol reaction. Initial data were: blood pressure 136/88 mm. Hg, pulse 84, and respirations 14; at the height of reaction (30 minutes), blood pressure was 108/56 mm. Hg, pulse 120, and respirations 24.



Electrocardiographic tracing of patient during tetraethylthiuramdisulfide-alcohol reaction. Top line (A) is control tracing before administration of alcohol; second line (B) tracing 15 minutes after ingestion of 30 ml. of whiskey; third line (C) after 30 minutes; and fourth line (D) after 45 minutes, when the reaction was subsiding and the electrocardiogram was returning to normal. The 60 minute tracing (not shown) revealed further return to normal. The changes shown are: shortening of the PR interval, lowering of the ST segment, lowering or flattening of the T waves, and prolongation of the QT interval. Ventricular strain is not evident in this patient.

Seven of the 44 patients experienced a profound drop in blood pressure. In six of these there were major changes in the electrocardiogram, while one showed moderate changes in the electrocardiogram. Twelve of the patients experienced a moderate drop in blood pressure. Of these, five showed major electrocardiographic changes, four showed moderate changes, two slight changes, and one showed no change. Twenty-five patients had a slight or insignificant drop in blood pressure. Of these, 6 showed major electrocardiographic changes, 6 showed moderate changes, 10 showed slight changes, and 3 showed no change. Twenty-four per cent of those with insignificant blood pressure change still exhibited major electrocardiographic changes, and only 12% showed no change at all.

Seven of the patients had a severe reaction requiring supportive measures. All seven showed major electrocardiographic changes. Twelve patients experienced moderate reactions. Of these, six showed major electrocardiographic changes, four had moderate changes, and two had slight changes. Twenty-five patients had mild reactions, but 4 showed major electrocardiographic changes, 7 showed moderate changes, 10 had slight alterations of the electrocardiogram, and 4 showed no change. Therefore, it can be said that a severe reaction will be accompanied by major electrocardiographic changes, but there is a low correlation in the milder reactions between the severity of the reaction and the extent of the electrocardiographic changes.

There was no demonstrable difference between the sexes in the electrocardiographic patterns obtained. All four women demonstrated changes varying from slight to major. Four of the 40 men did not show changes. Any apparent sex difference in degree of change must be considered coincidental, pending analysis of a much larger series containing a much higher number of women.

No significant correlation was found between the electrocardiographic changes observed and the age of the patient. All age groups studied showed electrocardiographic changes during the tetraethylthiuramdisulfide-alcohol reaction. All five of those in the 20 to 29 year age group showed electrocardiographic changes.

COMMENT

Although the literature on tetraethylthiuramdisulfide is large, relatively few reports have dealt with a detailed analysis of the electrocardiographic changes occurring during the reaction. Some reports dismiss the changes lightly in a sentence or two, not analyzing the changes in detail beyond mentioning ST and T wave alterations. A few reports have appeared ascribing serious cardiac complications to the tetraethylthiuramdisulfide-alcohol reaction.

The results reported in our study show electrocardiographic changes of a transitory nature in 91% of cases, and Raby and Lauritzen[2] reported changes in 90% of their series. This may give an exaggerated impression of the cardiac hazards of the reaction. Macklin, Sokolow, Simon, and Schottstaedt [3] reported one case of anteroseptal myocardial infarction following a tetraethylthiuramdisulfide-alcohol reaction. This case has been quoted extensively in the literature on tetraethylthiuramdisulfide, but a critical appraisal of the factors involved has not been made. The case reported by Macklin and coworkers [3] was that of a 45-year-old white man taking tetraethylthiuramdisulfide, who drank ale equivalent to 34 ml. of 90 proof whiskey. He reached the hospital in shock one hour after ingesting the alcohol. The patient was treated by inhalation of Carbogen (95% oxygen with 5% carbon dioxide), parenterally administered caffeine and nikethamide, and elevation of the foot of the bed. In our clinic at present it is standard practice to elevate the foot of the bed; administer large doses of sodium ascorbate, up to 1.5 gm., intravenously, to compensate for the inhibitory effect of tetraethylthiuramdisulfide on oxidative enzymes [4]; give epinephrine (1:1000 solution) in small doses hypodermically, follow with ephedrine intramuscularly or intravenously when indicated; and start an intravenous infusion of glucose in sodium chloride containing parenteral B complex and arterenol if the shock is profound or protracted. Elevating the foot of the bed was the only one of these measures employed in the case reported, and the patient remained in shock longer than three and one-half hours. One cannot, therefore, attribute the unfortunate outcome in this case to a specific effect of the tetraethylthiuramdisulfide-alcohol reaction. Successful antishock measures taken immediately might have prevented the infarction, which can be attributed to prolonged shock, an example of probable infarction without occlusion due to insufficient coronary circulation during the period of shock.

[2] Raby, K., and Lauritzen, E.: Circulatory Changes During Antabus-Alcohol Reaction: Preliminary Report, Nord. med. 42: 1693 (Oct. 28) 1949; abstracted, J. A. M. A. 142: 1028 (April 1) 1950.

Since this course of events is a real danger, the practice of deliberately allowing shock to continue when it occurs during the tetraethylthiuramdisulfide-alcohol reaction cannot be condemned too strongly. Regardless of the cause, shock is a hazardous experience for any patient, and it is a mistake to permit it to continue in the false hope of inducing a greater aversion to alcohol because of an extended shock experience. The tetraethylthiuramdisulfide-alcohol reaction must take place under the closest supervision in the hospital rather than in the physician's office so that any untoward reaction can be immediately and adequately treated.

There is one unpredictable, serious danger encountered in the tetraethylthiuramdisulfide-alcohol reaction. This is the delayed secondary reaction, usually occurring one to three hours after the initial reaction appears to have been terminated. The patient rapidly passes into shock without premonitory flushing but sometimes preceded by nausea or vomiting. This complication is fortunately rarely seen, usually in a patient who has required treatment for shock during the initial reaction. Nevertheless, the gravity of this complication is emphasized by Becker and Sugarman,[5] who reported a death in a 49-year-old white man with sudden respiratory arrest four and one-half hours after ingesting 1 oz. (28.35 gm.) of whiskey under controlled observation. The patient exhibited labile blood pressure prior to the reaction, went into deep shock, and was in a state of collapse for over an hour, but apparently recovered. Two and one-half hours after apparent recovery he suddenly ceased to breathe. The only possibly significant autopsy finding was a bilateral diffuse hyperplasia of the adrenal cortex. The dose of tetraethylthiuramdisulfide administered by Becker was in common use at that time, but higher than that now employed in this clinic.

In this study the changes in the electrocardiogram can be divided into three major groups. The commonest were alterations in the T waves and ST segments, primarily in the limb leads. Perhaps the most significant change was a marked tendency towards prolongation of the QT interval. The third major change was alteration in conduction as manifested by change in duration of the PR interval and QRS complex. The importance of these changes will be considered separately. In addition there were minor disorders of rhythm, consisting mainly of sinus arrhythmia usually associated with increased respiratory excursion during the reaction, and occasionally scattered extrasystoles, which were not considered significant.

T wave changes consisted of lowering, flattening, or inversion. Most frequently, all the limb leads showed changes. Changes were observed as well in lead V-4 in 27% of patients. Lead 3 showed the highest incidence of alterations, singly or in combination (85% of all patients). All limb leads were affected in 34%, leads 1 and 3 in 20%, and lead 3 alone in 14%. Other combinations showed much lower incidence. The ST segment changes consisted of a depression of the entire ST segment, without sagging, and were of the pattern usually associated with ventricular strain.[6] The changes observed were not those of acute coronary insufficiency. In keeping with the greater incidence of T wave changes in lead 3, it was noted that there were changes in the ST segment in lead 3 in 40% of cases, either singly or in combination with changes in the other leads. This is contrary to the findings of Raby and Lauritzen,[2] who reported that most changes involved leads 1 and 2. The over-all pattern is best classified as right ventricular strain, which is consistent with the finding by Raby and Lauritzen of a tendency toward disappearance of a left ventricular preponderance when previously present. Further evidence in support of this concept is provided by the case reported by Jones,[7] in which a 29-year-old male patient died suddenly in a delayed secondary reaction following an initial stormy tetraethylthiuramdisulfide-alcohol reaction. Autopsy revealed acute congestive right ventricular failure as the immediate cause of death.

The significance of a prolonged QT interval is receiving attention in the medical literature. Bellet and Finkelstein [8] have reviewed 168 cases in which it was observed and have noted QT prolongation in the following: electrolyte disturbances, myocardial abnormality or disease, myocardial anoxia, combinations of factors as in hypoglycemia or avitaminosis, and effects of drugs such as quinidine. Lepeschkin and Surawicz[9] analyzed techniques of measurement of the QT interval, and the effects of electrolyte disturbance on it.

[8] Bellet, S., and Finkelstein, D.: Significance of QT Prolongation in Electrocardiogram: Based on Study of 168 Cases, Am. J. M. Sc. **222**: 263 (Sept.) 1951.

It is felt that the prolongation of the QT interval observed in this series is highly significant and deserves emphasis. The predominant changes seen in the electrocardiogram have shown the pattern of right ventricular strain and not acute coronary insufficiency. This is further borne out by the observation in a few cases that the administration of oxygen did not produce any apparent change in the electrocardiographic configuration. One must, therefore, attribute the prolongation of the QT interval to either or both of two factors: electrolyte imbalance with hypokalemia and hypocalcemia and/or myocardial anoxia. There is evidence to support the assumption that part, if not all, of the observed change is due to a direct toxic effect on the myocardium of one of the metabolites involved in the tetraethylthiuramdisulfide-alcohol reaction. As mentioned previously, the rationale for the use of ascorbic acid in the severe tetraethylthiuramdisulfide-alcohol reaction is to compensate for the enzyme blocking effect of tetraethylthiuramdisulfide. It appeared that the electrocardiogram was favorably affected by ascorbic acid, with tendency to return to normal more quickly, although this was tried in an insufficient number of cases to draw definite conclusions. On the other hand, administration of oxygen did not appear to hasten a return to normal. This would indicate that the prolongation of the QT interval is the result of alteration of the internal metabolism of the myocardium and is not due to a deficiency of oxygen supplied to it.

Consideration must be given to the possible role of the tachycardia itself in producing these changes. Numerous studies of the electrocardiogram during and after exercise and other conditions associated with tachycardia fail to reveal the electrocardiographic pattern seen in the tetraethylthiuramdisulfide-alcohol reaction. Smith[10] noted that, in general, most normal persons, including a group with RS-T depression up to 1 mm., had a shorter QT ratio just after exercise than while resting. Yu, Bruce, Lovejoy, and McDowell[11] noted relative prolongation of QT during exercise, shortening during early recovery, and return to resting value during later recovery. In our analysis QT prolongation has been reported only when the values exceeded the upper limits of normal for heart rate and sex, as standardized by Ashman and Hull. The changes observed in the QT interval cannot be regarded as a function of the tachycardia, since the changes occurred over a wide range of cardiac rate and were not seen in control electrocardiograms with similar tachycardia.

As stated, the third type of change in the electrocardiogram was the tendency in a few cases towards altered conductivity. In most of these, there was shortening of the PR interval and a decrease in the QRS duration. These changes can be explained on the basis of the tachycardia produced during the tetraethylthiuramdisulfide-alcohol reaction. At the same time, they emphasize that the reaction does not adversely affect the conduction system of the heart, which again argues against the concept of coronary insufficiency during the reaction. There is heightened conductivity and sluggish myocardial recovery, implying that, in the tetraethylthiuramdisulfide-alcohol reaction, there is a direct reversible toxic influence on the heart affecting the cardiac muscle alone.

SUMMARY AND CONCLUSIONS

Definite changes have been observed in the electrocardiograms of 91% of 44 patients during the tetraethylthiuramdisulfide-alcohol reaction. The principal changes are lowering, flattening, or inversion of T waves; ST segment depression in one or more leads; and prolongation of the QT interval. The pattern of changes is the same as that seen in ventricular strain, mainly right ventricular strain. The pattern of acute coronary insufficiency has not been observed.

There is strong evidence that some of the changes are due to a direct toxic effect on the myocardium of one or more of the metabolic products of the tetraethylthiuramdisulfide-alcohol reaction. This effect is reversible, subsiding with recovery from the reaction, and also responding to the administration of ascorbic acid, but apparently not to oxygen administration.

The changes in the electrocardiogram indicate that tetraethylthiuramdisulfide should be withheld if there is any suspicion of cardiac abnormality. Every attempt should be made to keep the reaction as mild as possible consistent with sufficient severity for recognition by the patient. Shock should be combatted immediately and vigorously, to avoid superimposing the strain of shock and consequent coronary inadequacy on an already toxic myocardium.

Visceral Aspects of Shoulder Pain.—Pain in the shoulder-neck area may arise from abdominal or thoracic viscera. Pain of abdominal origin usually presents no problem in differentiation from pain from orthopaedic causes. However, pain of thoracic origin, particularly that arising from infarction of the diaphragmatic portion of the lung, must always be considered by the orthopaedist confronted with the problem of shoulder-neck pain. . . . Pain in the supraclavicular fossa and top of the shoulder in a patient in a plaster-of-paris splint or in a patient recently operated upon, should be considered due to pulmonary infarction until proved otherwise. If the diagnosis of infarct is wrong no great harm is done; if the diagnosis is missed the consequence may be fatal. Cardiac pain may also simulate shoulder and cervical pain. . . . However, the differential diagnosis of cardiac pain and that from an orthopaedic condition is usually not difficult. In angina, a history of typical effort pain in the past preceding angina at rest can usually be obtained, and the sudden steady pain of a myocardial infarction is not likely to simulate orthopaedic disease.—J. S. Leland, M.D., Visceral Aspects of Shoulder Pain, *Bulletin of Hospital for Joint Diseases,* April, 1953.

ERYTHROMYCIN FOR INFECTIONS DUE TO MICROCOCCUS PYOGENES

Wallace E. Herrell, M.D., Donald R. Nichols, M.D.
and
William J. Martin, M.D., Rochester, Minn.

One of the most important current problems in the therapy of infectious disease is the management of infections due to strains of Micrococcus pyogenes (Staphylococcus aureus) that are resistant to many antibiotics. We have attempted to evaluate the effectiveness of erythromycin in the treatment of such infections. Although we have used erythromycin in a variety of infections due to organisms susceptible to its action, this report is concerned only with the results obtained with its use in M. pyogenes infection. In most of these cases the organisms were relatively insensitive to penicillin, streptomycin, aureomycin, and oxytetracycline (Terramycin).

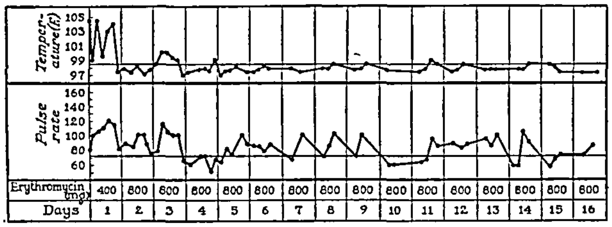
There are indications that in the constant changes that are occurring in the bacterial population many strains of M. pyogenes are naturally or have become resistant to penicillin, streptomycin, aureomycin, and oxytetracycline; for example, it was evident in a report from the Mayo Clinic by Needham and Nichols [1] that 60% of the strains of M. pyogenes that occur among hospital patients were penicillin resistant by 1948. The incidence of streptomycin-resistant strains was 41% during the same year. For a short time during the period that streptomycin was largely omitted in favor of other antibiotics, the incidence decreased slightly; however, it increased again when mixtures of penicillin and streptomycin came into more frequent use. It is evident in the same report that by November, 1951, the proportion of strains resistant to aureomycin and oxytetracycline had reached 36%. More recently, a similar survey [2] revealed that the proportion of strains of M. pyogenes resistant to aureomycin and oxytetracycline is 45%. To date, only rarely has a strain of M. pyogenes been found that is naturally resistant to erythromycin. The number of resistant strains may increase in the future, but, to date, erythromycin remains effective against the majority of such micro-organisms that are encountered.

It has been our practice to employ penicillin, combinations of penicillin and streptomycin, or the broad spectrum antibiotics in the treatment of staphylococcic infections when such infections were due to strains sensitive to these antibiotics. It is evident, however, that a large number of infections cannot be controlled with these agents or combinations of them, and in such cases erythromycin has proved of great value to date. The experience we have had with erythromycin in the treatment of 54 patients forms the basis for this report.

STAPHYLOCOCCIC SEPTICEMIA

The results obtained with erythromycin in staphylococcic septicemia are shown in table 1. Eight of the 54 patients treated had septicemia. There can be little doubt concerning the effectiveness of erythromycin in this type of infection, provided bacterial endocarditis has not developed. It is evident from the results of sensitivity tests given in the table that almost all of the organisms were resistant to penicillin, oxytetracycline, and aureomycin but were reasonably sensitive to erythromycin. It should be pointed out that these sensitivity tests represent inhibition and do not indicate the amounts of the antibiotics that would be required to obtain a bactericidal effect. Furthermore, it will be noted that in some instances the sensitivities shown were greater than 3.2 units per cubic centimeter for penicillin and in other instances greater than 10 units. This variation is due to the fact that during the course of the study the end point of the sensitivity test was changed from 3.2 to 10 units per cubic centimeter. These cases of septicemia are of sufficient interest to warrant a brief summary of each.

Case 1.—A 12-year-old boy had had poliomyelitis of the bulbar type with some paralysis of the upper extremities. To maintain fluid intake, exposure and cannulation of veins of the lower extremities had been necessary in preparation for intravenous feeding. Cellulitis developed, and a septic course followed. Blood cultures were positive for M. pyogenes. Treatment included multiple transfusions and administration of oxytetracycline, aureomycin, penicillin, chloramphenicol, and sulfisoxazole (Gantrisin). The illness had continued for four weeks before the patient was admitted to our hospital service. There were signs of early osteomyelitis in the right elbow. Results of the sensitivity tests done are shown in table 1. The patient's temperature and pulse rate curves are shown in the figure.



Clinical course of the patient in case 1 from the start of erythromycin therapy. Note the disappearance of fever within 48 hours.

Erythromycin was administered in the amounts indicated in table 1 for 15 days. Within 12 hours after this therapy had been started, the temperature was normal and, except for one episode of slight temperature elevation, the patient remained afebrile throughout the course of treatment. The pain and limitation of movement in the elbow promptly subsided, the cellulitis subsided, and the patient made a complete recovery.

Case 2.—A patient had undergone a transurethral operative procedure for removal of a neoplasm of the urinary bladder and had been dismissed from the hospital. The urine had contained M. pyogenes. Shortly after dismissal, extremely severe sepsis developed, and the patient was readmitted to the hospital with a temperature ranging between 104 and 105 F. Blood cultures showed M. pyogenes. The patient was critically ill and was unable to swallow. The organism was inhibited by 0.4 μg of erythromycin per cubic centimeter. The patient received erythromycin by the intravenous route and also by means of a nasal tube. Within 48 hours the organism became

---

From the Division of Medicine, Mayo Clinic.

A large portion of the erythromycin used in these studies was supplied by Eli Lilly & Company, Indianapolis, Abbott Laboratories, North Chicago, Ill., and the Upjohn Company, Kalamazoo, Mich.

[2] Needham, G. M.: Personal communication to the authors.

resistant to erythromycin, and despite intensive therapy with that antibiotic as well as with penicillin combined with streptomycin, the patient died.

CASE 3.—A patient had undergone mastoidectomy, and on the second postoperative day chills and fever developed. On one occasion, the temperature reached 105 F. The patient had been receiving penicillin and streptomycin. Blood cultures made during this therapy showed M. pyogenes, 20 colonies per cubic centimeter. Sensitivity studies showed that more than 10 units of penicillin per cubic centimeter and 0.78 µg of oxytetracycline and aureomycin per cubic centimeter were required to inhibit the organism. We decided to treat the patient with erythromycin, which inhibited the organism at a concentration of 0.4 µg per cubic centimeter. The amount given and the duration of treatment are shown in table 1. Blood cultures made 24 hours after treatment was begun were negative, and subsequnt cultures remained negative. The patient made an uneventful recovery.

CASE 4.—A patient had undergone transurethral resection for prostatic obstruction and urinary infection due to M. pyogenes. He had received penicillin in adequate dosage during the postoperative period, but chills and fever developed and he became extremely ill. Cultures of the urine and blood were positive for M. pyogenes. Results of sensitivity studies are shown in table 1. The patient received erythromycin by the oral route; within 48 hours after the start of treatment blood cultures became negative, and they remained so throughout his recovery.

7	73	P > 3.2 units C = 6.2 µg. T and A > 6.2 µg. E = 0.8 µg.	500	6	36	Organism resistant to all antibiotics except erythromycin. Complete recovery
8	48	P > 3.2 units T and A = 3.1 µg. E = 0.4 µg.	300	6	36	Initial response satisfactory. Blood cultures again became positive. Organism resistant to erythromycin. Therapeutic failure

* P, penicillin; S, streptomycin; E, erythromycin; T, oxytetracycline (Terramycin); A, aureomycin; C, chloramphenicol.
† Administered by intravenous route.

CASE 5.—A patient with a bullous type of dermatitis had fever and had not responded to treatment with oxytetracycline and sulfonamides. On one occasion, his temperature rose to 104 F, at which time blood cultures were positive for M. pyogenes. He was given erythromycin orally, the blood cultures became negative, and he recovered from the septicemia.

CASE 6.—A man, 77 years old, was admitted to the hospital because of a fractured tibia. Urinary obstruction developed, for which catheterization was required. The patient also had urinary infection due to M. pyogenes. After catheterization, the patient became critically ill. Blood and urine cultures were both positive for M. pyogenes. The organism was resistant to penicillin, oxytetracycline, and aureomycin but was sensitive to erythromycin. The patient received 50 doses of erythromycin by the oral route. He made a satisfactory recovery from the septicemia, and the organism was eliminated from the urine. He later underwent transurethral resection, and four or five weeks after the original infection had disappeared, septicemia due to M. pyogenes again developed. The organism was still resistant to the antibiotics mentioned and was sensitive to erythromycin. A second course of 83 doses of erythromycin was given by mouth, and complete recovery occurred. It is interesting to speculate on whether this patient had a recurrence or a reinfection, but, regardless of which was the case, erythromycin was effective in eliminating M. pyogenes from the blood and urine on two separate occasions.

CASE 7.—Sepsis developed in a patient in the period following a transurethral operative procedure. He had received penicillin, sulfisoxazole, and aureomycin, without improvement. Blood cultures revealed M. pyogenes, which was resistant to penicillin, chloramphenicol, oxytetracycline, and aureomycin but was sensitive to erythromycin. The patient received erythromycin orally and made a complete recovery.

CASE 8.—A patient was admitted to the hospital with fever of unknown origin. Blood cultures revealed M. pyogenes. The patient had been treated previously for this illness with penicillin, aureomycin, and oxytetracycline. During such treatment she had, on occasion, been symptomatically improved. A heart murmur was heard, and a presumptive diagnosis of bacterial endocarditis was made. The organism isolated from her blood at the time erythromycin therapy was begun was resistant to penicillin, oxytetracycline, and aureomycin. It was inhibited by 0.4 µg of erythromycin per cubic centimeter of blood. Erythromycin was given orally, and the initial response was satisfactory, but during treatment blood cultures again became positive. The organism at this time was found to be completely resistant to erythromycin, and the patient died from bacterial endocarditis.

There can be little doubt that erythromycin therapy proved lifesaving in six of these eight cases. It was evident in one of the early reports on erythromycin from the Mayo Clinic [3] that bacteria could be made resistant to erythromycin in vitro but that considerable time was required and the development of resistance was comparatively slow. In the two cases reported in which failure occurred (cases 2 and 8), it is apparent that the bacteria became resistant in vivo with extreme rapidity and that this rapid reversal of sensitivity to erythromycin is similar to that that has been seen to occur with streptomycin. Since bacteria at times appear to become rather rapidly resistant to erythromycin and since bactericidal levels of erythromycin in the serum of patients are not easily attainable with the doses usually employed, we would not recommend the routine use of erythromycin in the treatment of bacterial endocarditis due to M. pyogenes.

---

[3] Heilman, F. R.; Herrell, W. E.; Wellman, W. E., and Geraci, J. E.: Some Laboratory and Clinical Observations on a New Antibiotic, Erythromycin (Ilotycin), Proc. Staff Meet., Mayo Clin. 27: 285-304 (July 16) 1952.

A satisfactory or excellent clinical result was obtained in eight cases (about 50%), and a doubtful result or failure occurred in nine. Although failure in a few instances was due to the fact that the organism became resistant to erythromycin, not all of the failures could be explained on this basis. In several instances the organism remained sensitive to erythromycin throughout the course of treatment, which in some instances was prolonged, yet it was never completely eliminated from the wound. This may be due to the fact that, because of the type of infection present, adequate amounts of the antibiotic could not reach the infected surface. It would appear, however, that erythromycin has a place in the treatment of some skeletal and soft tissue infections due to sensitive strains of M. pyogenes in which other antibiotics are relatively ineffective. Despite prolonged treatment in a number of these cases, no serious toxic effects were noted that could be attributed to the use of erythromycin.

Table 2.—*Results of Erythromycin Therapy in Infections of Skeletal System and Soft Tissues Due to M. Pyogenes*

					Dose of Erythromycin			
Case	Age, Yr.	Diagnosis	Source of Culture	Antibiotic Sensitivity, Per Cc.*	Mg.	Interval, Hr.	Total No. of Doses	Results and Remarks

INFECTIONS OF THE SKELETAL SYSTEM AND SOFT TISSUES

In 17 of the 54 cases included in this report erythromycin was used in the treatment of infections of the skeletal system and soft tissues due to M. pyogenes. In most instances the organism was found to be resistant to the other currently available antibiotics but was reasonably sensitive to erythromycin. The source of culture in these cases, antibiotic sensitivities, doses used, duration of treatment, and results obtained are shown in table 2.

STAPHYLOCOCCIC ILEOCOLITIS

The occurrence of fatal staphylococcic enteritis following the oral use of streptomycin was described in 1948 by Kramer.[4] Zischka [5] has reported that this may also occur following the oral use of sulfaguanidine. Recently, Dearing and Heilman [6] reported the occurrence of ileocolitis owing to the growth of resistant strains of M. pyogenes in the intestinal tract of patients who had received aureomycin or oxytetracycline for preoperative preparation of the bowel. We have treated 14 patients with a condition diagnosed as staphylococcic ileocolitis. Although it is true that in the majority of these patients this condition occurred during aureomycin or oxytetracycline administration for preoperative preparation, it should be emphasized that it can occur in patients hospitalized for other reasons who have not received the broad spectrum antibiotics; for example, 3 (those in cases 31, 35, and 38, table 3) of our 14 hospitalized patients had not received aureomycin or oxytetracycline. A fourth (the patient in case 39, table 3) had not received any antibiotic by the oral route, but staphylococcic ileocolitis developed in him while oxytetracycline was being administered intravenously and streptomycin intramuscularly for septicemia due to a gram-negative organism.

There can be no doubt that a large number of persons among hospital personnel normally harbor strains of M. pyogenes that are resistant to the broad spectrum antibiotics. It is possible that patients admitted to the hospital may acquire these organisms in their throat or nasal passages by contact or through food and that the organism may thereby gain entrance into the intestinal tract. At any rate, persons with or without ileocolitis may harbor resistant strains of M. pyogenes in their stools for reasons other than the fact that they have received broad spectrum antibiotics. The ileocolitis that occurs in the immediate postoperative period is sometimes very severe, and the causative mechanism is not entirely understood. It seems reasonable to assume that the stress of a major surgical procedure, with the probable release of large amounts of adrenocortical hormones, may in some way increase the susceptibility of the patients to invasion by Micrococcus organisms.

Although it is true that this form of ileocolitis may at times be severe, it should rarely, if ever, be fatal if proper treatment is given. Its management is relatively simple, but the possibility of its occurrence must be kept in mind. Smears of stools and cultures should be obtained for any hospitalized patient with signs of ileocolitis, regardless of whether he is being given broad spectrum antibiotics. To date, all the strains encountered in our hospital have been sensitive to erythromycin. If such a patient is receiving broad spectrum antibiotics, their administration is immediately discontinued, and the patient is given erythromycin orally. Within 24 to 72 hours clin-

TABLE 3.—*Results of Erythromycin Therapy in Ileocolitis Due to M. Pyogenes*

Case	Age, Yr.	Culture Source	Antibiotic Sensitivity, Per Cc.*	Dose of Erythromycin			Results and Remarks
				Mg.	Interval, Hr.	Total No. of Doses	
26	45	Stool	P = 0.5 unit T and A > 6.2 µg. E = 0.4 µg.	300	6	32	Diarrhea under control in 24 hr. Recovery
27	56	Stool	Not done	400	6	27	Stool revealed usual flora in 72 hr. Recovery
28	52	Bowel mucosa swab	P > 10 units T and A > 6.2 µg. E = 0.8 µg.	400	6	26	Patient very ill. Complete recovery
29	59	Stool	P > 10 units T and A > 6.2 µg. E = 0.8 µg.	300	6	24	Stool cultures showed return to usual flora. Recovery
30	44	Stool	Not done	400	6	19	Prompt control of fever and diarrhea. Recovery
31	32	Stool	P > 10 units T and A > 6.2 µg. E = 0.4 µg.	400	6	20	Diarrhea subsided in 24 hr. Stool showed return to usual flora. Recovery. Did not receive broad spectrum antibiotics
32	56	Stool and wound	P > 10 units T and A > 6.2 µg. E = 0.8 µg.	300	6	39	Stool showed return to usual flora. Recovery
33	76	Stool and sputum	P > 10 units T and A > 6.2 µg. E = 0.8 µg.	300	6	72	Prompt control of symptoms. Recovery
34	50	Stool and wound	T and A > 6.2 µg. E = 0.2 µg.	300	6	34	M. pyogenes eliminated from stools and abdominal drainage material. Complete recovery
35	63	Stool Urine	P > 0.1 unit T and A = 0.78 µg. E = 0.8 µg. E = 0.4 µg.	300	6	16	Staphylococcic colitis developed in hospital without exposure to broad spectrum antibiotics. Recovery
36	18	Stool	P > 10 units T and A > 6.2 µg. E = 0.8 µg.	300	6	10	Diarrhea subsided. Complete recovery
37	45	Stool	P > 10 units T and A = 0.39 µg. E = 0.4 µg.	400	6	26	Complete recovery
38	66	Stool and bowel mucosa swab	P > 10 units T and A > 6.2 µg. E = 1.6 µg.	400	6	15	Colitis developed in hospital without exposure to broad spectrum antibiotics. Complete and satisfactory response to erythromycin therapy
39	55	Stool	P > 10 units T and A > 6.2 µg. E = 0.4 µg.	300	6	32	Was receiving oxytetracycline intravenously and streptomycin intramuscularly. Colitis developed. Prompt response to erythromycin therapy

* P, penicillin; T, oxytetracycline (Terramycin); A, aureomycin; E, erythromycin.

ical improvement occurs, and a return to the usual flora is found on stool cultures. In our 14 cases oral administration of erythromycin in the doses indicated in table 3 resulted in complete recovery of all the patients. Similar results are expected in the future, provided erythromycin-resistant strains are not encountered.

MICROCOCCI IN COLON CONTENT WITHOUT SYMPTOMS OF INFECTION

It was previously pointed out that patients may harbor M. pyogenes in their colon content without having symptoms of infection. We have had five such patients (table 4). All of these patients had received one of the the broad spectrum antibiotics in preparation for an operation. Routine cultures of material obtained by swabbing the bowel mucosa or cultures of the stool revealed the presence of M. pyogenes. Sensitivity studies were done for only two of the five patients, but in both the organisms were of the type usually seen in such cases. The organisms were not inhibited by 10 units of penicillin per cubic centimeter or by 6.2 μg of oxytetracycline or aureomycin per cubic centimeter. They were sensitive to erythromycin. In all five patients oral administration of 300 or 400 mg. of erythromycin every six hours promptly eliminated M. pyogenes from the stools.

MISCELLANEOUS STAPHYLOCOCCIC INFECTIONS

Ten of our 54 cases were classed as miscellaneous infections. The diagnosis, source of the culture, and other pertinent data are summarized in table 5. There was one example (case 45) of meningitis due to a strain of M. pyogenes that was relatively resistant to penicillin and the broad spectrum antibiotics but that was sensitive to erythromycin. There were two examples (cases 46 and 49) of infections in the urinary tract due to resistant strains of M. pyogenes. The use of erythromycin by the oral route resulted in elimination of this organism from the urine. There were five instances in which a resistant strain of M. pyogenes was found in the nose or throat of persons with acute infections of the nose or throat. In four of these the organism was promptly eliminated and clinical improvement occurred; the fifth improved clinically, but a few micro-organisms were still present in the throat when treatment was discontinued.

Table 4.—*Results of Erythromycin Therapy for M. Pyogenes in Colon Content Without Occurrence of Symptoms*

				Dose of Erythromycin			
Case	Age, Yr.	Culture Source	Antibiotic Sensitivity, Per Cc.*	Mg.	Interval, Hr.	Total No. of Doses	Results and Remarks
40	71	Bowel mucosa swab	Not done	400	6	16	Stool showed prompt return to usual flora, with elimination of M. pyogenes
41	66	Bowel mucosa swab	P > 10 units T and A > 6.2 μg. E = 0.8 μg.	300	6	14	M. pyogenes eliminated from stool
42	31	Stool	Not done	300	6	35	M. pyogenes eliminated from stool
43	55	Stool	Not done	300	6	14	Stool showed return to usual flora, with elimination of M. pyogenes. Later died from metastatic carcinoma
44	56	Bowel mucosa swab	P > 10 units T and A > 6.2 μg. E = 0.8 μg.	400	6	24	Stool showed return to usual flora, with elimination of M. pyogenes

Table 5.—*Results of Erythromycin Therapy in Miscellaneous Infections Due to M. Pyogenes*

					Dose of Erythromycin			
Case	Age, Yr.	Diagnosis	Culture Source	Antibiotic Sensitivity, Per Cc.*	Mg.	Interval, Hr.	Total No. of Doses	Results and Remarks
45	66	Meningitis	Spinal fluid	P > 3.2 units T and A = 3.1 μg.	400 500	6 6	31 35	Striking response. Complete recovery
46	78	Urinary infection	Urine	P > 10 units T and A > 6.2 μg. E < 0.2 μg.	300 400	6 6	4 21	M. pyogenes eliminated from urine
47	42	Throat infection	Throat	P > 10 units T and A > 6.2 μg. E = 0.4 μg.	300	6	15	M. pyogenes eliminated from throat and stool
48	5 mo.	Collapsible trachea	Trachea	P > 10 units T and A > 6.2 μg. E = 0.4 μg.	50	12	18	Temperature promptly subsided. M. pyogenes eliminated from sputum
49	51	Urinary infection	Urine	Not done	300	6	20	Urinary infection promptly cleared
50	17 mo.	Cystic disease of pancreas with pneumonitis	Throat	P > 3.2 units T and A > 6.2 μg. E = 0.4 μg.	50	6	65	M. pyogenes eliminated from throat, but died of primary disease
51	17	Pharyngitis	Throat	P > 3.2 units T and A > 6.2 μg. E = 0.8 μg.	375	6	17	M. pyogenes disappeared from throat cultures. Infection cleared
52	43	Purulent rhinitis	Nose	P > 3.2 units A > 6.2 μg. C = 3.1 μg. E = 0.2 μg.	300	6	28	Prompt clinical response. Cultures became negative
53	67	Postoperative empyema	Pleural fluid	P > 10 units T and A > 6.2 μg. E = 0.4 μg.	300	6	16	Excellent response to treatment
54	18	Acute septic tonsillitis	Throat	P = 10 units T and A = 0.78 μg. E = 0.8 μg.	300	6	19	Clinical improvement, but a few organisms still present when treatment discontinued

* P, penicillin; T, oxytetracycline (Terramycin); A, aureomycin; E, erythromycin; C, chloramphenicol.

In a case of postoperative empyema due to a M. pyogenes erythromycin appeared to be effective. The organism was resistant to penicillin, oxytetracycline, and aureomycin but was sensitive to erythromycin. M. pyogenes was isolated from the trachea of a child with a collapsible trachea and pneumonitis. The organism was resistant to penicillin, oxytetracycline, and aureomycin but was sensitive to erythromycin. It was eliminated from the tracheal secretions after treatment with erythromycin.

DOSAGE AND METHODS OF ADMINISTRATION

For the average adult patient, the oral dose of erythromycin that we give is 300 to 400 mg. every six hours. This represents a daily dose of 20 to 25 mg. per kilogram of body weight. Doses in excess of 400 mg. every six hours given orally may cause gastrointestinal irritation, which takes the form of nausea, rarely vomiting, and occasionally loose stools. Preparations of the drug now are available for intravenous administration. This form of therapy is used only in persons who for any reason cannot take the preparation orally. The average adult dose for intravenous administration is 250 mg. dissolved in the buffer solution and given every six or eight hours. The intravenous route should not be used for patients with ileocolitis. If for any reason a patient cannot swallow, the erythromycin can be introduced into the intestinal tract through a gastric tube.

SUMMARY AND CONCLUSIONS

Many strains of Micrococcus pyogenes (Staphylococcus aureus) are naturally or have become resistant to penicillin, streptomycin, aureomycin, and oxytetracycline (Terramycin). In infections due to these resistant strains we have employed erythromycin in an attempt to evaluate the effectiveness of this antibiotic in the treatment of such infections. To date, only rarely has a strain of M. pyogenes been found to be naturally resistant to erythromycin. Only further experience will determine to what degree M. pyogenes may develop resistance to this antibiotic. We have used erythromycin in the treatment of 54 patients with various types of infections due to strains of M. pyogenes that were found to be resistant to the more commonly employed antibiotics.

Erythromycin proved highly effective and in some instances lifesaving in the treatment of six of eight patients with staphylococcic septicemia. In the two cases in which this treatment failed the organism rapidly became resistant to the antibiotic in vivo, and the patients died from bacterial endocarditis. Satisfactory clinical response followed the use of erythromycin in infections of the skeletal system and soft tissues in about half of 17 cases. In some failure was attributable to the development of resistance, but in others failure resulted for other reasons. Erythromycin was successfully used in 14 cases of staphylococcic ileocolitis, and it was effective in eliminating M. pyogenes from the stools of 5 patients who harbored the organism in their intestinal tracts but who had no symptoms. Erythromycin was effective in a variety of miscellaneous infections due to M. pyogenes, including meningitis and throat and urinary tract infections. To date, no serious toxic reactions have been encountered after the use of erythromycin in the amounts employed in this series.

Erythromycin appears to be an effective antibiotic in the treatment of a number of infections due to M. pyogenes. Its widespread routine or indiscriminate use may in time result in the appearance of more resistant strains, but the extent to which this will occur is, at present, a matter for speculation.

GRANULOMA FOLLOWING SWIMMING POOL ABRASION

Rees B. Rees, M.D.
and
James H. Bennett, M.D., San Francisco

Hellerström, of Stockholm, first mentioned the possibility of cutaneous tuberculosis developing in abrasions from public swimming pools. He described six facial lesions, five of which followed abrasions sustained in the same pool.[1] Water and sediment from the pool involved in the sixth case produced tuberculosis in a guinea pig. With material from the infected animal, tubercle bacilli were grown on a special medium. Hellerström's patients were males, aged 14 to 29 years, with no history of tuberculosis. In five pulmonary findings were normal, and in the sixth there were small hilar calcifications. In five the tuberculin reaction was negative before and positive after the injury. The clinical picture was strikingly uniform, with soft reddish-brown papules, pinhead to split pea in size and crusted and coalescent. The initial swimming pool abrasions became covered with epithelium but gave rise to granulomas without a period of perfect healing. Diascopy showed lupus vulgaris nodules. The regional lymph nodes were not enlarged or only slightly so. The lesions appeared three to six weeks after the injury. Histological features were compatible with, but not diagnostic of, lupus vulgaris. There were collections of epithelioid cells, and all but one lesion showed giant cells of the Langhan type. Acid-fast bacilli were found in one case, and these were few. Cultures and guinea pig inoculations yielded no organisms. Treatment included ultraviolet light baths, Finsen lamp exposures, calciferol by mouth, and (in one case) *p*-aminosalicylic acid. These lesions healed in three to nine months.

Hellerström believed that a high degree of allergy developed rapidly in these nontuberculous persons because

Case 7 was contributed by Dr. Normal Epstein, case 8 by Dr. Patrick Butler, and case 9 by Dr. Melvin Black. Dr. Ellis Sox, Director of Public Health in San Francisco, cooperated in this study.

[1] Hellerström, S.: Collected Cases of Inoculation Lupus Vulgaris, Acta dermat.-venereol. 31: 194-211, 1951.

of the superficial nature of the inoculation, avoiding the traditionally violent primary tuberculous complex of the skin, with ulceration, destruction, and regional lymph node involvement. Lupus vulgaris occurs in persons possessing some degree of allergy or immunity to the tubercle bacillus. The absence or scarcity of tubercle bacilli suggests the importance of an immunobiological factor.

Sulzberger and Baer,[2] in commenting on Hellerström's report, described the case of a young man in New York in whom small groups of lupus vulgaris nodules developed on the bridge of his nose. Hellerström had seen the patient and elicited a history of an abrasion on the nose incurred in a dive into a swimming pool. Tolmach and Frank,[3] in an intensive study, found no tubercle bacilli or silica.

Cleveland,[4] of Vancouver, reported four cases of possible primary tuberculous infections of the skin, which complicated abrasions produced in a public swimming pool. Clinical and histological evidence suggested tuberculosis of the skin in each, although no acid-fast bacilli were found. Two of his patients had negative results in tuberculin tests, and two were not tested. Histological examination showed tuberculoid changes in three lesions, but the fourth patient had only a diffuse granulomatous structure, with abundant lymphocytes and giant cells. These lesions responded to roentgen therapy within three to five months, although destruction with solid carbon dioxide was necessary for residual lesions in one case. Williams found four more cases from the same pool. Cleveland has an open mind regarding etiology, in view of the lack of definite proof that the lesions were due to local inoculation with tubercle bacilli.[5]

Shaw [6] saw 10 or 12 patients with granulomatous lesions on the knee, elbow, or nose, all of whom sustained abrasions in a swimming pool in Seattle. He concluded that the lesions were not tuberculous because there was no laboratory proof and because they all healed within a few months. Sulzberger and Baer [2] believe that this condition should be recognized as a syndrome. There is considerable difference of opinion regarding etiology. Baer has pointed out the possibility of smegma bacilli (which resemble tubercle bacilli) being present in swimming pools in large numbers and causing tuberculoid structures. Szymanski inoculated eight persons with smegma bacilli. In three lesions developed that had a tuberculoid architecture 14 to 30 days afterwards.

Tolmach [3] suggested that silicates used as purifiers in swimming pools might cause granulomas. More recently Brück [7] reported inoculation lupus in a man, aged 23 years, that developed after a swimming pool abrasion. Tubercle bacilli of the human type were cultured from the lesion and subsequently produced tuberculosis in guinea pigs. Brück believes that two different types of infections may result from swimming pool injuries: inoculation lupus vulgaris and so-called mycobacteriosis balnearea, as reported by Nordén and Linell [8] and Zettergren.[9] Nordén and Linell concluded that in the more than 80 cases (first observed by Herlitz [10] in Örebro, Sweden) Koch's bacillus was not responsible. They believed that the infections were due to a type of Mycobacterium that was different biologically from Myco. tuberculosis. In practically every one of the Örebro cases the elbow was the site of injury. The lesion commenced as a papule that ulcerated and then healed spontaneously after 6 to 24 months. Nordén and Linell succeeded in demonstrating Myobacterium micro-organisms not only in the ulcers but in the water and on the walls of the pool. Cement from the pool wall rubbed into the skin of a rabbit produced tissue changes similar to those in the human lesions. In some preparations, a tuberculoid structure was observed, sometimes with central fibrinoid necrosis. Staining by the Gram and Ziehl-Neelsen methods revealed no organisms. In cultures, however, there were acid-fast organisms indistinguishable from tubercle bacilli. Guinea pig inoculations were nonproductive, but intraperitoneal injections into mice resulted in ulcerations along the tail and swellings and ulcerations of the feet that were filled with acid-fast bacilli.

Zettergren observed six skin lesions following swimming pool injuries. They were similar clinically to those described by Nordén and Linell. Attempts at demonstrating tubercle bacilli were unsuccessful. Zettergren felt that the causative agent was probably Myco. marinum, or a closely related species. It should be emphasized that the lesions reported by Hellerström were clinically those of lupus vulgaris and that they occurred on the nose. In Nordén and Linell's cases, and in Zettergren's, the lesions were on the elbow and were ulcerated. Hellerström [11] now believes, with Brück, that there are two types of swimming pool infections. One is inoculation lupus, and the other is the ulcerative type of lesion on the elbow, presumably caused by Myco. marinum.

The question of silica granuloma deserves special attention. This possibility must be ruled out in postabrasion skin granulomas generally.[12] These lesions were originally described by Shattuck in 1916, and the literature up to March, 1950, plus further case studies have been reviewed by Sommerville and Milne.[13] These lesions are reddish, rather soft papules or tumors that clinically are suggestive of cutaneous sarcoidosis. They may follow abrasions, especially those acquired on sandy walks or roads or from sandblasting, but their appearance usually is delayed for months or years after injury. Histologically, there is a sarcoid-like reaction with clusters of epithelioid cells, giant cells, and perhaps even amorphous crystalline particles in routinely stained sections. Under polarized light, however, one sees angular colorless particles of silica (silicon dioxide), which are highly refractile. Silicon is a dark gray, opaque, and needle-like crystalline material; at times it may have octahedral platelets. It does not occur free in nature; it is found as silica (quartz and sandstone) or as silicates (feldspar [orthoclase, kaolinite, or anorthite]). Evans[15] pointed out that silica is a "fibrosive" material and that Carborundum is not. Mica is a symmetrical silicate known to be benign in tissues. The pathogenesis of silica granuloma is very much like that of silicosis of the lungs.

REPORT OF CASES

Nine cases in which a clinical diagnosis of tuberculosis verrucosa cutis was made are herein reported. The same pool was used by all patients except the one in case 6. In all cases except cases 7 and 8 examination of serial tissue sections stained by the Ziehl-Neelsen and Hotchkiss McManus techniques, and under the polariscope showed no tubercle bacilli, deep fungi, or silica. When roentgen therapy was given, the factors were 76 kv., 5 ma., 8 in. target-skin distance, no filtration, half-value layer, 0.75 mm. Al.

Case 1.—A 20-year-old man abraded his left knee in 1950. The abrasion healed over but became warty and granulomatous. A tuberculin patch test in August, 1952, gave positive results. Histological changes were nonspecific, with small round cell masses. The lesion was given 600 r in divided doses. Response was slow. On Oct. 27, 1952, isoniazid in a dose of 150 mg. daily by mouth was prescribed (his weight was 130 lb. [59 kg.]). After nine days the lesion healed. The patient then struck the knee while doing acrobatic dancing, and one small granulomatous papule reappeared. He was again treated with isoniazid, and the lesion healed.

Case 2.—A 13-year-old schoolgirl abraded both knees in March, 1951. When she was seen six or seven months after the injury, there was a warty, granulomatous, reddish, superficially scaling lesion on the left knee, 3 by 3 cm. in diameter. A tuberculin patch test gave no reaction after 48 hours. Histological examination showed pseudoepitheliomatous hyperplasia, rather sparse collections of small round cells, some tubercle formation, but no giant cells. The patient was given 975 r in divided doses and 100,000 units of calciferol by mouth in two separate courses of a month each, without response. On Nov. 6, 1952, she began taking isoniazid, 150 mg. daily by mouth, which promptly healed the lesion. One small area recurred two months later and was removed electrosurgically.

Case 3.—An 11-year-old schoolboy abraded his left knee. When he was seen four months later there was a 3 by 3 cm. granulomatous, dusky red and scaly lesion. A tuberculin patch test was positive. Histological examination showed pseudoepitheliomatous hyperplasia, dense collections of small round and epithelioid cells, no definite tubercle formation, no giant cells, and no caseation necrosis. A roentgenogram of the chest showed no evidence of tuberculosis. The lesion was given 775 r in divided doses, but it did not respond. Isoniazid, 150 mg. daily for one month, was not helpful.

Case 4.—An 8-year-old schoolgirl abraded her left knee in the summer of 1951. The abrasion never healed entirely, and thickened, dark reddish scaly lesions developed at the site. Tuberculin test was negative five years before and negative six months after the injury. In September, 1951, she was found to have three separate granulomatous lesions, one of them 2 by 2 cm. in size and the others 0.5 cm. in diameter. Histological examination showed a nonspecific granuloma without definite tubercle or giant cell formation. The lesions were given 1,250 r in divided doses. They healed within six months. The patient also took 100,000 units of calciferol daily by mouth for one month.

Case 5.—An 8-year-old schoolboy abraded his left knee on a schoolground in the summer of 1951 and, while the lesion was still denuded, went swimming. The denuded area failed to heal entirely, giving rise to warty, granulomatous and scaly papules 2 by 2 cm. in diameter. A tuberculin patch test performed in May, 1952, gave a positive reaction. Histological examinations showed pseudoepitheliomatous hyperplasia, many small round cells in dense clusters, interspersed with some polymorphonuclear leukocytes, collections of epithelioid cells to form large tubercles, and numerous giant cells. The lesion was given 750 r in divided doses and healed entirely within five months.

Case 6.—A 17-year-old schoolboy abraded his left knee during the summer of 1951. The abrasion became covered with epithelium but immediately gave rise to granulomatous, dusky red, scaly lesions in an area 3 by 3 cm. in size. Histological examination showed pseudoepitheliomatous hyperplasia, small round cells, and epithelioid cells that formed tubercles; there were a number of Langhan's giant cells. A tuberculin patch test was positive. The lesion healed, with the exception of one papule 1 cm. in diameter, after the administration of 550 r in divided doses. For the residual lesion, isoniazid was prescribed in a dose of 150 mg. daily by mouth. The final outcome is not yet known.

Case 7.—A 13-year-old schoolboy was seen on Jan. 11, 1952, with a reddened, warty and scaly growth, 1.3 by 1.3 cm. in size, over the knuckle of his right index finger, of seven months' duration. He had scratched the area on the side of a public swimming pool. An intradermal tuberculin test gave a strong reaction. Roentgenographic examination of the lungs on Feb. 13, 1952, showed a small area of increased density at the right base and probable mediastinal adenopathy. Histological examination showed tremendously thickened epidermis and a small acute ulceration superficially. Deeper, there was a granulomatous inflammatory reaction with distinct small tubercles, many Langhan's giant cells, and a suggestion of caseation. Acid fuchsin stains did not reveal organisms, and the lesions did not suggest sarcoid. There were no foreign body particles. He was given streptomycin by injection and *p*-aminosalicylic acid by mouth. The lesion shrank somewhat but was still present on Dec. 31, 1952. It was then excised, and biopsy material was injected intraperitoneally into two mice. No abnormalities resulted.

Case 8.—A 16-year-old schoolgirl abraded the front of her right ankle in October, 1951. This abrasion failed to heal entirely. A papular, reddish, crusted lesion 1.5 by 2 cm. developed. With crust removed, the surface was warty and granular. "Apple jelly" nodules were not evident on diascopic pressure. Direct microscopic examination of scales from the lesion, using potassium hydroxide, showed no evidence of fungus infection. Biopsy showed moderate hyperkeratosis and parakeratosis covering a marked acanthosis and spongiosis. Papillary capillaries were dilated and surrounded by dense lymphocytic infiltration. In one capillary body there was a group of epithelioid cells, surrounded by an intense zone of lymphocytic infiltration. At one end of the section there were numerous abscesses of polymorphonuclear leukocytes. Acid fuchsin stain showed no tubercle bacilli. The histological picture was compatible with tuberculosis verrucosa cutis. An intradermal tuberculin test gave a positive reaction on Feb. 23, 1952. Roentgen examination of the chest showed no abnormalities. In March, 1952, the lesion was destroyed by electrosurgery. Formation of a thick scar followed, but the scar responded to roentgen therapy.

Case 9.—A 20-year-old man abraded his left knee in a San Francisco pool in December, 1951. A 7 by 3 cm. granulomatous plaque developed and persisted. Erythema nodosum developed on both legs. This, however, cleared spontaneously after a number of weeks. A chest roentgenogram showed no evidence of tuberculosis. Results of tuberculin tests are not known. Histologically there were groups of closely packed tubercles and macrophages accompanied by multinucleated giant cells of the Langhan's type, with surrounding collars of

lymphocytes, plasma cells, and histiocytes. Acid-fast bacilli and fungi were not demonstrated by special strains; cultures presented no growth. Adjacent to the markedly granulomatous process there was much scarring with perifollicular and periglandular fibrosis with deposition of brown pigment, which took the stain for iron. Dr. Black raised the question of a granulomatous reaction to some constituent of the tile or grout in the swimming pool and suggested the advisability of chemical analyses of these materials and perhaps experiments with animals to determine if some chemical like beryllium were present. The entire lesion was excised on Feb. 13, 1953.

No history of tuberculosis was given in any of the cases, and tuberculin tests were performed prior to the injury only in cases 4 and 8. In case 4 a test done four years previously was negative. In case 8 there were prior positive tuberculin tests but no findings of tuberculosis and no family history of it. A pulmonic density in case 7 was the only evidence of pulmonary tuberculosis. Guinea pig inoculation was negative in cases 1, 2, 3, and 7 and was not done in the other cases.

Two additional patients with lesions that were clinically diagnosed as tuberculosis verrucosa cutis and that did not follow swimming pool abrasions were studied, but no tubercle bacilli, deep fungi, or silica were found. Guinea pigs were inoculated in these two cases.

COMMENT

The lesions in these patients differ sharply in one respect from those found in the patients of Hellerström, Cleveland, Brück, and others. They were typical clinically of tuberculosis verrucosa cutis, whereas previously reported lesions were of the lupus vulgaris type. Lupus vulgaris is a rarity in California. Hellerström stresses the fact that his cases were not those or ordinary lupus vulgaris but seemed to be the result of superficial inoculation of the skin with the tubercle bacillus, bypassing a violent primary tuberculous complex of the skin. He assumed that these lesions pass through a fleeting phase of a primary complex and rapidly develop typical nodules of lupus vulgaris. The very superficial nature of the inoculation presumably allowed this sequence of events to occur. Our patients belonged to the age group (8-20 years) in which one would not expect to see the reinoculation type of tuberculosis of the skin, such as verruca necrogenica or tuberculosis verrucosa cutis. There is no way of showing that these lesions are not the reinoculation type of tuberculosis, and yet, if Hellerström's thesis is correct, it is possible that the superficial nature of the inoculation may have produced some degree of resistance within the host, without the development of a primary complex, and may have given rise to a reinoculation type of cutaneous tuberculosis that is more commonly seen in California, namely, tuberculosis verrucosa cutis.

Attempts were made to establish an etiological diagnosis. No tubercle bacilli were found in any of the histological specimens, in spite of examination of serial sections stained with acid fuchsin. In four patients whose lesions were biopsied for guinea pig inoculation, no evidence of tuberculous infection was found. Sulzberger and Goodman [16] have shown that it may be very difficult to demonstrate tubercle bacilli in clinically typical lesions of cutaneous tuberculosis. Deep fungus infections, notably blastomycosis, were ruled out by examination of serial sections stained with the Hotchkiss McManus technique. Silica granuloma or a granuloma from silicates used as purifiers in swimming pools has been eliminated by examination of serial sections under the polariscope. In addition, the clinical history and course is radically different in silica granuloma. The suggestion by Sulzberger and Baer that these lesions might be the result of inoculation with smegma bacilli, which resemble tubercle bacilli, has not been proved or disproved. The possibility that smegma bacilli may be present in swimming pool water and/or sediment cannot be denied. Szymanski has produced tuberculoid lesions by inoculating smegma bacilli into the skin. The response to treatment is somewhat suggestive in regard to etiology. The fact that the lesions responded rather rapidly, although incompletely, in two patients treated with isoniazid is suggestive of a tuberculous nature.[17] It is known that both tuberculosis verrucosa cutis and verruca necrogenica may heal spontaneously. Our patients' lesions tended to heal within a period of six months, under the influence of x-ray therapy, calciferol by mouth, or isoniazid.

Valuable indirect evidence as to etiology would result if tubercle bacilli could be cultured, using the water or sediment from the public pool frequented by most of these patients. The San Francisco Department of Public Health has done such studies, without recovering organisms. It is apparent from the reports of Hellerström and others that viable tubercle bacilli can be found in public plunges. It has been shown that resurfacing the pools with smooth tile and raising the chlorine content will eliminate the incidence of these lesions. Cleveland has suggested that swimming pools might be a source of more serious tuberculous infection if they are capable of producing lesions of the type mentioned in this study. This cannot be denied. On the basis of clinical experience, however, it would appear that, in lesions resulting from swimming pool abrasions, changes are benign and somewhat self-limited in nature. Furthermore, they are relatively uncommon. Twenty-six to 28 cases have been recognized on the North American continent.

SUMMARY

Attention is drawn to the possibility of tuberculous infections following abrasions in swimming pools by Hellerström of Sweden. He presented the first case of "swimmers' lupus" in 1932. In 1951 he reported six such cases.

This study includes seven children and two young adults. Six of these persons had clinical tuberculosis verrucosa cutis on the left knee following abrasions sustained in swimming pools. The site of injury in the seventh case was the right index finger and in the eighth, the front of an ankle. Eight patients had been in the same pool. Tubercle bacilli were not found, although serial sections were examined. Most of the patients had positive tuberculin tests following the injuries. Silica granuloma was ruled out by examination of serial sections with the polariscope and deep mycotic infections by Hotchkiss McManus stains. Guinea pig inoculations in four cases failed to demonstrate tubercle bacilli. Most lesions responded within three to six months, either with conservative roentgen therapy, calciferol, or, in two resistant cases, with isoniazid, which promptly cleared the lesions.

[17] Chemotherapy and Intracellular Tubercle Bacilli, editorial, J. A. M. A. 151: 47 (Jan. 3) 1953.

No causative agent was demonstrable in any of these cases. There is a need for emphasizing the existence of the problem. It is of public health importance. As suggested by Sulzberger and Baer, it may represent a syndrome. Some agent other than all the possible ones mentioned by various authors may be at fault. It need not necessarily be microbial in nature. The response to isoniazid may not necessarily signify a tuberculous etiology. The most useful suggestion in regard to elimination of the problem appears to be that of Hellerström, namely, the resurfacing of swimming pools with smooth tile. If this does not deal with the causative agent in some specific way, it at least minimizes the possibility of producing abrasions.

LUMBOSACRAL JUNCTION

ROENTGENOGRAPHIC COMPARISON OF PATIENTS WITH AND WITHOUT BACKACHES

Clarence A. Splithoff, M.D., Oakland, Calif.

Chronic lumbar backache continues to be a source of difficulty, both to the patient and to the physician called on for treatment. There is hardly a person who has not, at some time, experienced low backache. The vast majority of the backaches are transitory and will subside with little or no treatment. There are, however, many instances in which these bothersome backaches become chronic and tax the ingenuity and resourcefulness of the physician.

In order to determine the relationship between the roentgenographic findings and chronic lumbar backache, a study was made comparing 100 patients with backache and an equal number of persons not bothered by backache. The group of persons with chronic backache included the first hundred who applied for treatment at the New York Orthopedic Dispensary and Hospital in the year chosen for study. They were not screened except that those persons with obvious pathological changes, such as herniation of an intervertebral disk, tuberculosis, or other disease, were not included.

The 100 normal persons were unselected; they were at least 40 years of age; and they had never consulted a physician or been disabled by chronic backache. It became obvious very early in the study that it would be impossible to establish a group of so-called normal persons who could honestly state that they had never experienced an occasional backache; therefore, anyone who could say that he had never received medical attention for or been disabled by backache was accepted as normal for the study. This group included friends or relatives of patients or those who came for treatment of some condition entirely unrelated to the back.

The routine views used for the study were anterior-posterior and lateral roentgenograms of the lumbosacral spine, and a 45 degree cephalad-oblique view was utilized to visualize the fifth lumbar intervertebral disk and facets. The lateral view was taken with the legs extended in order to obtain a true measurement of the angle of the sacrum. The anomalies present, the position of the facets, the width of the fifth lumbar intervertebral disk, and the angle of the sacrum were recorded in each of the films.

RESULTS

The incidence of congenital anomalies and degenerative arthritis is summarized in table 1. Scoliosis or tilt and posterior displacement of the fifth lumbar vertebra are included here for completeness of detail. Except for scoliosis or tilt, it should be noted that congenital anomalies and degenerative arthritis were present in approximately the same percentage of patients with and without backache.

Transitional Vertebrae.—Transitional vertebrae were present equally in both groups. A vertebra was not considered transitional unless the enlargement of the transverse process was quite distinctive.[1] Simple butterfly enlargement of the presacral transverse process was not considered transitional. No attempt was made to determine whether the transition represented sacralization or lumbarization because our films did not always include the upper lumbar vertebrae. The transition could include enlargement of either one or both lateral masses of the sacral type progressing to pseudoarthrosis or in some cases to actual fusion to the sacral wing.

TABLE 1.—*Incidence of Changes Observed at Lumbosacral Junction as Shown by Roentgenograms of 100 Persons With and 100 Persons Without Backache*

Type of Change	Normal	Backache
Transitional vertebra	10	10
Spondylolisthesis	3	2
Spina bifida occulta	6	4
Posterior displacement of fifth lumbar vertebra	14	16
Scoliosis or tilt, lumbar spine	9	16
Osteoarthritis	22	26

Spondylolisthesis.—Spondylolisthesis has always presented considerable question regarding its origin and its relation to lumbar backache. That this condition can be present without backache is demonstrated in this series; 3% of normal persons presented this condition and 2% of these with backache had it. Breck, Hillsman, and Basom [2] have reported spondylolisthesis in 3% of 450

Dr. Allen DeF. Smith aided in the preparation of the manuscript.

The research data for this paper were obtained while the author was a fellow at the New York Orthopedic Dispensary and Hospital.

[1] Ferguson, A. B.: Roentgen Diagnosis of the Extremities and Spine, Annals of Roentgenology, ed. 2, edited by J. T. Case, New York, Paul B. Hoeber, Inc., 1949, vol. 17, p. 426.

[2] Breck, L. W.; Hillsman, J. W., and Basom, W. C.: Lumbosacral Roentgenograms of 450 Consecutive Applicants for Heavy Work, Ann. Surg. 120: 88, 1944.

men applying for heavy work in a mine. Allen and Lindem[3] report 2.96% in 3,000 normal preemployment examinations.

Such a condition can be of utmost importance in industrial liability in instances in which an injured worker may claim aggravation of a preexisting condition or in medicolegal action in which traumatic origin may be claimed. Ferguson[4] states that overdevelopment of the first sacral vertebra may take place in the presence of spondylolisthesis and may broaden the anterior-posterior diameter of the first sacral vertebra. The degree of overdevelopment indicates the duration of forward slipping.

Posterior Displacement.—Posterior displacement of the fifth lumbar vertebra on the first sacral was recorded in 16 patients with and 14 patients without backache. There is some disagreement as to the relationship that this bears to backache. Smith[5] considers it important roentgenographically in the presence of backache and feels that its occurrence depends on the structure of the facets of the lateral articulations. Willis[6] has cited reasons for which this posterior displacement cannot occur. It was seen in normal persons in this study as well as in those with backache; hence, the presence of so-called posterior displacement in itself is not necessarily associated with backache. Willis has further stated that, in some roentgenograms, the inferior surface of the fifth lumbar vertebra is wider than the superior surface of the first sacral vertebra and produces, thereby, an apparent posterior displacement. I found by actual measurement that this does occur. It is conceivable that a combination of anterior-posterior facets and thinning of the lumbosacral intervertebral disk does result in displacement of the fifth vertebra posteriorly.

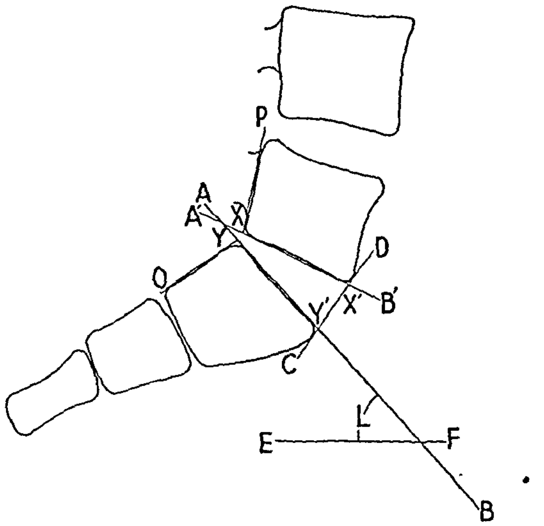

Fig. 1.—Method of measuring the angle L of sacrum. Line E-F represents lower horizontal edge of film, and A-B represents a line parallel to the superior surface of the sacrum. The width of fifth lumbar intervertebral disk is measured anteriorly from X' to Y' and posteriorly from X to Y.

Spina Bifida.—Spina bifida occulta was found in 6% of normal subjects and 4% of the patients with backache. No attempt was made to designate the defect level. Breck, Hillsman, and Basom[2] report 6% in 931 examinations of normal applicants for railroad work. Badgley[8] reported the condition in 9.5% or 43 out of 447 cases of low back pain seen at the University of Michigan clinic in 1934. It is apparent that the condition exists rather frequently in both normal persons and those with back symptoms.

Scoliosis.—Scoliosis or tilt, which are two entirely different and unrelated conditions, were recorded together because of the difficulty of differentiating each without films of the entire spine. It is obvious that a distinct structural scoliosis would have been easy to discern and listed as such. For the purpose of this paper, however, any deviation of the spine from the midline was recorded under this heading.

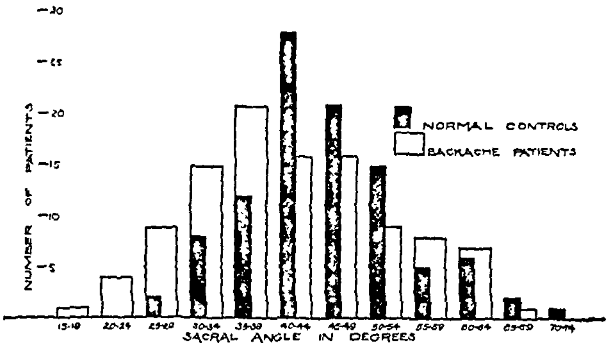

Fig. 2.—Comparison of angle of sacrum in patients with and without backache. The slight decrease of the angle in those with backache is demonstrated.

Osteoarthritis.—Osteoarthritis took the form of moderate lipping in its mildest form, but in some cases it was so extensive that the bodies of some vertebrae were bridged by bone. The condition was present in 22% of the normal and 26% of patients with backache. No attempt was made to differentiate between the mild and severe cases. The minimum age of 40 was required in the normal group so that we could be fairly certain that changes would be present, at least in mild form. The group with backache included all ages. It was anticipated that the contribution of degenerative changes to backache might be determined.

Badgley[8] reports degenerative changes in 20.1% of 447 patients with low backache. Breck, Hillsman, and Basom[2] report changes in 21% of their 450 normal applicants for work (8% severe and 13% mild). The ages in their group were not given. Barton and Biram[9] report 17.3% in 1,000 preemployment examinations for a subsidiary of the General Motors Company. It is, therefore, quite apparent that degenerative changes are present in a large number of persons and in close ratio in

backache and 35 normal controls. They reported 5 mm. as normal in both men and women for the posterior disk and 13 mm. for women and 18 mm. for men as normal anterior disk measurements. Under these conditions, 5.3% of the control patients and 20.6% of those with backache showed a normal posterior disk, and 17.1% of the controls and 19.1% of those with backache showed a narrow anterior disk.

Lumbosacral Facets.—Position of lumbosacral intervertebral facets was also considered. A great deal has been published concerning the position of the lumbosacral facets with relation to the stability of this joint. It has been stated that the stablest joint contains facets in the sagittal plane, the so-called internal-external type, and that the least stable is a combination of one anterior-posterior and one oblique or internal-external.

The position of facets at the lumbosacral junction was recorded in both groups according to Ferguson's[12] description, and the various combinations were recorded (table 2). The most frequent position in both groups was in the coronal or anterior-posterior plane and was present in about equal percentages. The anterior-posterior facets would seem to be most representative of the average because they appeared in 59%. This type of facet is not necessarily the stablest. It may be further stated that no facet position can be stable in all directions and under all contingencies.

Age and Sex.—Although backache may occur at any age, it is commonest in both men and women between 40 and 49 years (fig. 4). There are probably a number of reasons for this, the most outstanding being physical decline, obesity, sedentary existence, and occupational factors. It appears that women are more susceptible to backache in the proportion of 60 to 40 and that they are susceptible at an earlier age than men. The figures given here are those obtained at a private clinic and, therefore, do not take into account the large number of industrial injuries occurring in laborers cared for under compensation insurance.

SUMMARY AND CONCLUSIONS

This study has demonstrated fairly conclusively that the findings on roentgenograms of the lumbosacral region of normal persons and of those with backache are quite similar. Congenital anomalies and other anatomic details appear in close numerical sequence. Degenerative changes are somewhat frequenter in patients with backache, and the sacral angle is slightly less in this group. There is no significant difference in the width of either the anterior or posterior disk measurement in either group.

* Cushway, B. C., and Maier, R. J.: Routine Examination of the Spine for Industrial Employees, J. A. M. A. 92: 701 (March 2) 1929.

It is recognized that the groups reported here are not large; however, this is the largest study reported in which patients both with and without backache were studied in the same institution and in which significant trends are indicated. Compared with reports by other authors (table 3) on normal persons or on a large group of persons with backache, the collective results presented here agree very closely.

The fact that the findings in both groups so closely parallel each other does not discount the importance of routine roentgenographic study in all cases of chronic backache. It is obvious that many factors other than bone structure play a part. The structure of the back as visualized in the film is, however, of great importance not only in diagnosis but also in planning treatment.

The findings from roentgenograms of the vertebral columns of 100 persons without backache are compared with those of the same number of persons with backache. In both groups, there is no significant numerical difference in the incidence of structural variation. The most frequent facet position at the lumbosacral junction is oblique or anterior-posterior in both series. Osteoarthritis is present to a slightly greater extent in patients with backache. The group having backache included persons of all ages, whereas the normal group included only persons who were 40 or over. The width of the fifth lumbar intervertebral disk is approximately equal in both types of persons. The measurements that were found most frequently were 15 mm. anteriorly and from 3 to 5 mm. posteriorly.

---

[12] Ferguson,[1] p. 421.

Relationship of Physician and Patient.—Medical students in their search for psychological truth about themselves and their fellows might utilize Harry Stack Sullivan's concept of "participant observation." . . . The future physician should be instructed that his relationship with the patient, any patient, is always what Sullivan would call an inter-personal process, in which the doctor is involved as much as the patient—involved first as an observer, and second as a therapist. In both capacities the physician will require a certain amount of awareness of his own emotional problems and needs as well as his physical adaptation patterns to enable him to achieve a relative degree of objectivity in observing and dealing with his patient's problem of living.—D. R. MacCalman, M.D., Observations on the Teaching of the Principles of Mental Health to Medical Students, *British Journal of Medical Psychology*, Part 2, 1953.

unselected, normal persons over the age of 40 and in those with backache.

Angle of Sacrum.—Angle of sacrum was measured to determine its relationship to the presence or absence of backache. The angle was measured in the lateral film in both groups. In order to assure that the angle on the film would be accurate as measured, the lateral film was taken with femurs extended so that the longitudinal axis of the patient would form a right angle with the bottom margin of the film. This position permitted the use of the lower edge of the film as the base line. Angles could be erected as shown in figure 1 with E-F as base line and line A-B parallel to the superior surface of the first sacral vertebra. This formed angle L as the angle of the sacrum.

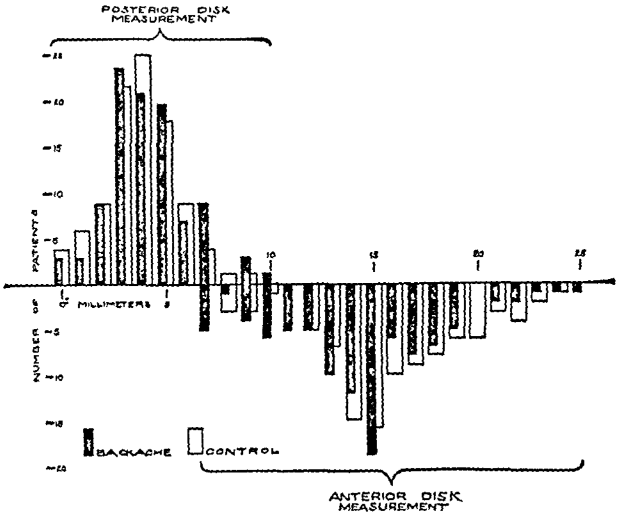

Fig. 3.—The width of the fifth lumbar intervertebral disk in 100 normal persons and 100 persons with backache.

The measurements thus obtained were plotted graphically (fig. 2); the angle in the largest number of normal persons fell between 40 and 44 degrees, whereas in the greatest number of patients with backache it fell between 35 and 39 degrees. There seemed to be a shift throughout the group with backache to a lesser sacral angle. This indicated either that muscle spasm was present and, thus, flattening of the lumbar spine occurred or that patients with backache learn that they are more comfortable if the back is flattened and thus automatically assume this position.

Von Lackum,[10] in 1924, showed the importance of this sacral angle. In a study of cadavers and roentgenograms, he determined the average angle to be 42.5 degrees. If the angle is increased, the shearing strain or stress in an anterior direction is proportionately increased. If the sacral angle measures 35 degrees, the pressure tending to slide forward is 0.57% of the superimposed weight, whereas, if the angle increases to 45 degrees, the strain increases to 0.71%, and at 75 degrees the strain is 0.97%.

The relation of the center of gravity to the sacral angle and lumbosacral joint is also important. This relationship can be represented by passing a vertical line through the center of the body of the third lumbar vertebra in the erect position. If the angle of the sacrum is increased, this line may lie anterior to the first sacral vertebra, indicating an increase in the shearing strain at the lumbosacral junction. Normally the line should lie in the first sacral vertebra. It is obvious that the relationship of the sacrum to the pelvis cannot be changed, because these structures comprise a fixed unit; however, it should be equally obvious that the relationship of the sacrum to the vertical axis can be changed by appropriate orthopedic measures and correction of improper posture.

TABLE 2.—*Position of Facets at the Lumbosacral Junction as Shown by Roentgenograms of 100 Persons With and 100 Persons Without Backache*

Type of Facet	Normal	Backache
Anterior-posterior, bilateral	59	55
Internal-external, bilateral	4	1
Asymmetric		
Left internal-external Right anterior-posterior	9	7
Left anterior-posterior Right internal-external	15	19
Oblique, bilateral, or one internal-external	13	18
Rudimentary	4	0
Indeterminate facets	0	0

Fifth Lumbar Disk.—Width of fifth lumbar intervertebral disk was measured and is presented graphically in figure 3. The question of the normal size of the fifth lumbar intervertebral disk constantly arises in interpretation of roentgenograms of the lumbosacral spine. This in turn raises the question of the significance of a narrow disk in the presence of lumbar backache.

The width of the disk was measured in each of the 200 lateral films (fig. 1). Lines A-B and A′-B′ were established parallel to the superior and inferior surfaces respectively. Line C-D and lines X-Y and X′-Y′ were determined by divider and ruler. It can be seen, by studying this graph as a whole, that the width of the disks in both groups closely approximate each other, although there was tendency to narrowing of the posterior measurement in the group with backache. This difference is, however, very slight. It will be noted further that in four patients without and in three with backache the posterior disks were so narrow that they were recorded as zero. The greatest posterior width was 10 mm.

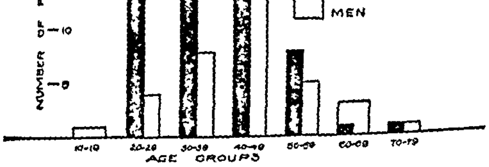

Fig. 4.—Comparison of men (40) and women (60) indicates that incidence of backache increases up to the fourth decade.

The anterior disk measurement showed greater variation; the smallest measurement was 7 mm., and the greatest measurement was 25 mm. Both extremes were found in patients with backache. The largest number of anterior disk measurements in both groups were 15 mm.

A comparable study has been recorded by Brav, Bruck, and Fruchter[11] reporting on 70 patients with backache and 35 normal controls. They reported 5 mm. as normal in both men and women for the posterior disk and 13 mm. for women and 18 mm. for men as normal anterior disk measurements. Under these conditions, 5.3% of the control patients and 20.6% of those with backache showed a normal posterior disk, and 17.1% of the controls and 19.1% of those with backache showed a narrow anterior disk.

Age and Sex.—Although backache may occur at any age, it is commonest in both men and women between 40 and 49 years (fig. 4). There are probably a number of reasons for this, the most outstanding being physical decline, obesity, sedentary existence, and occupational factors. It appears that women are more susceptible to backache in the proportion of 60 to 40 and that they are susceptible at an earlier age than men. The figures given here are those obtained at a private clinic and, therefore, do not take into account the large number of industrial injuries occurring in laborers cared for under compensation insurance.

SUMMARY AND CONCLUSIONS

This study has demonstrated fairly conclusively that the findings on roentgenograms of the lumbosacral region of normal persons and of those with backache are quite similar. Congenital anomalies and other anatomic details appear in close numerical sequence. Degenerative changes are somewhat frequenter in patients with backache, and the sacral angle is slightly less in this group. There is no significant difference in the width of either the anterior or posterior disk measurement in either group.

It is recognized that the groups reported here are not large; however, this is the largest study reported in which patients both with and without backache were studied in the same institution and in which significant trends are indicated. Compared with reports by other authors (table 3) on normal persons or on a large group of persons with backache, the collective results presented here agree very closely.

The fact that the findings in both groups so closely parallel each other does not discount the importance of routine roentgenographic study in all cases of chronic backache. It is obvious that many factors other than bone structure play a part. The structure of the back as visualized in the film is, however, of great importance not only in diagnosis but also in planning treatment.

The findings from roentgenograms of the vertebral columns of 100 persons without backache are compared with those of the same number of persons with backache. In both groups, there is no significant numerical difference in the incidence of structural variation. The most frequent facet position at the lumbosacral junction is oblique or anterior-posterior in both series. Osteoarthritis is present to a slightly greater extent in patients with backache. The group having backache included persons of all ages, whereas the normal group included only persons who were 40 or over. The width of the fifth lumbar intervertebral disk is approximately equal in both types of persons. The measurements that were found most frequently were 15 mm. anteriorly and from 3 to 5 mm. posteriorly.

Relationship of Physician and Patient.—Medical students in their search for psychological truth about themselves and their fellows might utilize Harry Stack Sullivan's concept of "participant observation." . . . The future physician should be instructed that his relationship with the patient, any patient, is always what Sullivan would call an inter-personal process, in which the doctor is involved as much as the patient—involved first as an observer, and second as a therapist. In both capacities the physician will require a certain amount of awareness of his own emotional problems and needs as well as his physical adaptation patterns to enable him to achieve a relative degree of objectivity in observing and dealing with his patient's problem of living.—D. R. MacCalman, M.D., Observations on the Teaching of the Principles of Mental Health to Medical Students, *British Journal of Medical Psychology,* Part 2, 1953.

ESOPHAGEAL ATRESIA AND TRACHEOESOPHAGEAL FISTULA

John B. Grow, M.D.
and
A. J. Neerken, M.D., Denver

Formerly considered a mere curiosity in pathological annals, esophageal atresia and tracheoesophageal fistula have recently assumed a new importance to all physicians who deal with the care of the newborn infant. The disease itself has been known for many years, and Durston described the condition accurately in 1670.[1] The first attempt at surgical treatment, a gastrostomy, was made in 1888; however, it was in 1913 that Richter suggested the operation that is followed today, i. e., closure of the fistula and reestablishment of the continuity of the esophagus.[2] To Haight (1941) goes the credit for the first successful one stage operative repair.[3]

A consideration of the normal embryologic development of the trachea and esophagus is of interest, since it will explain the occurrence of the anomaly. The trachea and esophagus originate as a common portion of the foregut. Early in the second month of intrauterine life two lateral ridges of mesoderm develop, which push the endoderm in to fuse in the midline, forming a complete septum. It is apparent that failure of development of a portion of this septum would result in a fistula between the esophagus and trachea. After delineation of these two structures has occurred, the epithelial lining of the esophagus proliferates rapidly, so that the lumen disappears, leaving a solid cord of cells. Embryologists differ in opinion as to whether this solid cord extends for the entire length of the esophagus or occurs only in localized areas. Most agree that some degree of transient obliteration of the esophageal lumen takes place. Recanalization then follows as the esophagus assumes its definitive state. Should the recanalization be incomplete, an area of atresia results (fig. 1).

There are other theories of the development of this anomaly. Fluss and Poppen believe pressure from anomalous vessels to be responsible and cite three cases in which aberrant vessels passed behind the esophagus at the level of the defect.[4] Ingalls and Prindle, in a study of 107 cases in the Boston area, found maternal hydramnios to have been present in 25%. They believe increased pressure in the pneumoenteric recesses, two laterally placed prolongations of the peritoneal cavity that extend along the developing foregut, to be an important etiological factor.[5] The anomaly may take any form, from atresia of the lower two-thirds of the esophagus with no connection to the trachea to a completely patent esophagus with a tracheoesophageal fistula. By far the commonest defect is a blind upper esophageal pouch with the distal esophageal segment communicating with the trachea near its bifurcation.

DIAGNOSIS

The diagnosis of this disease is not difficult if its possibility is kept in mind. Any newborn infant who exhibits the triad of excessive salivation, choking and cyanosis, and vomiting and aspiration of oral feeding must be considered suspect. The obstruction to passage of a soft 8-F or 10-F urethral catheter into the stomach is almost certain evidence of esophageal atresia. X-ray examination will give further information. After a catheter has been passed into the esophagus until it meets obstruction, 1 to 2 cc. of iodized poppy seed oil (40%) is instilled. Usually a blind upper pouch will be seen. Its level should be noted, since this offers some idea of the length of the atretic esophagus. It is also important to examine the lung fields carefully for the presence of atelectasis or pneumonia. Absence of air in the stomach indicates a type 1 defect (esophageal atresia without tracheoesophageal fistula) or occasionally a tracheoesophageal fistula so small that air has not passed through the fistula into the stomach. The characteristic findings in the type 3 anomaly (blind upper pouch with lower esophageal segment connecting with trachea) can be seen in figure 2.

PROCEDURE

Preoperative Preparation.—Most infants are several days old before they undergo surgical treatment and are often dehydrated. Accordingly, parenterally administered fluids are necessary. Incision and cannulation are made into an ankle vein. We agree with Potts that these infants may be easily overhydrated and that conservatism in the administration of fluids is in order.[6] Forty to fifty cubic centimeters of fluid per pound of body weight should be given. Not more than 20 cc. per pound should be given in the form of a 0.45% saline solution. To give more salt invites pulmonary edema. A blood cell count is taken when the patient is hydrated and whole blood given if indicated.

The most frequent preoperative complications in these infants are pulmonary. Atelectasis and pneumonitis result from the aspiration of saliva that cannot be swallowed and gastric secretions that pour from the stomach into the trachea through the fistula. It is important that aspiration of oral secretions be minimized by frequent cleansing of the mouth and pharynx with a soft rubber catheter attached to the mechanical suction apparatus. We feel that ordinarily bronchoscopy and laryngoscopy are to be avoided, since even minimal trauma to the glottis is undesirable. The patient is placed in an incubator on admission to the surgical service, and oxygen is ad-

ministered. Antibiotics in the form of procaine penicillin and dihydrostreptomycin are given in a further attempt to combat pneumonitis.

Operation.—Surgical correction of the anomaly should be undertaken as soon as the infant reaches a reasonably satisfactory condition. This can ordinarily be done in 6 to 12 hours. If pneumonia is extensive it may be wise to delay surgery for 24 hours. Seldom should operation be postponed longer than this.

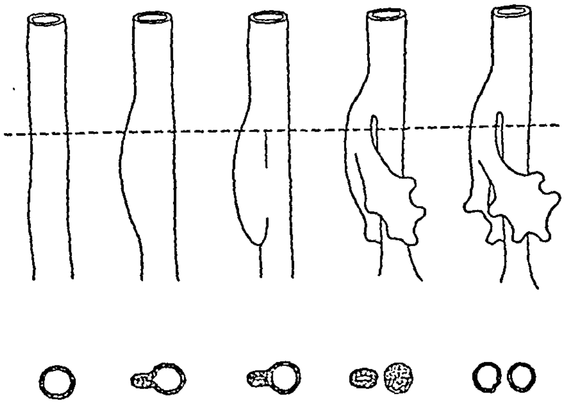

Fig. 1.—Embryologic development of the trachea and esophagus.

A right-sided approach is desirable, since this keeps the aortic arch out of the operative field; however, if pulmonary complications are marked on the left and the right lung is relatively clear, it is prudent to operate from the left. In the type 1 anomaly (esophageal atresia without tracheal fistula) the distal segment of esophagus is apt to be very small and may be only a fibrous cord. Thus, preoperative diagnosis of a type 1 defect also calls for a left-sided operation so that a portion of stomach may be brought up into the chest if necessary. Anesthesia may be given by intratracheal tube or face mask. If difficulty is encountered in the introduction of the intratracheal tube, it is wise to abandon it and resort to the face mask. Every precaution must be taken to avoid glottic edema.

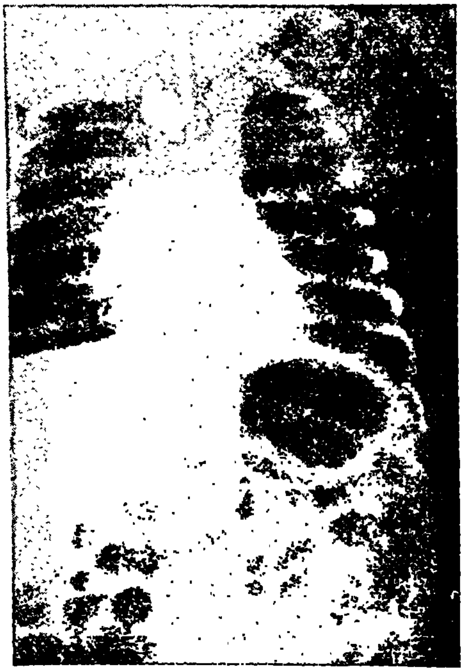

Fig. 2.—Type 3 anomaly. Note the blind upper pouch containing iodized poppy seed oil (40%) and the presence of gas in the gastrointestinal tract. Eighteen of the 20 cases reported herein are of this type.

The patient is placed on the operating table in the lateral decubitus position with the right side up. Incision is made along the course of the fourth rib from 2 cm. lateral to the spine to the anterior axillary line. The pleural cavity is then entered through the fourth interspace and the lung retracted anteriorly with sponge sticks. The mediastinal pleura is opened and the azygos vein identified and divided between ligatures. The distal segment of the esophagus is then located and followed to its communication with the trachea. The fistula is divided and the tracheal side closed with one or two mattress sutures of nonabsorbable surgical strands.

The proximal pouch of esophagus is then identified. This may be facilitated by having the anesthetist pass a catheter into it. The proximal segment is usually well developed and has an excellent blood supply. This is not true of the distal segment. Therefore, the defect should be bridged by bringing the proximal segment down to the distal, leaving the latter as undisturbed as is reasonable. Stay sutures are placed in the proximal segment to control it while the anastomosis is being made. It is important to handle the esophagus with forceps as little as possible. An opening the size of the distal segment is then made in the lowermost portion of the upper segment. An anastomosis is made using interrupted sutures of 5-0 silk. A two layer anastomosis is desirable, but often only one layer of sutures can be placed without putting undue tension on the segment. After the posterior sutures have been placed, the catheter in the proximal esophagus is advanced into the stomach and the anastomosis completed (fig. 3 and 4).

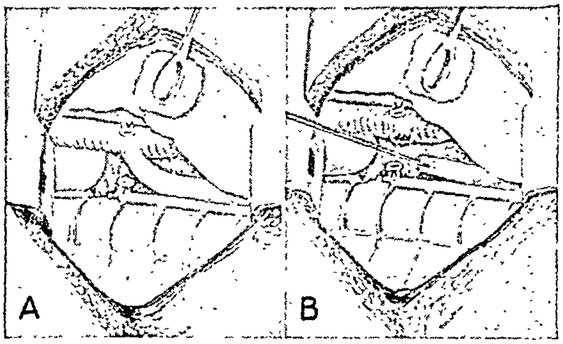

Fig. 3.—Procedure in surgical closure of the tracheoesophageal fistula and anastomosis of the esophageal segments. *A*, the azygos vein has been divided. The blind upper pouch can be seen on the left. The lower esophageal segment connects with the trachea. *B*, the fistula has been divided and the defect in the trachea closed with mattress sutures.

The mediastinal pleura in these babies is so thin that it is usually impossible to reapproximate it over the anastomosis. Two 16-F catheters are used to drain the pleural space. They are brought out through stab wounds located anteriorly in the third interspace and posterolaterally in the eighth, and are connected to water-sealed bottles. The chest is closed in layers with interrupted nonabsorbable surgical sutures.

The patient is then turned on his back and a Stamm gastrostomy made. The catheter is fished out of the stomach, a heavy nonabsorbable surgical suture tied to it, and the catheter withdrawn through the mouth. The two ends of the suture are tied together, and it is left as a guide in the event that postoperative dilations should be necessary. During the operation the estimated blood loss is made up by transfusions. The baby is returned to the postoperative ward in his incubator.

Postoperative Care.—The gastrostomy tube is connected to Wangensteen suction. The stomach is kept decompressed by this method for 48 hours. During this time fluid balance is maintained parenterally. If the infant's condition is satisfactory, water and formula are then started by slow drip through the gastrostomy tube. The stomach should not be permitted to become distended, allowing regurgitation to take place.

On the third postoperative day glucose solution is offered by mouth. If this is taken without difficulty, formula is given. A leak in the anastomosis, if present, will be manifested by the presence of milk curds in the chest drainage. In the event that this occurs, continuous suction of 10 to 15 cm. of water is applied to the chest bottles. If the anastomosis is watertight, a portable chest film is obtained to prove the complete reexpansion of the lung and the tubes removed from the chest.

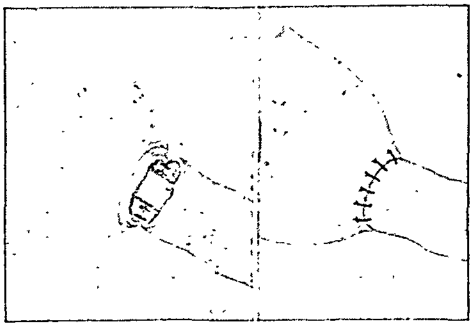

Fig. 4.—After the posterior sutures have been placed, a catheter is passed into the stomach and the anastomosis completed.

Throughout the early postoperative period the patient is given antibiotics. Before discharge from the hospital a barium esophagram is obtained. If there is evidence of stricture, the string through the esophagus and the gastrostomy is left in place. Leakage through the gastrostomy is minimized by use of a plastic button placed in the stoma. If dilations are necessary, they are done in the retrograde manner. The gastrostomy should not be allowed to close until the child has proved the adequacy of his esophageal lumen by several months without dilations.

ANALYSIS OF CASES

During the three year period from April, 1948, to April, 1951, 20 patients with esophageal atresia were managed with this program. The type 3 anomaly occurred 18 times, and types 1 and 5 once each. The average age at which these infants reached the operating table was 2.4 days—somewhat earlier than the average reported in many series. We feel this reflects considerable credit on the diagnostic acuity of the pediatricians and obstetricians practicing in our area. Seven of the 20 patients had atelectasis and pneumonitis preoperatively. It is interesting to note that this group with pulmonary complications shows an average age no different from the series as a whole, suggesting that age alone is not the important factor in preoperative pneumonia. Of these seven patients, five recovered (71.4%), a survival rate better than that for the entire series. We have found the size of the infant of greater prognostic significance. Thus, of our 20 patients four weighed less than 5 lb. (2.3 kg.). None of these is alive.

Five patients in this series had other congenital anomalies; they included (1) incomplete rotation of gastrointestinal tract and patent foramen ovale (only partially covered by septum primum), (2) double aortic arch, (3) club feet, vertebral anomalies, and deformities of joints, (4) hypospadias and cleft soft palate, and (5) a supernumerary thumb. None of these anomalies was incompatible with life.

Of the 20 patients, 11 survived. One death occurred on the operating table. The other eight occurred during the early postoperative period. Autopsy was conducted at all deaths. The findings were (1) a leak in anastomosis in six (67% of deaths), (2) pulmonary complications (hyaline membranes in three [33%] and patchy atelectasis and bronchopneumonia in nine [100%]), (3) kernicterus in two, and (4) central nervous system birth trauma in one.

Several of these findings are worthy of comment. The most prominent cause of death is failure of the anastomosis. This accounted for two-thirds of the deaths. The importance of an anastomotic leak is further emphasized by the fact that, of the seven patients in whom a leak developed, only one survived. This is in marked contrast to the many reports in the literature of patients surviving esophageal-cutaneous fistulas when the extrapleural operation was used. There can be no question but that this is a serious drawback to the transpleural approach.

Pulmonary hyaline membranes were found in three patients. In two of these this must be considered the primary cause of death. The third patient also had an esophagopleural fistula. Pulmonary hyaline membranes are now recognized as a leading cause of neonatal death, probably accounting for from 25 to 50% of deaths in this age group.[7] It is interesting to note that at thoracotomy in the three patients with this finding no gross abnormality was noted in the lungs.

Four patients required esophageal dilation postoperatively. This was done by the retrograde route. In one of these infants nearly complete obstruction developed three months after the child left the hospital. Esophagoscopy was performed and was followed by mediastinitis. Emergency thoracotomy was carried out; the area of perforation, which was found to be at the site of an old, apparently sterile mediastinal abscess, resected; and end-to-end anastomosis done. The patient has since done well.

SUMMARY

The diagnosis of esophageal atresia is based on the finding of excessive salivation, choking and cyanosis, and vomiting and aspiration of oral feedings. The treatment of choice is surgical closure of the tracheoesophageal fistula and anastomosis of the esophageal segments as a one stage procedure. Of 20 patients operated on between 1948 and 1951 by the transpleural route, 11 survive.

PERITONEOSCOPY IN MALIGNANT LESIONS OF THE ABDOMEN

Samuel J. Zoeckler, M.D., Philip G. Keil, M.D.
and
George J. Hegstrom, M.D., Des Moines, Iowa

The value of peritoneoscopy, direct cholangiography, and liver biopsy in the diagnosis and treatment of hepatic and biliary tract disease has been established.[1] Use of the peritoneoscope in evaluation of the patient with carcinoma has not been sufficiently stressed. The diagnosis of intra-abdominal malignant lesions can frequently be established by this procedure. During the period November, 1949, to December, 1952, we performed 660 peritoneoscopic examinations. Of these, 84 were on patients with known or suspected carcinoma. A review of these cases forms the basis for this report.

METHOD

The records of 84 patients examined peritoneoscopically for possible malignant lesions were reviewed. The patients were placed in one of three groups: (1) group A, patients with a clinical diagnosis of carcinoma, in whom it was desired to establish operability; (2) group B, patients with previously resected carcinoma, in whom the presence of recurrence or metastases was suspected, and (3) group C, patients with a clinical diagnosis of carcinoma, in whom the diagnosis was proved incorrect at the time of peritoneoscopy. Each group was then reviewed from the standpoint of accuracy of diagnosis and evaluation of the procedure.

RESULTS

Groups A and B comprise all patients with a proved diagnosis of carcinoma. The average age of the combined group was 57.8 years. The youngest was 25, and the eldest 75 years. All but four patients were men, a factor controlled by the nature of our hospital.

Group A (table 1).—This group comprised 39 patients, each with a clinical diagnosis of carcinoma. Radiological and laboratory studies had ruled out obvious metastatic lesions. Peritoneoscopic examination was performed to rule out intra-abdominal metastases. Of the 39 patients, 20 (51.3%) had metastatic carcinoma in the liver, omentum, peritoneum, or a combination of these locations. In 13 of these 20 cases biopsy of a tumor nodule was obtained by the forceps technique. Twelve (30.8%) had no visible metastases. In five patients (15.4%) peritoneoscopy was unsatisfactory and laparotomy advised. Failure was due in two instances to the production of pneumo-omentum and in one each to marked small bowel distention, dense adhesions from previous operation, and to peritonitis. Of the 12 patients with no visualized metastases, 7 had resectable lesions at surgery. The remainder had local extension or vascular invasion, which precluded resection of the primary lesion.

Group B (table 2).—Eighteen patients comprised this group. In each instance a resection had been done previously for carcinoma. In no instance had metastases been found beyond the regional nodes. All were admitted because of recurrence of symptoms or routine recall by the tumor registry. Peritoneoscopy was then performed. Nine (50%) were found to have intra-abdominal metastases. Five (27.8%) had no evidence of recurrence or metastases. The procedure was unsatisfactory in four patients (22.2%). The limiting factor in these four was the presence of massive postoperative intra-abdominal adhesions. Two of these were later explored and metastases demonstrated. One refused exploration, and roentgen evidence of pulmonary metastases developed. The fourth patient had previously been found to have transitional cell carcinoma metastatic to the inguinal nodes. Exhaustive study of the genitourinary and other organ systems has failed to reveal a primary growth.

Group C (table 3).—There were 27 patients in this group; 25 were men. The average age was 60.2 years, the youngest was 25, and the eldest 84 years. Twenty-five patients (93%) had a clinical diagnosis of intra-abdominal carcinoma that could not be refuted by physical examination or roentgen and laboratory studies. Of these, 13 (52%) had advanced portal cirrhosis peritoneoscopically and histologically. In five (20%) the liver and abdominal contents appeared normal and liver structure was normal. These five patients had inanition on the basis of gastritis, chronic glomerulonephritis, hypertensive cardiovascular disease, chronic duodenal ulcer, and severe dental sepsis. Five patients had chronic hepatitis, one in association with subacute bacterial endocarditis, one with chronic duodenal ulcer, and another with tuberculous peritonitis; the remaining two patients had no concomitant disease. There were two instances in which carcinoma of the uterus was diagnosed clinically. In both cases peritoneoscopy revealed myomas of the uterus. One was proved at operation; the other patient has postponed surgery.

COMMENT

Diagnostic laparotomy has been commonly employed in the elucidation of unexplained ascites and abdominal masses. It is performed on patients in whom metastases are suspected in order to establish a diagnosis. It is generally agreed that only a palliative surgical procedure is indicated in the presence of multiple hepatic, omental, or peritoneal metastases. In such instances, laparotomy

becomes a useless procedure and would not usually be advised if the true nature of the disease were known.

Peritoneoscopic examination affords excellent visualization of the organs within the peritoneal cavity. Biopsy by forceps can be obtained under direct vision from liver or metastatic implants in omentum and peritoneum. The biliary tree may be outlined by injection of radio-opaque material into the gallbladder under visual control. The mortality is less than 0.1%, and the procedure causes little discomfort. The patient may be hospitalized for one day or less.

In the evaluation of intra-abdominal malignant lesions, the determination of operability is often difficult. A survey for metastatic lesions is readily accomplished by physical examination and roentgenographic studies. Since we began using peritoneoscopy as a part of our routine study of patients with suspected malignant lesions, 51.3% have been spared laparotomy. In these cases a clinical diagnosis of carcinoma without evidence of metastases had been established. Peritoneoscopy revealed metastatic lesions. In addition, over half of the 30.8% in whom no metastases were found at peritoneoscopy had operable lesions. The remainder were inoperable because of involvement of vital structures.

An equally important group of patients is comprised of those who return with various symptoms after resection of a malignancy. We have found recurrence or metastases in 50% of such patients and no recurrence in 27.8%. It is probable that most of these patients would have been advised to undergo further operative procedures.

Those patients in whom we have been able to refute the diagnosis of intra-abdominal malignant lesions constitute an important group. Clinically they showed marked emaciation, ascites, jaundice, and a history of dyspepsia. Clinical evaluation in each was suggestive of malignancy. Peritoneoscopy in these patients revealed such diverse conditions as portal cirrhosis, tuberculous peritonitis, cholelithiasis, subacute bacterial endocarditis, and uterine myoma. In some no evidence of intra-abdominal disease was found and the patient was suffering from severe malnutrition secondary to nonmalignant disease. In the entire group there were no complications and no deaths as a result of the procedure. Peritoneoscopic examination was unsuccessful in 10.7% (9 cases). The usual cause for failure to adequately visualize structures within the peritoneal cavity was the presence of massive adhesions from previous operative procedures (five patients). In two instances the procedure proved unsatisfactory because of pneumo-omentum.

A markedly distended bowel will produce a similar effect and was encountered in one case. Peritoneoscopy failed in one instance because of peritonitis, with adhesions of bowel to abdominal wall.

Peritoneoscopy is not intended to replace exploratory laparotomy. Like the roentgenologic and laboratory study it is an aid in the complete evaluation of gastrointestinal problems. It is a valuable procedure in the diagnosis and management of the patient with carcinoma.

SUMMARY

Metastatic lesions were demonstrated in 51.3% of patients who appeared to have localized carcinoma by conventional roentgenologic and laboratory studies. Recurrent or metastatic carcinoma was demonstrated in 50% of patients who had undergone previous resections for operable carcinoma. Ninety-three per cent of patients with a diagnosis of malignant lesions, based on clinical findings that could not be refuted by appropriate laboratory and roentgenologic studies, were shown peritoneoscopically to have diseases other than carcinoma. Peritoneoscopy is a valuable procedure in the diagnosis and prognosis of carcinoma involving intraperitoneal structures.

Education for Professional Services.—The professional man must act in a three fold capacity. He must appear simultaneously as skilled servant, as sage and as priest. In no professional role is this trinity more fully illustrated than in that of the physician. Knowledge is needed and often most detailed knowledge sharpened into tempered skill; but that is not enough. Wisdom must be there to condition knowledge; *but that is not enough.* Understanding must guide skill and humanize wisdom and then only do we see the great physician. Surely it will be conceded that quite apart from technical competence and medical knowledge the physician must be wise in his understanding of human beings; therefore it follows that his education must be sufficiently broad, sufficiently humane that it will discover and develop those qualities of mind which later will be required to direct technical skill. The basis on which such an education can best be built is afforded by the traditional liberal curriculum which sprang from the humanities.—S. Dorst, M.D., Education for Professional Services, *The Pharos of Alpha Omega Alpha Honor Medical Society,* May, 1953.

CLINICAL NOTES

MYELOID METAPLASIA WITH TERMINAL LEUKEMIA

REPORT OF A CASE

Robert S. Long, M.D.
Eugene E. Simmons, M.D.
and
John R. Schenken, M.D., Omaha

The patient in this case presented a difficult diagnostic hematological problem, with clinical and laboratory variations suggesting different disease processes existing at various times during the course of her illness. A single positive diagnosis could not be established until rather late in her course. The reason for reporting this case is to suggest that many reports in the literature of seemingly different disease processes may be in reality only observations of varying stages of the same basic disease.

REPORT OF A CASE

A 60-year-old white widow was referred for examination on Sept. 20, 1948, because of a tumor mass in the left upper portion of the abdomen. Her chief complaint was a feeling of fatigue, which had been present for several months but was not increasing appreciably. She had also noted a feeling of pressure or weight in the left side of the abdomen and left flank, and she was not completely comfortable while sitting or while lying on the left side. She stated that her appetite was fairly good and that she had not lost any weight. There were no definite symptoms referable to any body system other than nervous indigestion consisting of mild upper abdominal distress and gaseous eructations after meals at times.

Physical examination showed a pleasant, alert woman in no apparent distress and with normal coloring of skin, nail beds, and lips; moderate benign nervousness and apprehension; a weight of 139 lb. (63 kg.); and a height of 63 in. (1.532 m.). Her eyes were essentially normal except for mild sclerosis of retinal arterioles. There was mild chronic injection of the pharynx, mild abnormal redness of the tongue with low partially atrophied papillae, and one nontender small lymph node palpable in right upper anterior cervical group. The lungs were clear to percussion and auscultation; the heart beat was regular but rapid at 120 beats per minute, with tones of good quality and no murmurs; and the blood pressure was 172 mm. Hg systolic and 102 mm. Hg diastolic. A visible rounded mass was noted in the left side of abdomen, which on palpation felt firm but not hard and did not have a sharp definite edge (this subsequently proved to be an enlarged spleen). Pelvic examination was essentially normal except for mild senile vaginitis; the extremities and deep tendon reflexes were normal. The chest roentgenogram was essentially normal. A retrograde pyelogram showed good renal function and normally outlined kidneys, the left being separate from a large mass evident in the left flank and abdomen. The upper gastrointestinal roentgenogram series showed no abnormalities in that system and indicated that the mass in the left side of the abdomen was an enlarged spleen. Skull roentgenograms were normal. No abnormalities of the ribs, vertebrae, or pelvis were noted on the films taken. The electrocardiogram was normal.

The initial laboratory studies of venous blood showed the following results: hemoglobin 20.2 gm. (sodium carbonate and photoelectric determination), red blood cells 7,200,000 per cubic millimeter, white blood cells 5,700 per cubic millimeter, blood platelets from 29,000 to 74,000 per cubic millimeter, prothrombin time 26% of normal, nonprotein nitrogen 31.6 mg. per 100 cc., and sedimentation rate 0.5 mm. per hour (Wintrobe). The bleeding time was 20 minutes, and the coagulation time 6 minutes. The differential count of the blood smear showed: 20 to 28% segmented neutrophils, 46 to 55% staff form neutrophils, 13 to 17% lymphocytes, 1 to 5% monocytes, 1 to 2% blast forms, and 4 to 5% unclassified young white blood cells on several counts of 100 cells. The initial urinalysis showed specific gravity 1.012, pH 5.5, albumin 4+, no glucose, a microscopic rare white blood cell, and Bence Jones protein negative. At the time of pyelography the albumin was found in both kidneys. Smears from a sternal marrow aspiration were reported to show little true marrow tissue, a normoblastic erythroid hyperplasia, and no megakaryocytes. The operator had great difficulty in aspirating enough marrow to prepare an adequate smear.

Further questioning at this time in regard to the history revealed that the patient had borne four children without undue bleeding or other difficulty, and none of them had shown to date any abnormal bleeding tendencies; however, the patient stated that when she had had her teeth extracted 15 years previously (at age 45) there was excessive and prolonged bleeding of the gingiva for several days. Since that time she had noted the occurrence of easy bruising with ecchymoses appearing in the skin at times even without apparent trauma. Nosebleeds had also occurred spontaneously on numerous occasions. Ten years previously (at age 50) a perineorrhaphy had been done, and a perineal hematoma appeared postoperatively, which resulted in a sloughing of the sutures and failure of the repair. No enlargement of the spleen was noted at that time. Two years later the operation was repeated successfully without untoward bleeding or other incident. During the seven years prior to the present period of observation she had taken various medicaments more or less regularly for hypertension. Her local physician reported that these drugs were theophylline, aminophylline, phenobarbital, and Veratrite (a combination of veratrum viride, sodium nitrite, and phenobarbital). During these years no enlarged spleen had been noted at any time. She had not been examined between Feb. 20, 1947, and Sept. 14, 1948.

After the initial studies were completed the patient was treated with large amounts of synthetic vitamin K, rutin, ascorbic acid, and a polyvitamin preparation. After about a week of this treatment a recheck of the peripheral blood showed an improvement of the bleeding time to 5 minutes, coagulation time to 4 minutes, and prothrombin time to 70% of normal; the platelets had increased to 128,500 per cubic millimeter. A tourniquet test at the same time was strongly positive, and several small cutaneous ecchymoses were seen. The total serum protein was 7.03 gm. per 100 cc.: 5.22 gm. per 100 cc. albumin and 1.81 gm. per 100 cc. globulin.

A series of five small therapeutic exposures of x-ray over the spleen were then given without resulting in appreciable shrinkage in its size. This was thought to exclude the possibility of a lymphoblastoma of the spleen. Examination of the sternal marrow was repeated at this time. It was again difficult to obtain true marrow tissue. Examination of the smears showed myeloid and erythroid elements. There appeared to be some arrest of the myeloid elements at the metamyelocyte level. Some erythroid hyperplasia was present, and megaloblasts were seen. Examination of eight smears failed to reveal any megakaryocytes. A Congo red test was then performed, and 80% of the dye was retained on one occasion and 72% on recheck five days later.

Another test of the bleeding time gave a figure of 1½ minutes, of the coagulation time 6 minutes, and of the platelet count 152,200; a biopsy procedure was thought to be safe. A small left rectus incision was made, and the enlarged, rather soft purplish spleen was exposed and a biopsy specimen obtained. Splenectomy was not considered at this time because of the complete absence of megakaryocytes. A biopsy was also obtained from the liver, which appeared grossly normal. Microscopic examination of the liver tissue showed fatty meta-

morphosis. The spleen tissue showed distortion of the general architecture because of the presence of hematopoietic foci, including numerous megakaryocytes (fig. 1). A collection of hyalin material in one area was suggestive of amyloid but not typical of the usual picture of parenchymatous amyloid distributed about the central arteries and deposited within the malpighian bodies. The pathological diagnosis was myeloid metaplasia. A rib biopsy was also made. The rib marrow showed the general architecture of marrow, with no evidence of either amyloidosis or fibrosis. The operative wound healed normally in every respect. Treatment with rutin, ascorbic acid, and polyvitamins together with a high protein diet was continued.

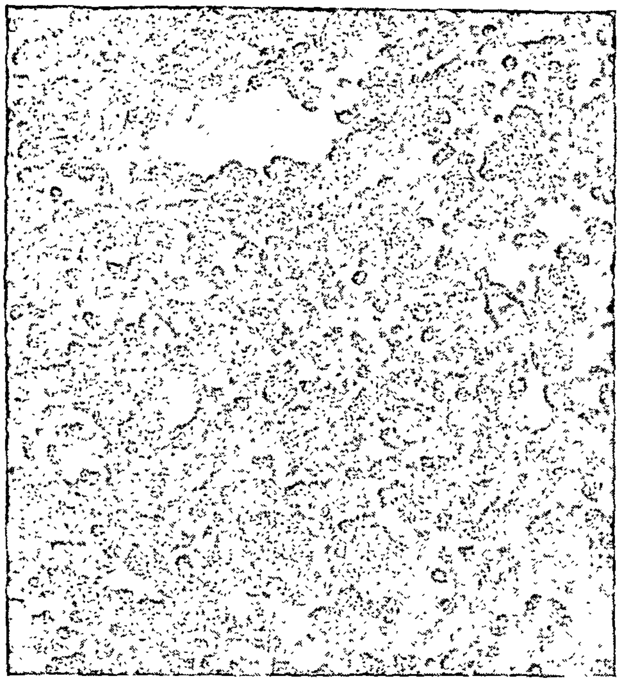

Fig. 1.—Biopsy specimen from spleen taken September, 1948. Note the megakaryocytes and hematopoiesis.

Three months later (December, 1948) the patient returned for reexamination. She stated that she felt improved with respect to her fatigue and general feelings. The weight was unchanged at 139 lb. The spleen was unchanged in size. Laboratory tests showed: hemoglobin 98% (16.5 gm.) (Sahli), red blood cells 5 million, white blood cells 8,800; blood smear, 68% segmented neutrophils, 2% staff form neutrophils, 28% lymphocytes, and 2% monocytes; platelet count 172,000; bleeding time 4 minutes; coagulation time 3 minutes 45 seconds. Quantitative test for albumin in the urine showed 1.8 gm. per liter. A sternal marrow biopsy was performed with a Turkel biopsy needle. Several plugs of tissue were obtained, and sections were made. These were reported to show a diffuse distribution of cells with little evidence of fat and absence of the usually encountered hematopoietic islands. There was suggestive evidence of hyalin material. Megakaryocytes were numerous but showed no platelet formation. The special amyloid stains were indefinite and not conclusive of the diagnosis.

The patient was seen again in March, 1949. The spleen was definitely larger. No enlarged lymph nodes were found. Laboratory tests showed: sedimentation rate 1 mm. per hour (Wintrobe); hemoglobin 102% (17.5 gm.) (Sahli); red blood cells 5,150,000; white blood cells 8,700, with 60% segmented neutrophils, 2% staff form neutrophils, 2% eosinophils, 32% lymphocytes, and 4% monocytes; bleeding time 2 minutes 45 seconds; coagulation time 9 minutes 40 seconds; and platelet count 276,000. Urinalysis showed specific gravity 1.020, pH 5, albumin 3+, and no reducing substances. The Congo red test showed 45% retention of the dye. The findings in June, 1949, were essentially similar to those already noted.

In September, 1949, she complained of some increase in fatigue, generalized "hurting" of the head, and mild mental fogginess. The laboratory findings were unchanged. The weight was 135 lb. (61.2 kg.) and blood pressure 156/90 mm. Hg. The spleen was definitely larger, the free edge now reaching to the umbilicus and left iliac crest. At this time there developed rather acutely an aseptic inflammation and edema of the right great toe with subsequent appearance of a necrotic ulcer on the plantar surface at the base. Priscoline (2-benzyl-2-imidazoline), rest, elevation, and plain sterile dressings were prescribed. The lesion healed completely in a few weeks. This was thought to be a vascular thrombosis. The laboratory and other findings were unchanged in November, 1949. She was hospitalized in January, 1950, for a mild case of acute bronchitis, which subsided in a few days. Penicillin therapy was begun. At this time the hemoglobin was 87% (13.5 gm.) (Sahli); red blood cell count 5,460,000; and white blood cell count 8,200, with 66% segmented neutrophils, 3% staff form neutrophils, and 31% lymphocytes. The nonprotein nitrogen was 36 mg. per 100 cc. The urine showed 2+ albumin. The chest roentgenogram showed some increase in bronchovascular markings.

Between January, 1950, and May, 1950, the patient noticed increasing weakness, fatigue, and anorexia. On May 5, 1950, she was admitted to the hospital because of persistent and uncontrollable nosebleed. A blood cell count showed hemoglobin 41% (6.6 gm.) (Sahli) and white blood cells 195,000, all classified as lymphoblasts. No mature neutrophils were seen on the entire slide (fig. 2). The urine was reported negative for albumin. In spite of blood transfusions, vitamin K, penicillin, and other supportive measures, the patient died on the third day.

The significant gross postmortem findings were reported as follows: 1. The spleen weighed 2,880 gm. The general configuration was not markedly changed from normal. The splenic notches were discernible. The capsule was smooth and glistening and showed numerous small pitted areas, ranging in size up to 0.5 cm. in diameter, and the surface was reddish-brown in color, showing a faint yellowish mottling. On cross section a dark reddish-gray slightly granular cut surface was present, in which the normal splenic markings were completely obliterated; however, a vague mottled pattern was seen in which the general basic reddish-gray color showed vague areas that were dark reddish-purple in color. 2. The liver weighed 1,680 gm. The external surface was smooth and glistening and a normal reddish-brown color. On cross section a granular reddish-brown cut surface was seen. A 2.0 cm. thin-walled cyst

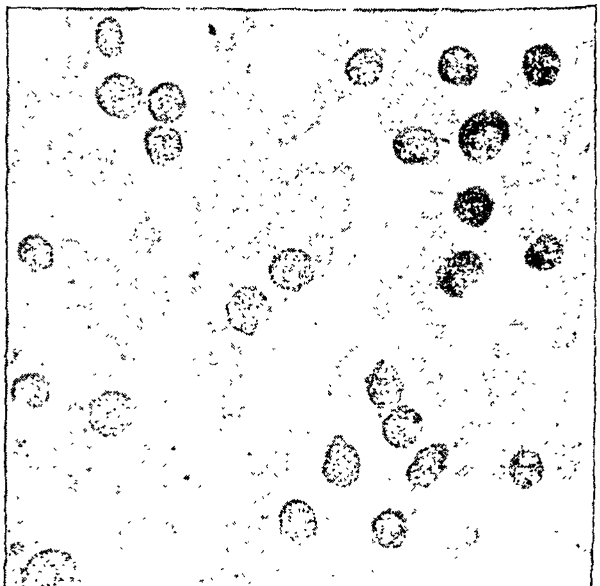

Fig. 2.—Smear of peripheral blood taken just before death in May, 1950. Note the numerous blast cells of myeloid origin.

filled with clear fluid was present in the lateral-most aspect of the right lobe. The right lobe also showed several worm-like streaks, which appeared to be either dilated bile canaliculi or dilated veins present on its anterior surface. These varied in size up to 0.1 cm. in diameter and measured as much as 2.0 to 3.0 cm. in length. They seemed to course immediately beneath the capsule. 3. The left kidney weighed 114.0 gm., and the right 122.0 gm. The capsule of each kidney stripped with moderate difficulty from a very granular pale pinkish-yellow to tan surface. On cross section the cortical-medullary demarcation was quite sharp. The cortex was pale tan in color and measured 0.7 cm. in thickness. The pyramids showed a rather marked paleness, and the pyramidal markings were less distinct than usual. There was no abnormality of the calices or pelvis.

Microscopic examination of tissue was reported as follows: 1. The general architecture of the spleen was completely replaced by a connective tissue stroma in which there were numerous leukocytic cells (fig. 3). These showed only a scanty amount of cytoplasm, and very few of them could be identified as to the cell type. Compared with the surgical material the appearance was quite different, the surgical material having been obtained in 1948. In this there were large numbers of megakaryocytes present. 2. The general architecture of the liver was fairly well preserved. The sinusoids obviously showed leukocytic cells, and in a few areas there were hematopoietic foci, none of which contained megakaryocytes. 3. In the kidneys there were a few small cortical scars. The tubular system was quite well preserved. The glomeruli all showed a variable degree of glomerulosclerosis with marked reduction in the vascularity. In the majority of instances there was a hyalin-like material deposited beneath the capillary walls not associated with inflammatory cell infiltration. There was no evidence of crescent formation and very little evidence of thickening of Bowman's capsule. In some instances the glomeruli contained a few rounded hyalin masses, but this was not a common finding. The arterioles were thick-walled and often showed hyalinization. A few of the medium-sized arteries showed hyalinization but very little endarteritis obliterans. There seemed to be no interstitial deposition of any hyalin material. Stains of the kidney with Congo red and crystal violet for the demonstration of amyloid were made and showed no evidence of amyloid. 4. Section of the rib showed that the normal bone marrow was almost completely replaced by leukemic cells. 5. Several lymph nodes showed foci of leukemic infiltration but not of hematopoiesis. Klatsch preparations of bone marrow showed that the majority of cells were blast forms but were associated with cells of the myeloid series; hence it was assumed that the cells were mostly myeloblasts. A review of the peripheral blood smear that was made during the patient's life also shows that the majority of these were blast forms and were probably myelogenous instead of lymphogenous.

COMMENT

The end-phase of this case as indicated by the peripheral blood with marked anemia, thrombocytopenia, and a very high white blood cell count with almost 100% blast forms, as well as the evidence of leukemic infiltration into the bone marrow, lymph nodes, spleen, and liver, seems to be indistinguishable from myelogenous leukemia. However, during the intermediate phase of 20 months' direct observation there was more or less polycythemia, a normal or slightly leukemoid picture of the white blood cells in the peripheral blood, apparently myelofibrosis, no evidence of leukemic infiltration of any organs, and characteristic myeloid metaplasia of the spleen. We thought that we were dealing with a typical case of agnogenic myeloid metaplasia until the change in the peripheral blood appeared during the last days of the patient's life. Primary amyloid disease was considered for a time because of the marked albuminuria without other evidence of nephritis, the positive Congo red test, difficulty in aspirating cellular elements from the bone marrow on repeated attempts, and the suggestive hyalin material in the original biopsy of the spleen. Subsequent events and findings caused us to discard this diagnosis.

The medical literature of the past 10 years indicates a difference of opinion as to the relation of agnogenic myeloid metaplasia to leukemia. Block and Jacobson [1] in their excellent review of the subject and Jackson, Parker, and Lemon [2] earlier indicate that, while myeloid metaplasia is a syndrome of varied cause, it is to be sharply distinguished from leukemia because of the apparent marked difference in prognosis and treatment.

The case presented here certainly qualified as one of agnogenic myeloid metaplasia for many months and was treated as such, but we could hardly avoid the diagnosis of leukemia after making the terminal clinical and necropsy observations. We call attention particularly to the marked change in the microscopic appearance of the sections of spleen taken at necropsy from those taken at biopsy 20 months earlier. Practically all evidence of myeloid metaplasia had disappeared, and there was a diffuse fibrosis and leukemic infiltration at the time of necropsy.

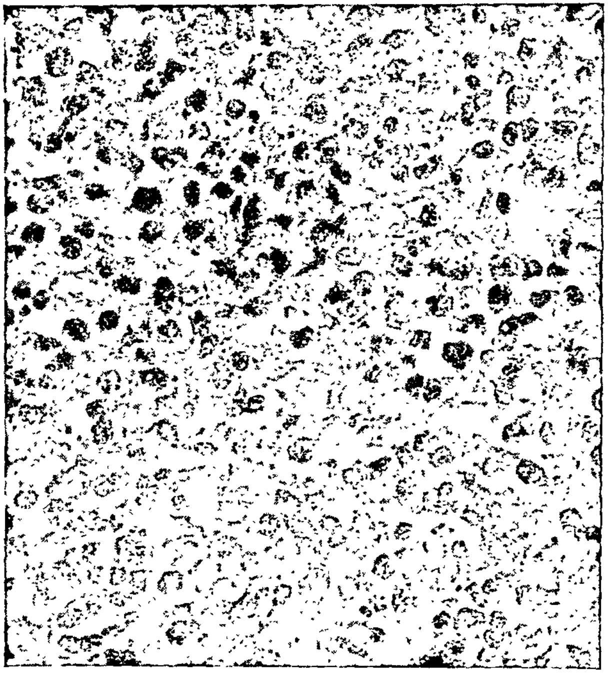

Fig. 3.—Postmortem specimen from spleen in May, 1950. Note the rare megakaryocytes and replacement of general architecture by leukocytic cells on connective tissue stroma. Compare with biopsy specimen taken September, 1948.

One of us (J. R. S.) has not uncommonly found patients with a full-blown leukemia who seem to have an unusually dense marrow cavity, in which difficulty is encountered in aspirating any cellular elements, and others in whom there has been practically no infiltration of any of the parenchymatous organs, the only major involvement being the bone marrow and the blood. In some instances even the peripheral blood shows very little change.

2. Jackson, H., Jr.; Parker, F., Jr., and Lemon, H. M.: Agnogenic Myeloid Metaplasia of the Spleen: A Syndrome Simulating Other More Definite Hematologic Disorders, New England J. Med. **222**: 985-994, 1940.

We do not hope to resolve any controversies about the fundamental nature of myeloid metaplasia or of leukemia on the basis of this one case. We present it simply as an unusual case of apparent leukemia with an early course, which was like that described for agnogenic myeloid metaplasia. After all, not many cases of leukemia are observed from a time before their apparent onset till their final termination. Perhaps this will serve as some evidence of what leukemia may be like in its earliest stages and perhaps some evidence of what may happen ultimately to some cases of agnogenic myeloid metaplasia.

SUMMARY

The case of a 60-year-old white woman is presented who showed the characteristic findings of agnogenic myeloid metaplasia during a period of about 20 months' observation and then the characteristic findings of leukemia just before death and in the postmortem studies.

NEAR FATAL REACTION TO SULFOBROMOPHTHALEIN (BROMSULPHALEIN) LIVER TEST

Leon V. McVay Jr., M.D., Memphis, Tenn.

The determination of sulfobromophthalein (Bromsulphalein) retention is one of the most commonly employed hepatic function studies. Its importance in the diagnosis of liver disease is generally recognized. This procedure has been designated, and is widely regarded, as the most valuable of the excretory tests of liver function.[1] While several mild allergic reactions to sulfobromophthalein have been reported, only a few serious effects have been observed.[2] The purpose of this paper is to describe a near fatal reaction to this laboratory procedure and to suggest certain precautions in its use.

REPORT OF A CASE

A 68-year-old Negro man was observed in the antibiotic clinic of the John Gaston Hospital and the University of Tennessee College of Medicine on April 28, 1952. Since Feb. 17, 1949, this patient had been observed by the general medicine clinic because of arteriosclerotic heart disease, with cardiac insufficiency. Medication had consisted of digitalis, ammonium chloride, low sodium diet, and occasional administration of mercurial diuretics. There was no personal nor familial history of allergy.

On Jan. 14, 1952, this patient was selected as one of 450 geriatric patients who were being studied with regard to the effect of prophylactic antibiotic therapy on intercurrent infections. As a portion of this investigation, a series of hepatic function determinations, including the sulfobromophthalein test, were carried out at regular intervals. The test was performed on Jan. 14, 1952, with 10% retention at 45 minutes. No untoward side-effects were caused by this procedure.

On April 28, 1952, 5 mg. of sulfobromophthalein per kilogram of body weight was again injected intravenously. Approximately three minutes were required for the administration of the dye. As the needle was being withdrawn, the patient complained of dyspnea and became quite apprehensive. He described a severe choking sensation and, in two to three minutes, was covered with cold perspiration. In addition, the patient complained of generalized pruritus of extreme severity and, while no epigastric or abdominal pain was present, vomited twice. In less than five minutes, the cardiac rate increased from 94 to 136 per minute. The blood pressure, which had been recorded as 110/82 mm. Hg 15 minutes prior to the intravenous injection, dropped to 72/64 mm. Hg 5 minutes after the dye had been administered and was 68/48 mm. Hg shortly thereafter. A comatose state rapidly developed. Pulmonic examination revealed a few inspiratory rales in the bases of both lungs.

The patient was immediately placed on an examining table in the clinic, his feet were elevated, and oxygen was administered by nasal catheter. Five-tenths of a milliliter of epinephrine hydrochloride in 1:1,000 solution was injected subcutaneously with no apparent result; injection was repeated using 0.3 ml. at five minute intervals on four occasions. Despite the injection of epinephrine, the blood pressure, 15 minutes after the onset of the episode, was 56/40 mm. Hg; however, within 30 minutes it had increased to 78/64 mm. Hg. The comatose state persisted for approximately 30 minutes; for an additional 10 to 15 minutes, the patient was disoriented as to time, person, and place. Approximately two hours after consciousness was regained, the blood pressure was 112/68 mm. Hg. The patient was, however, extremely weak and was admitted to the medical service of the John Gaston Hospital for observation.

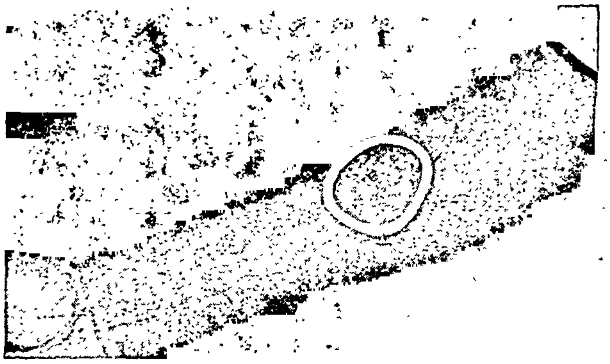

Fig. 1.—Intradermal reaction to sulfobromophthalein 10 minutes after injection. Area of erythema measures 4.5 by 6.5 cm.

On hospitalization, the only complaint was weakness; extreme apprehension also persisted. Physical examination revealed no pertinent findings. The white blood cell count was 26,100 per cubic millimeter, with 84% polymorphonuclear leukocytes and 16% lymphocytes. Four hours after admission, a low grade fever developed and persisted for 24 hours. It reached a maximum of 100 F (37.8 C). Serial electrocardiograms were not revealing, and peripheral blood values returned to normal in 72 hours. The patient was discharged from the hospital on the fourth day in an asymptomatic condition and with no evidence of sequelae.

On his return to the antibiotic clinic, it was decided to omit the sulfobromophthalein determination from his future studies; however, on Jan. 15, 1953, an intradermal skin test was carried out. Sulfobromophthalein was diluted with equal parts of isotonic sodium chloride solution, and 0.1 ml. of this mixture containing 2.5 mg. of the dye was injected into the volar aspect of the right forearm. Sodium chloride solution alone was injected into the left forearm. Within 10 minutes, an irregular area of erythema was present on the right forearm; this measured 6.5 by 4.5 cm. (fig. 1). Furthermore, the patient noted minimal dyspnea and a slight choking sensation that persisted for 5 to 10 minutes. Aside from mild localized pruritus at the site of the lesion, nothing else was observed. No change was apparent about the site of the control injection. During the ensuing two days, the reaction around the intradermal injection of dye increased progressively and reached maximum

J., Jr.: Unusual Toxic Reaction to Bromsulfalein, Ann. Int. Med. 34: 1265-1269 (May) 1951.

intensity at 48 hours (fig. 2). At that time, the entire right forearm was greatly swollen. The diameter of the midportion of the right arm was 11.5 in. (29.2 cm.), while that of the left arm was 9.5 in. (24.1 cm). The involved area measured 24.5 by 13.5 cm., was erythematous and slightly tender, and was surrounded by an irregular serpiginous border. Necrosis occurred at the location of the injection. Tender axillary and epitrochlear adenopathy was present. For three days, the patient noted a slight bitemporal headache, with associated malaise. A low grade fever fluctuating from 99 F (37.2 C) to 99.8 F (37.7 C) was also present during this period. Gradual remission began after 48 hours, while return to normal required seven days. No medication was administered.

COMMENT

Since its introduction by Rosenthal and White in 1924,[3] the sulfobromophthalein test has undergone several modifications. In 1925, its originators recommended the intravenous injection of 2 mg. of dye per kilogram of body weight, with a blood specimen being obtained after 5 and 30 minutes.[4] Mateer and his associates [5] suggested that 5 mg. per kilogram of body weight be employed in order to furnish a more adequate test of hepatic reserve. Later investigators emphasized the value of increased retention of sulfobromophthalein in establishing the diagnosis of chronic hepatitis in the absence of jaundice.[6] Its importance in detecting early cirrhosis has been frequently demonstrated.[7] Recently, a significant correlation between the degree of sulfobromophthalein retention and diffuse liver cell damage was reported.[8] It is now generally recognized that retention of more than 6% of the dye 45 minutes after the intravenous injection of 5 mg. per kilogram of body weight is indicative of liver cell damage. The test, however, is of value only in the absence of conspicuous jaundice.

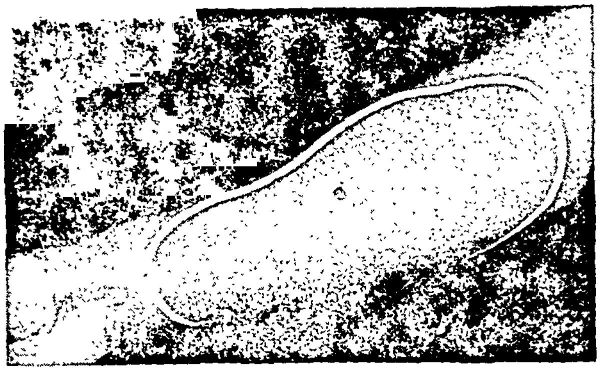

Fig. 2.—Intradermal reaction to sulfobromophthalein injection at 48 hours. Necrosis is present at the site of injection. The area of involvement measures 13.5 by 24.5 cm.

At present, the sulfobromophthalein test is one of the most commonly employed hepatic function studies. Several factors have contributed to its widespread popularity; the dye is soluble, its solution is rather stable, it is not overly irritating to the tissues, and it is only very rarely a cause of venous thrombosis. In 1950, Greene [1] concluded that sulfobromophthalein had generally become recognized as the substance of choice as an excretory test of hepatic function.

While occasional mild allergic manifestations have been noted with this test, the first severe toxic reaction was not observed until 1946,[2a] when an acute allergic response occurred in a patient known to have bronchial asthma. Another serious reaction was observed in 1951.[2c]

The case described in this paper emphasizes the potential danger of this laboratory procedure. It would appear that, if a patient has previously been subjected to a determination of the sulfobromophthalein retention, an intradermal test should be carried out before it is repeated. This would seem to be especially indicated if there is a history of allergy. In all instances, the dye should be administered cautiously over a period of at least five minutes.

SUMMARY AND CONCLUSIONS

A near fatal reaction to the sulfobromophthalein (Bromsulphalein) liver test is described. The case reported provides evidence that this widely employed laboratory procedure is not entirely innocuous. Certain precautions in its use are recommended.

TWENTY PER CENT CARBON DIOXIDE INHALATION IN MUSCULAR RIGIDITY

INDICATIONS AND CONTRAINDICATIONS

Temple Fay, M.D., Philadelphia

Inhalation of a mixture of 20% carbon dioxide and 80% oxygen as a diagnostic and therapeutic measure in certain types of rigidity and manifestations of dystonic disorders has been used for the past 12 years. In view of the sudden and rapid adoption of this procedure by physicians and physical therapists for certain neuromuscular types of dysfunction, popularly known as "cerebral palsy," a brief survey of the basis for the use of this procedure, of its presently known values, and of definite contraindications to its use is in order.

Since the report in 1952 of clinical observations [1] on the use of this procedure, various reports of success or failure with this method have appeared in this country and abroad. It must be realized that, as yet, the physiological bases for the surprising and often startling changes that immediately occur, and often are sustained, are poorly understood; therefore, promiscuous use of the method by any other than enlightened medical advisors or skilled anesthetists is to be deplored. Final evaluation of the method can rest only on critical analysis of large series of patients. It is not the purpose of this communication to deal with the detailed study and background that led up to the clinical use of 20% carbon dioxide inhalation for certain carefully selected types of neuromuscular involvement, much of which has been reported elsewhere or remains to be published. A sketch of the background and basis for the use of this method is, however, appropriate for the sake of orientation, as are remarks on its possible effectiveness as an adjunct to the present therapeutic methods.

[1] Fay, T.: Effects of Carbon Dioxide (20%) and Oxygen (80%) Inhalations on Movements and Muscular Hypertonus in Athetoids, Tr. Am. Neurol. A., 1952, p. 225.

BACKGROUND

It has long been known that certain manifestations of rigidity in postencephalitic and decerebrate states or of rigidity of mixed origin disappear during sleep, with relaxation and even cessation of repetitive gross tremors and movements. A similar state ensues during periods of restful relaxation in certain well-known, clinical types of torticolis. The question arose about 12 years ago why these desirable periods of freedom from the distressing tonic and hyperkinetic states should occur, even though it has long been recognized that the pathological condition in the central nervous system is a fairly constant and fixed process. At first it was assumed that "sleep," with its indefinable physiological qualities, was responsible for this neuromuscular relaxation state. It was obvious that, if the patient could be given appropriate therapy and treatment during such relaxed phases, much might be accomplished in the training of better control of finger, hand, arm, leg, neck, and facial movements. In other words, if the qualities of consciousness and activity could be retained and at the same time the relaxation present during sleep maintained, many benefits would be obtained through corrective therapy.

Close clinical study of the problem indicated that respiration was involved in some direct manner and that hyperventilation was present during the active periods of wakefulness (i. e., crying, movement, and explosive speech). It was felt that this factor, superimposed on the primary disease of the nervous system, might lead to accentuation of undesirable symptoms during conscious periods. This clue suggested the possibility that hyperventilation, with its known hypertonic effect on muscle tone (tetany) and its tendency to produce alkylosis (loss of carbon dioxide), might be an important factor.

Momentary correction of chronic carbon dioxide lack was considered as a possible diagnostic measure to evaluate the muscular effects of carbon dioxide deficiency (hyperventilation component) in order to distinguish between the effects of this phenomenon from the intrinsic neurological alteration of function arising from the central lesion. The vasodilator effects of carbon dioxide on cerebral vessels, noted by Schmidt, and the psychomotor relaxation states produced by inhalation of 10% carbon dioxide, observed by Meduna, led to the selection of a 20% concentration of carbon dioxide for use in this procedure. It was found that this concentration is sufficiently intense to produce a physiological effect without producing loss of consciousness. When levels of 25 to 30% or higher are administered, loss of consciousness may ensue.

Eight years ago, it was repeatedly observed that inhalation of a mixture of 20% carbon dioxide and 80% oxygen for one to three minutes by patients manifesting true rigidity produced immediate and surprising reduction in muscle tone and facility of movement, with a tendency toward a smoother more coordinated type of response than had previously occurred with any other procedure or drug. After this procedure, the patient was capable of understanding and responding to commands, often could perform many movements formerly impossible for him to perform, and had better use of the muscular structures during the short period of inhalation. It was anticipated that the effects of this procedure would be only diagnostic (to confirm the presence of true rigidity as distinguished from spasticity), and that the response would be only temporary. The surprising clinical result was that the effects in many instances persisted as long as three weeks after a single inhalation, with striking alteration in the previous neuromuscular tone and response.

The effects and details of this response and the explanations for it have been studied over the past four years and have been reported elsewhere.[2] Particularly interesting was the question of why the brief inhalation of concentrated carbon dioxide should produce a sustained clinical state of improvement, even though the pathological process was known to be chronic or more or less fixed. No adequate or acceptable physiological explanation has been established, although discussion and speculation are increasing. Yet, the fact remains that improvement has been sustained in patients with certain types of disease for periods exceeding three years, when fortified by the appropriate physical therapeutic measures now available. One inhalation episode or subsequent episodes given weekly, monthly, or even semiannually have altered the previously distressing state to the satisfaction of the patient and the clinician, even though long established structural alterations that require orthopedic correction remain. Increase in facility of movement and sustained states of relaxation have made possible self-feeding, walking, better speech expression, and additional self-care, which formerly were impossible, and these favorable changes have been noted not only in infants and children but also in young adults and, to some degree, in older persons.

INDICATIONS

In my experience, the best results have been obtained in cases of the true types of rigidity (Parkinsonian and athetoid), and these must be clearly differentiated from the spastic and other structurally handicapping types. Currently, the clinical manifestations used to distinguish the rigidity group are a hypertonic state of the muscles in which, in the absence of fixation or chronic contracture, there is a slow sustained resistance of the muscles to stretch, often described as "lead pipe" rigidity, or a more jerky form of resistance of the muscle to stretch, commonly known as "cog wheel" rigidity. When there is impairment of coordinated movement or postural fixation of the extremities due to hypertonic muscular states, a so-called paralysis (paralysis agitans) results. In many athetoid patients and patients with postencephalitic parkinsonism, intellectual abilities are not impaired, even though expressive motor facility may be greatly altered. The relaxed states obtained with carbon dioxide inhalation are of real benefit to patients in this group, because muscular responses formerly impaired are more easily augmented by properly directed physical therapy and muscles formerly "frozen" can thus be utilized.

---

[2] The reports, which are to be published, were read before the Danish National Society of Physical Medicine, Copenhagen, 1951; the American Neurological Association, Atlantic City, N. J., June, 1952; the American Academy for Cerebral Palsy, Durham, N. C., October, 1952; and the Orthopedic Club, Philadelphia, March, 1953.

It became obvious that an increase in endogenous carbon dioxide from metabolism of carbohydrates or alcohol or from an increase in the volume of residual air in the chest, as well as an increase from carbon dioxide inhalation, improves neuromuscular function, and these longer acting adjuncts were added to the therapeutic armamentarium. Patients who manifested relaxation during sleep and who responded favorably to the carbon dioxide inhalation test were placed on maintenance regimens, which include regular breathing exercises to increase the chest volume and residual air component, and holding the breath with proper exhalation, which, in turn, improves carbon dioxide metabolism, so that the patients may retain a state of increased carbon dioxide availability at all times.

CONTRAINDICATIONS AND PRECAUTIONS NECESSARY

The clinical response, although great in some patients, was slight in those who had neuropathological lesions or contractures of muscles and tendons, who did not cooperate, or in whom alteration of the carbon dioxide factor was not possible. Nevertheless, word of the value of the procedure has been spread so rapidly by persons who have been helped that little attention has been paid to the failures that occurred or the contraindications to its use.

Inhalation of 20% carbon dioxide and 80% oxygen should be used chiefly in patients with rigidity, although it should be realized that patients with some other conditions (such as those with the spastic, mixed, and as yet unclassified dystonic disorders with lack of coordination) may show a favorable response. No benefit whatever can be expected in patients with intrinsic, fixed, pathological lesions in whom normal relaxation does not appear during sleep or during the inhalation test.

It is important that the gas mixture used be pure. Some easily obtainable commercial forms of concentrated carbon dioxide retain irritative by-products and chemical agents from the production process. If used, such forms must be purified. Carbon dioxide used in ordinary hospital anesthesia may be used. Irritation, coughing, and spasm may result from use of the impure material.

Hyperpnea occurs during carbon dioxide stimulation of respiration. It is, therefore, highly important that the patient be carefully examined for disease of the lungs or chest in which temporary overexpansion may cause stretching, rupture, or tearing of adhesions. Careful cardiac studies and blood pressure determinations should be made before administration of the mixture, because holding of the breath, alterations in heart function, and some hyperkinetic movement arising during the procedure may lead to undesirable cerebral involvement. As yet, these complications have not occurred in my series, but if the mixture is carelessly administered, without proper medical and anesthetic supervision and if the proper precautions are not taken, they could easily occur. In the presence of an aneurysm, extreme arteriosclerosis, or a progressive brain lesion, which only careful neurological study can rule out, the procedure is definitely contraindicated. The usual postanesthetic care and observation of the patient must be maintained for at least a few hours. Finally, it must be remembered that the 20% carbon dioxide inhalation test should be considered a diagnostic procedure by which the degree of muscular rigidity can be shown and the indications for medical and physical therapy established.

BASIC MECHANISM

At present, it is possible to offer only a suggestion of what carbon dioxide inhalation may accomplish. It is obvious that it can in no way alter the primary neuropathological condition. Whatever effect it has must be secondary to some profound change in cellular function, caused either directly or indirectly by the gas itself. It is possible that a high local concentration of carbon dioxide would result in a shift of the pH to a more normal value, even though temporarily, or that carbon dioxide acts indirectly on some intrinsic cellular function that still exists within the nervous system and is capable of response. In my opinion, it is reasonable to assume that chronic hyperventilation states exist during the waking hours and in some way impair the function of the remaining neurological units that govern muscle response and activity either at the peripheral or at the central level. (One cannot escape the possible consideration that the respiratory cycle of so-called sleep is a more primitive and automatic mechanism than the modifications of inhalation-expiration that arise during awakened states.) It is possible that electrodynamic factors (cellular polarity and function) are altered when carbon dioxide in high concentrations shifts the pH sufficiently to produce action similar to that of acid in a storage battery. As a result, single cells or groups of cells would extend their functional activity to control wider neurostructural areas at beneficial levels. This mechanism would be analogous to that of the dial telephone, which, as a single unit, is capable of setting up a series of action currents or of connecting stations along a single hook-up. Thus, these cells are made capable of affecting a larger organized group of cortical or basic units, and finally neuromuscular activity is modified in its peripheral manifestations.

Obviously, this concept must be subjected to rigid further analysis, but it serves at the moment to explain an improvement in expressive function, even in the presence of deficient central control. That a single cell or fiber can function to carry a variety of impulse cycles is already recognized. It is possible that neural basal ganglion cell units, limited to almost a single activity or to insufficient activity by local disease or by metabolic neurodynamic functional loss due to chronic carbon dioxide lack, can be restored by repolarization to more normal levels of activity, i. e., to the handling of an increasing number of component cortical factors to an increasing degree. It is possible, also, that this increased activity may take the form of better neuromuscular response.

SUMMARY

It has been observed and is now fairly well established that brief inhalation of a mixture of 20% carbon dioxide and 80% oxygen in certain patients manifesting true rigidity produces prompt neuromuscular relaxation and changes in movement facility. It is believed that such a state, often seen in these patients during sleep, is due to a better metabolic adjustment to carbon dioxide. In the awakened state, chronic hyperventilation and carbon dioxide lack result in superimposition of hyperventilation phenomena on the effects of the original lesion, which becomes apparent as grossly incoordinated movement, neurointrinsic tremor (arising from neural units or levels, as distinguished from muscular, metabolic or emotional types), and hypertonic rigid muscular states (tetany). It is believed that sustained alteration is possible in patients in whom the inhalation test has shown that relaxation may be obtained, and maintenance therapy is given to correct the carbon dioxide deficiency directly or indirectly.

There are important contraindications to the promiscuous use of this procedure, which requires further observation and clinical analysis. It is important that it is recognized that, in patients in whom relaxation does not occur during the observed "sleeping period" or in whom a definite response is not observed during or after the inhalation test, the further therapeutic use of this procedure will be of little value. Therefore, such therapy should not be instituted without full realization of its limitations. When favorable test responses occur, prompt advantage of this temporary phase should be taken by active physical therapy measures and enhancement of body facilities for carbon dioxide elaboration and retention. the presence of coincident thoracic, cardiac, or cerebral disease must be ruled out before the test is administered.

Finally, the same careful care and control of the method must be maintained as has already been established for administration of any gas anesthetic. Judgment of the value of the procedure must rest on wider clinical experience, and explanations for its apparent beneficial effects must await further neurophysiological analysis.

8800 Germantown Ave. (18).

Radioisotopes.—There has been developed . . . an extension [of use of radioisotopes] which goes one step beyond pure mechanical placement. . . . It demands that an organ of the body do some metabolic work in achieving the end localization. . . . Many isotopes have been tested for their metabolic pattern in tumor tissue. . . . Some give no localization; some localize in critical tissues, some give fair localization but have poor energy characteristics. Others have the wrong half life. There was one rare example and probably no other simple element will be found which matches the promise of radioiodine. . . . The future usefulness of the metabolic positioning of radiation depends wholly upon research in basic tumor chemotherapy. . . . Most ideas in tumor chemotherapy have been complete failures. It is to be expected that most of our present and future ideas will also fail; but if one ever is successful, there are about 30 radioisotopes which have good radiation characteristics and may be attached to the molecule. Even though it has been a continuous source of disappointment, in this sense the metabolic placement of radiation is still the greatest challenge in the field of therapeutic radioisotope research.—M. Brucer, M.D., Encouraging and Discouraging Research with Therapeutic Radioisotopes, *Journal of Kentucky State Medical Association,* June, 1953.

SPECIAL ARTICLE

ORGANIZING A HEALTH MUSEUM

SUGGESTIONS BASED ON CLEVELAND HEALTH MUSEUM EXPERIENCE

Deac Martin, Cleveland

Although our country's health consciousness is widespread, it is not uniform. In some communities it is spread more thinly than in others. In either case, a health museum can be a rallying point for what already exists in community health projects, and beyond that it can be an instigator of new projects that will thicken, lengthen, and strengthen health consciousness by interesting more persons in guarding and improving their personal health.

This paper about health museums is written for physicians who agree that the medical profession is the natural leader in health education and who may be seeking means to live up to this responsibility and privilege. The conclusions reached are derived from association with the Cleveland Health Museum since it was a nebulous idea in 1939, three years after its incorporation by three members of the Academy of Medicine of Cleveland, its secretary, and the secretary of the Cleveland Health Council. Lacking precedent, these men had faith but no actual knowledge of what might be the future developments. As it has turned out, the original objectives are as sound today as they were in 1936, but methods of reaching them go beyond the founders' conceptions. Conclusions learned along the way by trial and error can furnish pointers, though not a pinpointed plan, for establishment of health museums elsewhere.

As evidence of national interest in health education, among the 1952 visitors who came to the Cleveland Health Museum from every state and 27 foreign countries, a satisfying number asked about ways to start a comparable project. The fact that these persons were impressed enough to want to "do likewise" is a good indicator. Others, especially foreign physicians, were at the museum to study the pioneering project in order to report on this means of mass health education. In addition to these personal contacts, the museum receives letters; the following excerpt of one such letter, dated in mid-1952, is typical: "I think our city needs a health museum but I do not know what to do about it, whether the county medical society, the county health forum, the city manager, or what person or group should be approached. Is it approved only by Protestants . . .?" Answering the direct question first, Director Bruno Gebhard assured the writer that all denominations utilize the museum and that its department of education, directed by Dr. Winfield G. Doyle, works closely with parochial as well as public school systems. No direct answer could cover the implied question about which local group should be approached to pilot a health museum move-

Public Relations Consultant to Cleveland Health Museum since its inception.

ment, because conditions vary widely in different cities. Any of the persons or groups mentioned, or others, may be successful as the bellwether.

FIRST STEPS

The feeling "we ought to do something for our town" is widespread enough to furnish evidence that some of the seed sown by the Bureau of Health Education of the American Medical Association and by localized medical groups has taken root. Education by special interest organizations, of which the National Tuberculosis Association is an early example, and by basically commercial organizations, such as life insurance companies, has constituted part of the movement. The bureau has pointed to the advertising of citrus fruit as an accelerator to the burgeoning national interest that is back of the financial support of health organizations and foundations by popular contribution.

Among the out-of-town persons and groups seeking methods at the Cleveland Health Museum have been representatives of the Minneapolis Junior Chamber of Commerce; the County Medical Society of Los Angeles; the Pittsburgh Junior League; the Lankenau Hospital, Philadelphia, which will receive further comment later; a banker from Sacramento, Calif.; a registered nurse from Kansas City, Mo.; and interested persons, including physicians, from the British Isles, Australia, China, Ceylon, and Quebec. The first such investigation in the early 1940's resulted in the health museum at Mexico City; next came one in Colombia, South America, and the Dallas Health Museum, which was launched by the Dallas Academy of Medicine and the county medical society in an attractive gray stone building well suited for museum use on the Texas state fair grounds. Medical and public health exhibits, such as those in the Buffalo Science Museum, the Toledo Museum, the Museum of Science and Industry in Chicago, the Army Medical Museum, and in institutional museums, such as that in the Mayo Clinic, in some cases are integrated into already established institutions whose primary interest may not be health education. A health museum need not be an unrelated unit. Also, the physician knows best that all of mankind's physical giants started from tiny embryos, and even a store window of health exhibits is a start.

Basically, a health museum stands on a tripod consisting of (1) space, (2) finance, and (3) a program. The three need not be considered in that order; for example, under "financial angels" below, finance is assured ahead of space or a program.

Financial "Angels."—1. An "angel," rather than the stork, could bring the baby into being through a large single gift, probably as a memorial. Naturally, such a giver may have ideas on how the gift is to be utilized. It is possible that the donor has a specialized interest, usually owing to some intimate experience, and wants the program centered around that main interest. If health education in the community may be aided by a main exhibit or hall devoted to diabetes, poliomyelitis, or the heart, for example, with a periphery of other helpful subjects, why should this not be done? 2. Perhaps several leading industries with employee health problems may finance the project. The acceptance and utilization of any large gift should be safeguarded, community health-wise, by a board of trustees, which should include physicians with the interest and time to see that the teachings are sound.

Professional Sources. — 1. The museum may spring from group activity and financing by the local medical society. In such a case, it is reasonable to assume that several physicians may find several patients willing to contribute and that the financial burden will not rest entirely on the society's members. Yet, if started in a small way, it may well be done without outside assistance. Costs will be discussed elsewhere. 2. The physicians may bring a health museum into being by working with some already established agency, such as the city health department or a health council or its equivalent.

Physical Equipment Approach. — Early activity may center around a building or space available. A well-endowed hospital may furnish space, or build a wing, while the physicians would provide the financing of exhibits and the program. The hospital may furnish space and finance the entire physical project, while the physicians furnish the program.

Community Approach.—The physicians could become the nucleus of a civic organization organized along Community Chest lines for fund raising. In the old days, the physician was the local public health authority and center of community health activities. In furnishing the spark to ignite public interest in a new health museum, the physician would reinstate himself in his old role. Funds could be raised from the public by means of memberships or contributions or both. "And why not?" queries Dr. Gebhard, "The artists do not build, equip, and furnish an art museum!"

There are other ways to get started, depending on local conditions, and combinations of several or all of the methods described are possible. Whatever the start may be, it is most desirable that the project be tied closely to widely respected physicians to impress the public with the authenticity of the information center and as evidence of professional interest in preventive medicine.

The first steps, therefore, consist actually of sales work, the convincing of key persons best able to be helpful. If the project should develop along lines calling for widespread support, the sales job may become comparable to door-to-door selling; lay committee members could canvass the community with Community Chest techniques. Thus far, Cleveland Health Museum has not gone to the public for support other than through the work of a membership secretary, quite different from an organized, high-powered "drive." The museum has grown in relation to performance, a natural growth. This aspect may differ in different communities, but, in general, it is safest to promise financial supporters less than is actually delivered. Originally, the Cleveland museum membership was almost entirely composed of physicians and dentists. Lay membership has multiplied five times since 1940 and now stands at about 1,300, compared with 800 physicians and dentists. The lay membership developed mostly from the personalized approach. Members of the board of trustees in some cases have even made their Christmas card lists and, of course, the use of their names available to the membership secretary.

FINANCIAL ASPECTS

Costs and financing of a health museum, initiated by any of the means already described or by others, cannot be blueprinted in this general comment. A project fortunate enough to have a home, upkeep, and perhaps some personnel offered to it at the beginning is in a quite different position than one that must consider these fundamentals along with the added financing of exhibits and a program. Nevertheless, we do have an indicator. When it opened in November, 1940, Cleveland's health museum had a home, a reasonably sure income of about $8,000 from physicians, dentists, and others who had pledged $10 annual memberships when and if opened, and a 1941 budget of $25,000 for which there was no guiding American experience. That first budget equalled about what a state society would pay today for one motion picture with sound.

The 1952 budget was $103,000 in round numbers. Because of the need for additional space, especially larger lecture hall facilities, and because of programs that would be possible through instigation by the museum and by unexpected requests from other sources, the 1952 budget appears less adequate to me than did the original one when we had nothing with which to make comparisons. This is not a statement of frustration but one indicating experience, and it serves to point up Dr. Gebhard's statement that stems from museum experience both in this country and in Europe: "A good museum is never finished." The moral to some local group, thinking in terms of a place for visual health education over a period of years, is obvious. The following tabulation shows the highlights of the 1941 budget, which the individual local groups might divide or multiply by whatever figure changes $25,000 into a realistic amount for the local situation; it is shown in comparison with the 1952 budget:

	1941	1952
Administration	$12,000	$ 22,000
Operations	4,800	21,000
Promotion-membership	3,700	16,500
Exhibits	4,200	27,000 *
Education	300	16,500
	$25,000	$103,000

---

* Includes building exhibits for others.

The 1941 budget was predicated on a schedule in which the museum was to be open 6 hours daily on week days and 2 hours on Sunday, a weekly total of 44 hours. In 1952 the museum was open 59 hours weekly. Sunday is the big day in attendance. Nights are preferred by some groups and, to a lesser extent, by some persons. The greater the number of hours open, the higher will be the light, heat, maintenance, and upkeep bills. It is wise to feel the pulse of the community and try to set the open hours for a theoretical steady flow rather than for peaks, when crowds can be so great that the visitors do not have opportunity to absorb what they see. A board of trustees can point with pride to large attendance figures, but a more important criterion of success is the degree to which misinformation is eradicated and replaced by sound health facts. The more the museum is open after the hours of the typical office and industrial day, the better is the chance to compete with the beer parlors for attendance of those whom you most want to reach.

It is difficult to anticipate the growth of a new venture, but Cleveland's experience makes it possible to lay down an axiom. A good program will inevitably lead to demands for an even better and larger one and a larger budget; for example, in Cleveland, television programs now require not only the time of the departments of education and public relations but also time and materials from the workshops for television "props." Adding an exhibit may have the same end result as occurred in the case of Juno, the Cleveland museum's talking transparent woman. Someone must supervise when she "speaks" for 15 minutes of each hour in her little science theater. Increased over-all attendance means a larger staff will be required to handle it.

In the beginning, the responsibility for financing mass health education rests squarely on the shoulders of the originators. Unless there is assurance of income by endowment, the first few years require careful planning toward a growing membership roster and contributions. The latter may come from business houses and from specialized voluntary health agencies or from almost any kind of lay group sufficiently interested in the project to take on money-raising activities among themselves for the health museum, with the community as beneficiary. An expanded program made possible by additional funds may be construed as something meaningful to the physician who feels an obligation to contribute some of his own effort to the health education of the community in which he lives. Omitting the countless extramural contacts made possible by Cleveland's expanding program in 1952, the visitors within the museum's walls were exposed to about 90,000 hours of voluntary health education, which included medical specialties. To do that much for the community, each of the area's 2,000 physicians would have had to devote 45 hours of his spare time, about one full work week, to health education.

HEALTH MUSEUM IN A HOSPITAL

The local hospital may offer the best place to start a health education exhibit and related activities that might be identified as a "health museum." "Museum" is a good term, in one sense, because the public knows that it means "things to look at," although too often the public relates it to the hush-hush, mustn't-touch atmosphere associated with many museums. The lively characteristics of the Cleveland Health Museum have been reported in this journal and others, and it seems safe to omit any description here of the Ohio exhibits and methods. A hospital is a natural place for health education. A person who usually thinks little about health becomes personally interested in the corporal house in which he lives when a supporting member sags, or the plumbing jams, or leaks develop, or even when he imagines such damages to his very personal property. In consequence, the modern hospital can be a place for education, a place of hope rather than a last resort, and a place where teaching "health through knowledge" can be extended to visitors.

The planners of the new Lankenau Hospital in Philadelphia planned a health museum for well or sick persons as an integral part of the 6 million dollar project to be completed in late 1953. Thus, Lankenau Hospital will become a center for community health education, with a program coordinated under an educational director working with schools, industry, and various agencies.

A valuable adjunct to the health museum section, for which many Cleveland exhibits are being duplicated, is an auditorium to be used for forums, lectures, demonstrations, and motion pictures. The medical society considering possibilities of health exhibits may well center upon the possible use of a room in a hospital as a start, even though few have $300,000 and 4,000 sq. ft. of specially designed exhibit space and facilities ready-made for a launching, as does Lankenau.[1]

PLANNING THE PROGRAM

The foregoing has not been offered as a blueprint applicable to a health museum anywhere. As stated early, its purpose is to indicate some of the problems faced in undertaking a new project and some of the answers as they have applied in Cleveland. It is with the same purpose that the leg of the tripod labeled "program" is discussed. Suppose that space is available and funds are in hand or in sight. What kind of a program should be offered? Here the Cleveland experience provides precedent that may be applicable. Dr. Gebhard says that principles are the same here as in Europe or in "darkest Africa" for that matter. "One of the earliest considerations should be the scope of the program. Here personal preferences, likes and dislikes are very likely to crop up. Some may lean to the biological—from conception to senility. Others may want to present the effects of geographical location on health. Population or racial themes may be a favorite of someone else, or nutrition, medical specialties or whatever. All these and many others are perfectly legitimate subjects for health exhibits but the secret of success is not in completeness of a few but the variety of selection so that the over-all exhibits will have something for every age and interest, what We the People want to know." The scope of the program in Cleveland was originally "the presentation of scientific truth about the human body. . . ." That has been broadened to include what affects the body, thus opening the way for exhibits, newspaper articles, and radio and television programs on anything from allergies and air pollution, as represented by the annual pollen count, to zymosis, as exemplified by life-like models of babies as they appear with cases of scarlet fever and diphtheria. In addition to year-round exhibits on basic biology, food facts, and other timeless subjects, Dr. Gebhard has tuned the museum to the seasons. Hot weather hazards, from food spoilage to poison ivy, the common cold, poliomyelitis, and measles, are examples of seasonal or cyclic subjects.

First steps are not very different from those in the initial organizing of a new hospital. There is, however, a main difference beyond that point. According to Dr. Gebhard, "Patients must go to a hospital when conditions call for hospitalization, but the public exercises its free will in visiting a health museum." What the vanguard sees there will determine to a considerable degree the subsequent attendance of friends and acquaintances. "Only a tiny portion of any urban population is interested in flat charts of disease, vital statistics, blown-up dietary lists or cadaverous specimens." A model that only roughly simulates the heart and that flashes or thuds with each beat can inevitably draw attention to closely-related health educational facts about how many times a minute, hour, day, or lifetime the heart beats and why and how such a remarkable engine should be cared for. This does not mean that nothing realistic should be included among the exhibits. One of the most effective exhibits at the Cleveland museum is the life-like model of an appendectomy. Often, visitors comment on its simplicity, usually in terms that indicate fears allayed as they apply to the speaker and to those nearest and dearest. That is effective patient education. I doubt that better patients would result from the same technique as applied to cancer, gallstones, or an amputation. Realism must be tempered with judgment. "Basically a health museum should be a Health museum, not a museum of diseases," in the Gebhard summation.

PROGRAM PLANNERS

Although outstanding exceptions can be cited, physicians as a class are not notable as health educators. In industry, it is axiomatic that some outstanding salesmen have been dismal flops as executives. The good salesman and the good physician are often solo artists, doing their best work person-to-person. Both may have difficulty in projecting, even to an understudy, whom they want to teach, the thinking, methods, and techniques that have made them great in their own specialized fields. Therefore, in planning methods for public health education, the typical physician will do well to draw on the experience of others whose medical knowledge may be limited but who are teachers rather than practitioners. Teaching large segments of the public requires a bit of the theatrical approach, the primarily medical aspects being directed by a board or committee in case the teacher is not a physician.

In seeking personnel, it should be remembered that the profession of health education has grown to the point at which graduates in the field are making their mark on the times. The curator of exhibits in some other type of science museum may well be considered for the position of active head of a local health museum. A member of the staff of a teachers' college may fit well in the job. With additional training, a public relations director of a state or other medical society may fill the need. These suggestions are enough to indicate directions for a search that should turn up the right person. A physician with a flair for utilizing the community as his classroom is the ideal head for a health museum. Given the choice, however, between (*a*) a public spirited physician with no experience in heading community activities and (*b*) a health educator or comparable person with administrative experience in group work, there should be a little hesitancy in hiring Mr. B., with the hope that Dr. A will go along with the decision and will contribute his invaluable knowledge and spirit to the project. In the early stages, the acting head could be associated on a part-time basis.

NEED FOR INDEPENDENCE

To serve its community best a health museum should be a unit on its own rather than an extension service of an organized medical society. There are several reasons for this, not the least of which is that organized medicine must not be wrong, while a health education entity can experiment. Also, museums have their own methods and rules, many of which are based on a centuries-old experience, for example, museum persons recognize "museum fatigue" and arrange exhibits and tours accordingly. The operation of a health museum is comparable in most ways to the operation of a business. Although it does not operate for profit, the museum must have various departments, as does a business, and it operates under a management that is responsible to a board of trustees. Every department is an essential part in the institution's relations with outsiders. Organized publicity is only a part of "Good Conduct—and Getting Credit for It,"[2] the true meaning of good public relations. The kindly, informed physician who knows from experience how best to tell the facts to the uninformed or misinformed patient can be naive in matters concerned with reaching the wider public consciousness. I can recall only one major difference in opinion with some of the physicians with whom it has been my privilege to associate for about 13 years. It should be told to illustrate the difference in viewpoints.

---

[1] Gebhard, B.; Gay, D., and Kling, V.: Lankenau Pioneers America's First Hospital Health Museum, Mod. Hosp. 80: 74-75 (April) 1953.

Some of the physician-members felt that the museum should take a public stand on "socialized" medicine when the issue was incandescent. Such a pronouncement could have weakened the museum's influence immeasurably while setting a precedent that could have led into bogs of argument and misunderstanding. A health museum can take sides in problems of poliomyelitis, diabetes, dietary deficiency, and air pollution, as examples of man's enemies recognized world-wide. It cannot be a protagonist for opinions and at the same time keep an independent status as a specialized center for the dissemination of unbiased facts gathered from medical and health science, which know no boundaries. A health museum is set on a hill in a glass house, where every segment of the public has access. When the museum has found itself, it goes beyond the intramural exhibits into extramural activities throughout the community. The public forms its own opinions as to the motives, purposes, methods, authenticity, and worth of such a public institution. Regardless of how pure its motives and altruistic its objectives, some persons will misunderstand. It takes time to lay the true picture before a community. In the Cleveland museum's early days a principal objective was to convince key persons that America's first health museum was not set up by a few physicians for personal profit or special propaganda. During the first year, one skeptical newspaper man spoke of it as "Dr. ————'s health racket." Later, he wrote a favorable editorial. Another example is the effect of the museum's acquisition of the three-dimensional models of human reproduction from Dr. Robert L. Dickinson and sculptor Abram Belskie. A whispering wave of "birth control" followed, not maliciously but simply as a live topic for conversation. This was, however, nothing new. In 1940, while remodeling was under way, Dr. Gebhard, newly from New York, designated one room as the "Maternal Health" room. To many Clevelanders those words are synonymous with a "planned parenthood" organization. The room became the "Mother and Child" exhibit.

GROWTH IN SCOPE OF ACTIVITIES

Any long-time member of the Cleveland museum's board will agree that no group should start a health museum unless it expects it to grow. The original concept was that of a building housing exhibits that the people would visit. It is still the most important item, budgetwise, and perennially offers the most constant contact with the people. Yet, the housewarming was hardly over, in 1940, when telephone calls and personal visits showed widespread and active interest in getting information that such an institution, from its name, might be expected to have on hand. Soon it was drawn into special interest health activities. In a few cases, it was evident that some organizations feared that merging their effort with the museum might take some of the credit away from themselves. Had the health museum at that stage insisted upon "top billing," much cooperation would have been lost, with the community as the main loser. It has now become apparent that the staff's intent is to aid every legitimate project with all the information, experience, and ideas it has available. Today, the museum often furnishes the ideas, plans the methods, and plays a principal part in execution of a project for which some inexperienced organization comes for help. If this type of help is given often enough, eventually a health museum will attain the position of "big brother," regardless of whether brother appears when credits are handed out. When local newspapers or the radio or television industry has learned to turn to the museum as a source of information, for checking facts, or for comment, the health education project will have arrived. A newspaper conducting a pre-Christmas-holiday drive on drunken driving came to the Cleveland Health Museum for much of its material, which, incidentally, consisted in part of the American Medical Association's exhibit on the subject.

Even though the existence of a health museum is good, the museum cannot afford to be static. A busy attitude is a requisite. This, may draw some criticism from conservative groups and individual persons, until they learn that a museum's objectives can be reached only by activity. This necessitates being conspicuous occasionally for the good of community health education. In Cleveland, an early self-promoted activity was a radio program with members of the Academy of Medicine of Cleveland as speakers. In early 1953, the museum and the academy embarked cooperatively on a television health education project. The early spade work in locating a sponsor and arranging practical details (they are multitudinous in this field) eventually brought the academy into the project as a natural collaborator, because it has the medical authority and personnel needed to give the desired educational impact. The series, which is televised in Cleveland and "piped" to an Ohio-wide network, consists of one-subject programs presented as interviews with physicians. The camera, shifting to the home of a "typical" Ohio family, catches the members conversing on that day's subject. Their ideas on health furnish the opportunity for the physician to present truths while correcting misinformation. Printed digests of each program are offered. Response has come more quickly and in greater numbers than anyone had anticipated, proving again the public's interest in health matters. The sponsor is an oil company. Although some may shudder at the thought of commercial sponsorship of any public health activity, others will admire a sponsor with the courage and convictions to invest in a program for public benefit with a minimum of "commercials." Commercial sponsorship makes it possible for the museum, like the family physician, to make house calls.

---

[2] Martin, D.: Getting Credit, Ohio's Health 111: 1-7 (Dec.) 1951; Public Relations Is Nice Work if You Can Take It, The Quill (Sigma Delta Chi), June, 1951, pp. 10-20.

CONCLUSIONS

"The public is not interested in public health," according to Dr. Gebhard. "It is concerned most with personal health. Therefore the basic appeal should be to individuals as members of a family." Enough has been stated here to indicate how the pioneer health museum carries activities beyond the museum walls into outside meetings, into publications, and into homes. Information that is uninvited frequently evokes high appreciation, as proved by the museum's mail response. A health museum project may be started advantageously elsewhere in a small way as far as space and funds are concerned. A large program can stem from a small space area, accomplishing one thing, if nothing more: it can bridge the gaps between sporadic health "drives" and thus can be the one constant force in education of patients before they get sick.

COUNCIL ON PHARMACY AND CHEMISTRY

REPORT TO THE COUNCIL

The Council has authorized publication of the following report.

R. T. Stormont, M.D., *Secretary.*

PREPARATION AND MAINTENANCE OF STERILE OPHTHALMIC SOLUTIONS

Frederick H. Theodore, M.D.
and
Robert R. Feinstein, New York

Serious ocular infections resulting from the use of contaminated ophthalmic solutions are becoming increasingly prevalent. This situation may be directly attributed to the astounding fact that in the United States, until recently,[1] no section of the Federal Food, Drug, and Cosmetic Act was interpreted as requiring manufacturers and dispensers of eye medicaments to prepare sterile solutions fortified with adequate preservatives.[2] Recognition of this health and economic hazard is growing. At present the Federal Food and Drug Administration, the United States Pharmacopeia, the National Formulary, and the American Medical Association are all working toward a common goal: proper safeguards for ophthalmic drugs. The A. M. A. Council on Pharmacy and Chemistry has required sterility of commercially prepared ophthalmic solutions as a prerequisite for Council approval for some time. Objections have been raised in regard to the feasibility of certain aspects of legislation concerning this problem; these objections served to delay the formulation of satisfactory statements of policy. This report is submitted for the purpose of clarifying and simplifying the problem, which, when considered in detail, is by no means insurmountable.

The basic source of ophthalmic solutions used by patients is either a commercial manufacturer or a retail or hospital pharmacy compounding its own solutions. The particular danger of large-scale commercial preparation of solutions is that, if contaminated, the long interval between manufacture and use by the patient allows the widespread distribution of many units of grossly infected medicaments. Retail or hospital pharmacies accustomed to preparing stock bottles of frequently prescribed ophthalmic solutions are an equally serious, and possibly more frequent, source of infection, should lack of sterile procedures and careless handling result in contamination of such large containers. It is the opinion of the authors, however, that at the present time regulations should be formulated controlling the manufacture of only commercially prepared solutions. This should not be difficult. Regulation of the retail and hospital pharmacy presents more legal and other jurisdictional complications. It is felt, therefore, that for the time being an educational program is the best approach as regards noncommercial compounding. This already has been begun in cooperation with the National Society for the Prevention of Blindness.[3] Ultimately, the regulation of pharmacies must also be achieved, if all loopholes are to be closed. This report deals specifically with the control of the manufacture of eye solutions by pharmaceutical concerns. In the light of recent events, these companies are desirous of cooperating toward this end, because they realize that the minor additional expense and difficulty involved are well worth while. The related problem of ophthalmic ointments[4] is not discussed in this report.

SPECIAL ASPECTS OF OCULAR MICROBIOLOGY

Although the eye is subject to infection by many types of micro-organisms, experience indicates that only a relatively small variety of bacteria, fungi, and viruses must be considered in any discussion of ocular infections caused by contaminated eye solutions. In this regard the most important bacterium of all is Pseudomonas aeruginosa (Bacillus pyocyaneus). All recent episodes of drug infection have resulted from this organism, which may cause the most serious type of corneal ulcer encountered in ophthalmology. Moreover, most corneal infections caused by Pseudomonas species appear to be traceable to contaminated ophthalmic solutions and ointments. This gram-negative bacillus grows readily in most mediums and forms both toxins and antibacterial products. To the latter may be ascribed the fact that the bacterium grows in pure culture as other contaminants are killed off. Tap water and solutions of the following ophthalmic drugs have been found to be contaminated with Ps. aeruginosa: fluorescein, physostigmine (Eserine), pilocarpine, scopolamine, atropine, ethylmorphine hydrochloride, cocaine, dibucaine (Nupercaine) hydrochloride, tetracaine (Pontocaine) hydrochloride, cortisone acetate, the sulfonamides, homatropine hydrochloride, methylcellulose, and sodium chloride. In other branches of medicine the importance of Pseudomonas organisms as pathogens is also becoming more appreciated. Investigators in the field of antisepsis now suggest that this bacterium should be employed as a test organism along with those generally used for evaluation of antibacterial activity.

Another group of gram-negative bacilli that are capable of serious corneal infection are members of the genus Proteus. They have been found as contaminants in methylcellulose solutions. The only other gram-negative ocular pathogens of clinical importance are Hemophilus influenzae, Hemophilus conjunctivitidis (B. Koch-Weeks), Neisseria gonorrhoeae, N. meningitidis, Escherichia coli, Klebsiella pneumoniae, and Moraxella lacunata. These rarely, if ever, appear to cause serious drug contamination.

[4] Lehrfeld, L., and Donnelly, E. G.: Contaminated Ophthalmic Ointments, Arch. Ophth. **40**: 39 (July) 1948.

The only common gram-positive ocular pathogens relevant to this report, that is, organisms that have been found to cause drug contamination, are Micrococcus pyogenes var. aureus, species of Streptococcus, and Diplococcus pneumoniae. On theoretical grounds, however, Bacillus subtilis, an ever-present spore-forming air contaminant of low virulence, must be mentioned. When this organism infects the vitreous humor a serious abscess occurs. Therefore, care must be taken to prevent air contamination of drugs used in ocular surgery or in the treatment of penetrating injuries of the eye. From a practical aspect the only pathogen of the fungi to be considered is Aspergillus fumigatus. Molds in eye solutions generally are harmful only because they accelerate deterioration of the active drugs; they do not cause ocular infections.

Contamination of ophthalmic solutions by viruses of ocular significance has not been known to occur during manufacture. Although it is theoretically possible, no instances of contamination by manufacturing personnel suffering from ocular infection of viral origin have been reported. However, solutions of tetracaine hydrochloride and sodium sulfacetamide have been contaminated in physicians' offices by the virus of epidemic keratoconjunctivitis after the droppers have been accidentally in contact with the patients' secretions during active infection. In one instance,[5] as many as 42 cases of this disease were caused by one infected bottle of tetracaine hydrochloride. The virus of trachoma similarly may infect clinic bottles of eye solutions that are used in treating more than one patient. The viruses of herpes simplex, vaccinia, and molluscum contagiosum may conceivably cause drug contamination, but instances have not been reported. The only certain prophylaxis in office and clinic treatment of virus infections of the external eye appears to be the use of single dose disposable units of ophthalmic solutions, because the preservatives now available are ineffectual against viruses. In fact, in the office treatment of serious ocular infections caused by any type of pathogenic organism, single dose units are preferable.

SUGGESTED PROCEDURE FOR THE COMMERCIAL MANUFACTURE OF OPHTHALMIC SOLUTIONS

The technique to be described has proved successful in large pharmaceutical operations for the preparation of sterile solutions of heat labile drugs. In essence, it is simply one of filtration of previously prepared solutions containing suitable preservatives (figure). The actual steps of the procedure are standard pharmaceutical practice and need not be described here. Unless attention is paid to the following details, however, the procedure will not result in uniformly sterile and potent ophthalmic solutions and may give a false sense of security:

1. The containers and equipment should be autoclaved either in open inverted position or with sufficient internal moisture to ensure full exposure to saturated steam without air mixture at 121 C for at least 20 minutes. Although dropper assemblies are available with plastic caps that can be autoclaved, they are not in general use as yet. The plastic caps commonly used cannot tolerate the temperatures in an autoclave, and, therefore, they should be soaked in a 1% solution of phenol at 37 C for 30 minutes, but all container parts that cannot be autoclaved should be replaced as soon as possible by those that can.

2. The choice of the proper filter is of the greatest importance. Sintered porcelain filters should be used. Those manufactured by Selas Corporation of America are preferred for the following reasons: 1. They are available in a large variety of candles, funnels, and disks. 2. The no. 03 porosity (pore size 0.6 μ) will remove all bacteria, fungi, and some of the larger viruses. 3. They do not carry electric charges, and therefore will not remove active ingredients from solutions. 4. They are chemically inert and will not alter the pH of the solution being filtered. 5. They are relatively resistant to thermal shock and can be repeatedly sterilized by autoclaving and easily cleaned with chemicals or by heating to cherry-red heat in a muffle furnace. 6. They can withstand high pressures and vacuums.

3. Suitable vacuum or pressure pumps should be used. Nitrogen (purified grade) is the gas preferred for use in pressure systems.

4. The role of the personnel employed during the various stages of the entire operation deserves specific emphasis. While ordinary cleanliness and hygienic precautions will suffice during the earlier steps in the manufacture of ophthalmic solutions, it must be definitely understood that no employee engaged in any part of the operation should be suffering from infections of the eyes, the upper respiratory tract, or the skin, including common conditions such as herpes simplex. The filtration procedure will not remove most viruses, and it is not wise to place absolute trust in the sterilizing powers of ultraviolet ray radiation. Moreover, employees suffering from a genitourinary or gastrointestinal infection should not be allowed in the area set aside for the manufacture of ophthalmic solutions because these infections may be caused by Pseudomonas organisms. Employees engaged in the actual filling of the individual units must prepare themselves in the same manner as a surgeon prior to entering an operating room. A surgical scrub-up, the use of a sterile mask covering both nose and mouth, and sterile cap, gown, and gloves are mandatory.

5. The entire working area should be bathed in ultraviolet light. However, exposure of personnel to irradiation for the entire work period might result in serious eye injuries unless proper precautions are taken to shield the eyes. Many pharmaceutical houses irradiate only during those times when workers are away from the area, such as during lunch or rest periods. It is important that germicidal lamps be checked at regular intervals to insure adequate emission of the germicidal wave lengths of ultraviolet light. The mere fact that these lamps may glow brightly does not insure adequate protection or a sterile atmosphere. Periodic cultures of air and surfaces should be taken in these rooms. Effectiveness of irradiation will be reduced in an area not kept scrupulously clean; proper attention to cleanliness will do more toward maintaining a low bacterial count than reliance on irradiation.

PRESERVATIVES FOR OPHTHALMIC SOLUTIONS

The choice of the proper preservative is of the greatest importance. It must be realized, however, that no antiseptic available at present as a preservative for ophthalmic solutions can be relied on. Preservatives that are generally considered reliable may be found inadequate on occasions, such as in the event of particularly gross contamination of the antiseptic or

---

5. Thygeson, P.: Epidemiology of Epidemic Keratoconjunctivitis, Am. J. Ophth. 32:951 (July) 1949.

when inactivation of the antiseptic occurs. Thus the addition of preservatives to solutions not prepared under sterile precautions, as has been suggested by some investigators, can never serve as a substitute for sterile preparation of these drugs.

In addition to satisfactory bacteriostatic and fungistatic action, a suitable ophthalmic preservative must have the following qualifications: 1. It should be nontoxic. 2. It should be nonirritating to ocular tissue. 3. It should remain active indefinitely. 4. It should not have any allergenic or sensitizing tendencies. 5. It should be compatible with most of the drugs and excipients used in ophthalmology.

Six types of antiseptics have been suggested by various investigators for use as preservatives in ophthalmic solutions.[6] Preferences in the choice of preservatives seem to change, often without basis in fact. A few years ago the mercurials were preferred; now the cationic wetting agents and the esters of *p*-hydroxybenzoic acid are favored; however, chlorobutanol, one of the oldest preservatives, still appears to fulfill best the aforementioned requirements. The reasons for this are as follows:

1. The esters of *p*-hydroxybenzoic acid are more useful as fungicides than as bacteriostats. Moreover, because of their poor solubility in water, potassium hydroxide must be added in order to reach a concentration high enough to be effective against Pseudomonas and many other ocular pathogens.[7] The addition of even a small quantity of such a strong alkali would increase the ocular irritation that is likely to occur with this group of chemicals. Moreover, increasing the pH will accelerate the deterioration of the active drugs used.

2. The mercurials are usually effective against the pseudomonas and other ocular pathogens. They have several serious disadvantages, however. First, they often cause allergies with prolonged use. Second, only the more toxic inorganic mercurials can be used in ophthalmic solutions requiring acid mediums; the organic mercurials are soluble and stable only in alkaline solutions.

3. Phenols and chlorinated derivatives are too irritating in their effective concentrations to be useful in ophthalmic solutions.

4. Formaldehyde sodium sulfoxylate, recommended by various investigators, is also too irritating to be used as a preservative for ophthalmic solutions.

5. The cationic wetting agents (benzalkonium, cetyl benzalkonium, and phemerol) appear to be of questionable value for use as preservatives. Their bacteriostatic effect is too variable and, at times, unreliable, especially against Ps. aeruginosa.[8] It has been shown that the antibacterial action of active quaternary compounds may be diminished by the presence of less active quaternary ammonium salts because of an interference phenomenon occurring on the surface of the bacterial cell or within the cell itself.[9] This could serve as an explanation for the sometimes capricious behavior of the quaternaries, and especially for those instances when certain strains of Pseudomonas were found to grow profusely in solutions containing cationic preservatives. In addition, cationic wetting agents are easily inactivated by high molecular anionic chemicals, such as soaps and other detergents, as well as compounded and natural rubber. They are incompatible with and therefore inactivated by certain ophthalmic drugs such as pilocarpine nitrate, all salicylates, fluorescein, and boric acid. Furthermore, both their bacteriostatic and fungistatic actions may be influenced adversely by changes in pH.

Chlorobutanol appears to fulfill all the aforementioned requirements for a satisfactory ophthalmic preservative. The mechanism of the effectiveness of a 0.5% solution as a preservative is not well understood. In fact, surprisingly little has been written about this very useful and widely employed drug. Its complete antibacterial and antifungal spectrum has not been evaluated. On the basis of experimental observation and experiences during the past 50 years of its use as a preservative,[10] however, its effectiveness against the usual pathogens appears to be well established.

Our own experiences have proved extremely satisfactory. In order to ascertain how long chlorobutanol is effective, a number of office bottles of sterile ophthalmic solutions, opened and used frequently over periods up to three years, were cultured by us on blood agar, thioglycollate medium, and glucose broth. All of the solutions proved to have remained sterile except one bottle of commercially prepared methylcellulose in use for over two years, which proved to be contaminated with Proteus vulgaris. Since these dropper bottles had been handled by office assistants, it is reasonable to assume that sometimes the dropper touched the eyelids or eyelashes of patients, yet the solutions remained sterile. Experiments by one of us (F. H. T.) have confirmed those of McCulloch,[11] who found that a 0.3% concentration of chlorobutanol was necessary to prevent growth in solutions inoculated with a loop-full of a fresh culture of Pseudomonas. Our investigations indicate that even weaker concentrations (0.125%) are effective against certain strains of Pseudomonas and P. vulgaris. The inoculant, of course, represented a number of organisms far greater than that liable to occur through contamination during use by patients.

There are two minor disadvantages in the use of chlorobutanol as a preservative. First, in the preparation of solutions, care must be taken to maintain a temperature high enough to dissolve the drug but not high enough to destroy it. Second, it decomposes slowly in alkaline solutions. Since most ophthalmic solutions are buffered to a pH of 7.4 or below, this is not a serious drawback.

HANDLING OF THE FINISHED PRODUCT

Sterile, commercially prepared ophthalmic solutions should be dispensed only in their original bottles. For this reason they should be available in small units never larger than 15 cc. and preferably smaller. The eye dropper should be sterile and packaged to maintain sterility. Packaging and sealing as part of the unit ready for use will obviate contamination resulting from careless handling by the pharmacist. Manufacturers should clearly label the container with adequate instructions to the pharmacist concerning proper handling.

CONCLUSIONS

1. Governmental regulations now exist insuring the sterility of commercially prepared ophthalmic solutions. These requirements should ultimately include the retail and hospital pharmacies, but at present an educational program is desirable.

2. A practical method for obtaining solutions free from bacteria and fungi that is applicable for heat labile ophthalmic drugs is described.

3. The use of chlorobutanol as a preservative agent is suggested.

4. Care in the handling of the finished product is an important part of the success of the program.

[6] Another chemical that may prove to be useful as a preservative is phenylethyl alcohol. Dr. John H. Brewer, Baltimore, has found it to be effective as a bacteriostatic agent in ophthalmic solutions against gram-positive and gram-negative organisms, particularly Pseudomonas aeruginosa (personal communication to the authors).

NARCOTIC SUPPLIES

From time to time there have been published in THE JOURNAL statements on the responsibilities of physicians under the Harrison Narcotic Act. In addition to having a registry number that must be renewed each year, the practicing physician must exercise control over his supply of narcotics if for no other reason than to protect himself. In the same light, pharmacists and drug wholesalers must observe certain responsibilities if they are to avoid difficulties with the Federal Bureau of Narcotics.

Physicians cannot obtain nonexempt narcotics directly from pharmacists (unless they are registered as narcotics wholesalers) for use in their offices; they must obtain official order forms to secure narcotics for their practice. They can, of course, prescribe narcotics for patients and expect such prescriptions to be filled at pharmacies and in hospitals. However, an interesting aspect of the prescribing of narcotics concerns the liability of the pharmacist, who is responsible under the federal law for determining if the prescription was written by a physician (or other authorized practitioner) and who thus must always be on the alert for forged signatures and for prescriptions that have been stolen. When in doubt the pharmacist should consult with the physician whose signature appears on the prescription and when he takes such action he is not being arbitrary but rightfully cautious.

A narcotic order received by telephone cannot be delivered until the pharmacist or his manager receives a written prescription. The prescription cannot be mailed or delivered later. Furthermore, a narcotic prescription cannot be refilled; nor can it be signed by anyone other than the physician, who must sign, not type or stamp his name. He cannot even ask his nurse to sign for him. Nor can he sign several blank orders and leave them with a pharmacist to be used later as the need arises. Each prescription must contain the date on which it is written, the full name and address of the patient, and the name address, and registry number of the prescribing physician.

Physicians are likely candidates for addicts to approach in the hope of obtaining narcotics or an order for them by one trick or another. The excuses offered in the average doctor's office are almost too numerous to mention, but nevertheless the physician must always exercise his best judgment to detect such falsified tales if he wishes to avoid innocently coming into conflict with the law. In addition, his car if recognized as belonging to a physician may be broken into by addicts looking for narcotics; or his office may be ransacked. Or he may even be held at gun point by the more desperate. Regardless of the method of attack by an addict the doctor must account for his narcotic supplies, and it may even be wise for him to keep his narcotics divided for hiding in several places. At all times they should be kept under lock and key.

There are comparatively few honest persons who would deliberately invite trouble by carelessly handling narcotics. There are others, however, who risk embarrassment and misunderstanding because of thoughtlessness or even ignorance of good practices. The safeguarding of narcotics is a responsibility of several interested groups—doctors, pharmacists, drug wholesalers, drug manufacturers, and law enforcement officials. Each usually tries to use common sense and to respect the laws. On occasion there may be an unintentional slip, and when such occurs a tolerant attitude can be taken only when there is evidence of unquestionable good faith on the part of the offender. Thus it behooves everyone to appreciate not only his own responsibilities but the problems of others who are involved in the handling, use, and control of narcotics. It is too serious a problem to permit impatience and intolerance.

TOXOPLASMOSIS

Nicolle and Manceaux described in 1908 an intracellular parasite observed in smears of the spleen and other organs of the North African rodent, the gondi. Splendore in the same year made the same discovery in Brazil. These investigators named the parasite Toxoplasma gondii and regarded it as a protozoon. According to Sabin,[1] the cardinal characteristics of the species are (1) typical morphology and staining characteristics of extracellular and intracellular forms in films, fresh tissue, or exudate; (2) pathogenicity for such animals as mice, guinea pigs, rabbits, and chicks; (3) obligate intracellular parasitism; and (4) immunologic relationships with established strains. Proof that Toxoplasma is the cause of certain disease conditions in human beings was first obtained in 1939.

The discovery by Sabin and Feldman [2] in 1948 of a new immunologic phenomenon, the so-called cytoplasm-modifying or dye test, became the basis of a widely used quantitative test for the determination of antitoxoplasmotic antibody. The cytoplasm of Toxoplasma contained in fresh exudate has a great affinity for certain dyes; methylene blue at pH 11 stains it a deep blue. Combination of toxoplasma with antibody does not in itself affect the affinity of the cytoplasm for the dye, but, when such antibody-treated Toxoplasma are acted on by a complement-like accessory factor, the affinity for the dye is lost and the cytoplasm remains unstained. Human beings, animals, and birds develop this cytoplasm-modifying antibody after injection of Toxoplasma.

The most commonly recognized clinical manifestations of human toxoplasmosis are the result of congenital infection. The diagnosis is readily established by serologic methods, especially during the first five years of life. The clinical manifestations of congenital toxoplasmosis are chorioretinopathy, cerebral calcification, hydrocephalus or microcephalus, and psychomotor disturbances. The occurrence of these clinical manifestations, Sabin warns, does not in itself indicate that the cause is toxoplasmosis; however, he states that the incidence of serologic confirmation of toxoplasmosis in the presence of this syndrome can be as high as 80 or 90%. Chorioretinopathy is the most important and suggestive sign of congenital cerebral damage.

---

[1] Sabin, A. B.: Toxoplasmosis: Current Status and Unsolved Problems: Introductory Remarks, Am. J. Trop. Med. 2: 360-364 (May) 1953.

[2] Sabin, A. B., and Feldman, H. A.: Dyes as Microchemical Indicators of a New Immunity Phenomenon Affecting a Protozoon Parasite (Toxoplasma), Science 108: 660-663 (Dec. 10) 1948.

The chief practical benefit to be derived from a specific diagnosis of congenital toxoplasmosis is the good prognosis for subsequent children. In Sabin's experience, 50 mothers who had given birth to one child with congenital toxoplasmosis subsequently gave birth to one or more normal children without the disease. The consensus is that only mothers with primary acute infection, which may be entirely inapparent or unrecognizable, can transmit toxoplasma to their offspring in utero. Millions of women possessing plasma antibodies have given birth to children without toxoplasmosis. Those who gave birth to affected children invariably showed the high antibody titers expected of recent infection.

According to Frenkel,[3] the range of animals that can be infected with toxoplasma is unique for the protozoa. All mammals and birds investigated have been found susceptible to toxoplasmosis. It is probably the most ubiquitous and prevalent of parasites. Neonatal toxoplasmosis is probably always the result of a congenital transmission of the infection, according to Jacobs. Toxoplasma is an intracellular protozoon of which proliferative and cyst forms are recognized. During the acute infection, proliferative forms are characteristically seen. Cysts are characteristic of chronic infection. The Sabin dye test is a reliable sensitive indicator of antibodies for Toxoplasma. The other serologic procedure is the complement fixation test described by Warren and Russ in 1948 and by Sabin in 1949.

Two types of disease produced are in humans by Toxoplasma: acquired and congenital. Acquired toxoplasmosis manifests itself by fever, papular rash and encephalitis, myalgia, arthralgia, myocarditis, lymphadenopathy, and pneumonitis. Congenital toxoplasmosis results, according to Feldman,[4] during the parasitism of an inapparent infection that has occurred in a pregnant woman. Such an event, depending on the stage of pregnancy during which the infection was contracted, may have any of the following results: the fetus may die in utero after abortion; the fetus may be born either prematurely or at term with active toxoplasmosis; or the fetus may be normal at birth and appear quite well for days, weeks, or months before certain structural changes or symptoms are noted. Active disease in the newborn may be manifested by fever, jaundice, rash, hematomegaly, splenomegaly, xanthochromic spinal fluid, and convulsions. Various disabilities may make their appearance among infants and children who appeared quite normal at birth, such as hydrocephaly or microcephaly, chorioretinitis, psychomotor retardation, or convulsive episodes. Feldman[4] studied 103 patients with toxoplasmosis. Of these, 99% were found to have chorioretinitis, 63% to have cerebral calcification, 56% psychomotor retardation, 50% hydrocephaly or microcephaly, and 50% convulsive episodes. Sabin and Warren[5] found that the sulfonamides showed definite activity against toxoplasmosis in mice and rabbits. Sulfonamides, particularly sulfadiazine and related compounds, are definitely active against Toxoplasma in experimental animals. Since they are safe drugs and are readily available, Eyles[6] feels that they should be used in cases of human toxoplasmosis. The most promising recent development in the chemotherapy of toxoplasmosis was the discovery that the pyrimidine drug Daraprim (2:4-diamino-5-[*p*-chlorophenyl]-6-ethyl pyrimidine) and related compounds have definite therapeutic effect against Toxoplasma. Perhaps more important is the fact that these drugs act synergistically with the sulfonamides. The antibiotics have only a slight effect even at extremely high dosages. None of the other compounds so far investigated has been outstandingly effective.

The relative incidence of inapparent and clinically recognizable forms of toxoplasmosis remains to be elucidated. Recent studies suggest, as stressed by Sabin, that the parasite Toxoplasma will be shown to represent an almost perfect host-parasite relationship in which the parasite only rarely causes serious damage to its hosts and the hosts are not too intent on destroying the parasite, an instance of a lot of infection and little disease.

THE 1952 MEDICAL CARE DOLLAR

The Bureau of Medical Economic Research has recently published another item in its series on personal consumer expenditures for medical care based on data recently issued by the United States Department of Commerce.[1] Total personal consumer expenditures for all goods and services rose from 208 billion dollars in 1951 to 218 billion in 1952. The medical care portion increased from 9.0 billion dollars to 9.6 billion dollars, from 4.3% to 4.4% of the total; an unknown portion of this increase was due to the large number of births. The physician's share of the personal consumer dollar spent for medical care decreased from 28.1 cents to 27.8, while the hospital's share rose from 24.0 cents to 24.8. Thus the data for 1952 indicate a continuation of the long trend downward for the physician's share and upward for the hospital's share. The dentist's share also declined slightly.

On the basis of these data and other data published by the United States Department of Labor, this study reports that in 1952, as in 1951, 54% of an average week's wages of production workers in manufacturing industries was required to purchase the same amount of medical care and drugs that would have required an entire week's wages in the base period 1935-1939. The corresponding percentage for physicians' services was 50 in both years.

ORGANIZATION SECTION

MEDICAL PUBLIC RELATIONS INSTITUTE

Drake Hotel, Chicago
September 2 and 3, 1953

PROGRAM

Wednesday, September 2

OPENING OF REGISTRATION

8:30 a. m., Ballroom Foyer

SCREENING OF TELEVISION FILMS

9 a. m., Ballroom

These are new filmed TV shows available for exclusive use of state and county medical societies.

What to Do

Six five-minute films on home medical emergencies

A Citizen Participates

Half-hour documentary telling how a town organized to find itself a physician

Operation Herbert

Major, A. M. A.-produced, TV play, starring comedian Jackie Kelk, explaining cost of medical care

YOUR 1953 INSTITUTE

10:15 a. m., Ballroom

The Job to Be Done

Leo E. Brown, Chicago, Director, Department of Public Relations, American Medical Association

A. M. A. Sends Greetings

Ernest B. Howard, M.D., Chicago, Assistant Secretary, American Medical Association

THE PLACE OF TELEVISION IN YOUR PR PROGRAM

10:30 a. m., Ballroom

Chairman: John F. Conlin, M.D., Boston, Director, Medical Information and Education, Massachusetts Medical Society

The Public Service TV Show

Robert K. Richards, Washington, D. C., Administrative VP, National Association of Radio and Television Broadcasters

How the A. M. A. Can Help

W. W. Bauer, M.D., Chicago, Director, Bureau of Health Education, American Medical Association

Cooperating with Medical Schools and Health Departments

James Rogers Fox, M.D., Minneapolis, University of Minnesota

Local Promotion of Network Medical Shows

G. Frederick Roll, Philadelphia, Manager, Public Relations, Smith, Kline & French Laboratories

Questions from the Audience

LUNCHEON

12:30 p. m., French Room

Get Acquainted Session. No speaker

FIRST GROUP OF "HOW-TO-DO-IT" CLINICS

2 p. m.

Institute registrants can attend any of three clinic meetings

Clinic One, Parlor F

Topic: Tips on conducting a successful PR program on a small budget. In a county society. In a state society.

Discussion Leaders:

D. J. Parsons, M.D., Springfield, Ohio, Chairman, Public Relations Committee, Clark County Medical Society

John C. Foster, Sioux Falls, Executive Secretary, South Dakota State Medical Association

Clinic Two, Parlor D

Topic: What techniques can be used to develop interest and support in labor of medicine's PR program?

Discussion Leaders:

B. M. Overholt, M.D., Knoxville, Chairman, Health and Medical Care Council, Tennessee Medical Foundation

Harry A. Lehman, Fort Wayne, Ind., Executive Secretary, Fort Wayne Medical Society

Clinic Three, Parlor C

Topic: What television writing and production techniques are best adapted to medical shows?

Discussion Leaders:

Ad Schneider, New York, Executive Producer, National Broadcasting Company

Robert K. Richards, Washington, D. C., Administrative VP, National Association of Radio and Television Broadcasters

John C. Kadonsky, Milwaukee, Director, Public Information, Medical Society of Milwaukee County

SECOND GROUP OF "HOW-TO-DO-IT" CLINICS

3:30 p. m.

Institute registrants can attend any of three clinic meetings

Clinic Four, Parlor C

Topic: What methods can be used to combat cultists and quacks? On a state level? On a county level?

Discussion Leaders:

James A. Waggener, Indianapolis, Executive Secretary, Indiana State Medical Association

Frederick W. Miebach, New York, Director, Public and Professional Relations Bureau, Medical Society of the State of New York

Orlen J. Johnson, M.D., Bay City, Mich., Chairman, Public Relations Committee, Bay County Medical Society

Clinic Five, Parlor D

Topic: What is the best way to handle media (press, radio, TV) coverage of a state medical convention?

Discussion Leaders:

John L. Bach, Chicago, Director of Press Relations, American Medical Association

W. E. Syers, Austin, Public Relations Counsel, Texas Medical Association

Rowland B. Kennedy, Jackson, Executive Secretary, Mississippi State Medical Association

Clinic Six, Parlor F

Topic: How to enlist society support for its women's auxiliary. How to best utilize the PR potential of these groups.

Discussion Leaders:

Mrs. Neil W. Woodward, Oklahoma City, Chairman, Committee on Public Relations, Woman's Auxiliary to the American Medical Association

Thomas E. Walsh, New York, Field Representative, Public and Professional Relations Bureau, Medical Society of the State of New York

RECEPTION

5:30 p. m., French Room

Thursday, September 3

SOLVING MUTUAL MEDICAL SOCIETY–BLUE SHIELD PR PROBLEMS

9 a. m., Ballroom

Chairman: M. C. Smith, Lincoln, Executive Secretary, Nebraska State Medical Association

Symposium: What Can Be Done

Earl R. Thayer, Madison, Public Information Director, Wisconsin State Medical Society

L. T. Reed, Boston, Assistant Director, Massachusetts Medical Service

Donald L. Taylor, Des Moines, Field Secretary, Iowa State Medical Society

HEALTH FORUMS SPONSORED JOINTLY BY LOCAL NEWSPAPERS AND COUNTY MEDICAL SOCIETIES

10:15 a. m., Ballroom

Moderator: Arthur P. Tiernan, Evansville, Ind., Executive Secretary, Vanderburgh County Medical Society

Panel Discussion

N. Worth Gable, M.D., St. Petersburg, Fla., Pinellas County Medical Society

Stan Witwer, St. Petersburg, City Editor, St. Petersburg *Times*

Christopher J. McLoughlin, M.D., Atlanta, Public Relations Committee, Medical Association of Georgia

William I. Ray Jr., Atlanta, Managing Editor, Atlanta *Journal*

James Murray, Atlanta, Promotion Manager, Atlanta *Journal*

Questions from the Audience

LUNCHEON

12:15 p. m., French Room

What My Readers Write

W. W. Bauer, M.D., Health Columnist, King Features Syndicate

Theodore R. Van Dellen, M.D., Health Columnist, *Chicago Tribune* Syndicate

Herman N. Bundesen, M.D., Health Columnist, King Features Syndicate

PROBLEM SOLVING: HOW CAN MEDICINE'S STORY *BEST* BE TOLD?

2 p. m., Ballroom

Chairman: Hugh W. Brenneman, Lansing, Public Relations Counsel, Michigan State Medical Society

Audience will consider three problems:

Problem One: Case history based on the question: What is the best way to help the general public understand organized medicine?

Problem Two: Case history based on the question: What techniques can be used to help the general public understand the modern physician and how he should be used?

Problem Three: Case history based on the question: What can medicine do to help the general public understand the modern systems of medical care available to them?

Report to general assembly on suggested solutions.

THE INSTITUTE IN REVIEW

Leo E. Brown, Chicago, Director, Department of Public Relations, American Medical Association

RE-SHOWING OF TELEVISION FILMS

4:15 p. m., Ballroom

ADJOURN

5:30 p. m.

FEDERAL MEDICAL LEGISLATION

Guardianship of Indians

Senator Malone (R., Nev.) and Senator Butler (R., Neb.) have introduced a measure, S. 2515, which would give "complete emancipation of the Indians by the removal of guardianship over such Indians, and trusteeship over property, both real and personal, belonging to individual Indians and recognized tribes." Thus the integration of Indians would be complete. The functions of the Bureau of Indian Affairs in the Department of the Interior would be abolished, including hospitalization and medical care. This measure was referred to the Interior and Insular Affairs Committee.

Agency for the Handicapped

A separate agency for the physically handicapped would be established by S. 2570, proposed by Senators Murray (D., Mont.), Johnson (D., Colo.), Kilgore (D., W. Va.), Langer (R., N. Dak.), Magnuson (D., Wash.), Sparkman (D., Ala.), Neely (D., W. Va.), Humphrey (D., Minn.), Kefauver (D., Tenn.), and Lehman (D., N. Y.). This agency would be placed for housekeeping purposes in the Department of Labor. This bill is identical with H. R. 2096 (Hagen), H. R. 2147 (Tollefson), H. R. 2149 (Van Zandt), H. R. 2300 (Rhodes), H. R. 2342 (Wier), H. R. 2346 (Withrow), H. R. 2463 (McCormack), H. R. 2519 (Chudoff), H. R. 3177 (Kelley), H. R. 3188 (Perkins), H. R. 3291 (Celler), H. R. 3473 (Doyle), H. R. 4262 (Donohue), all previously reported. This measure was referred to the Committee on Labor and Public Welfare.

Extension of Social Security

Congressman Heller (D., N. Y.) has introduced H. R. 6664, and Congressman Price (D., Ill.) has introduced H. R. 6723, to broadly revise the old-age and survivors insurance program. These bills would not extend coverage to physicians or dentists. These bills are identical with S. 2260 (Lehman, D., N. Y., and 10 other Senators), H. R. 6034 (Dingell, D., Mich.), H. R. 6035 (Bolling, D., Mo.), H. R. 6036 (Roosevelt, D., N. Y.), H. R. 6041 (Celler, D., N. Y.), H. R. 6042 (Dodd, D., Conn.), H. R. 6043 (Eberharten, D., Pa.), H. R. 6044 (Elliott, D., Ala.), H. R. 6045 (Howell, D., N. J.), H. R. 6046 (Rhodes, D., Pa.), H. R. 6056 (Shelley, D., Calif.), H. R. 6072 (Holifield, D., Calif.), H. R. 6128 (Perkins, D., Ky.), H. R. 6162 (Dollinger, D., N. Y.), H. R. 6163 (Fine, D., N. Y.), H. R. 6164 (Klein, D., N. Y.), H. R. 6175 (Buckley, D., N. Y.), H. R. 6180 (Rodino, D., N. J.), H. R. 6215 (Addonizio, D., N. J.), H. R. 6229 (Metcalf, D., Mont.), all previously reported. These two measures were referred to the House Ways and Means Committeee.

Social Security Extension

Congressman Reed (R., N. Y.), Chairman of the House Ways and Means Committee, has introduced H. R. 6812 at the request of the administration. It would extend social security coverage to about 10,500,000 additional persons, 6,500,000 of whom would be brought into the system by mandatory action. Those required to participate if they earn $400 a year or more include physicians and interns (but not student nurses), dentists, osteopaths, veterinarians, chiropractors, naturopaths, optometrists, Christian Science practitioners, funeral directors, professional engineers, lawyers, architects, accountants, and other professional persons and farmers, plus farm workers and domestics earning $50 or more per quarter from one employer. Other groups, totaling about 4 million, would be offered coverage on a voluntary group basis. Such groups include state and local government employees now enrolled in retirement systems and ministers. The present law giving noncontributory wage credits of $160 a month to members of the armed forces would be continued to July 1, 1955. This bill was referred to the Ways and Means Committee.

Prepared by the Washington Office of the American Medical Association.

MEDICAL NEWS

CONNECTICUT

Course in Physiology.—This course, sponsored by the Stamford Academy of General Practice, will be given by the Post-Graduate Medical School of the New York University-Bellevue Medical Center in the auditorium of the Stamford Hospital under the direction of Dr. Maurice Bruger, New York. It is accredited by the American Academy of General Practice. The sessions (Sept. 22, Oct. 6 and 27, Nov. 3 and 24, Dec. 1 and 22, 1953, and Jan. 7, 1954) will start promptly at 8 p. m. Registration fee is $40. Registration forms may be obtained from Dr. Arthur Koffler, 218 Bedford St., Stamford, secretary, Stamford Academy of General Practice.

Personal.—Dr. C. Louis Fincke, Stamford, was recently appointed to membership on the Connecticut Medical Examining Board to fill the unexpired term of the late Dr. Wilmot C. Townsend, Hartford. Dr. Fincke, who is councilor to the Connecticut State Medical Society for the Fairfield County Medical Association, is director of medical services and vice-chairman of the medical board at Stamford Hospital and attending physician at St. Joseph Hospital, Stamford.——Dr. James E. Lewis Jr., assistant chief of surgery, Veterans Administration Hospital, Newington, and formerly assistant physician to President Truman, has been appointed assistant professor of surgery at the St. Louis University School of Medicine. Dr. Lewis has been affiliated with Peter Bent Brigham Hospital and the Children's Hospital in Boston and Children's Memorial Hospital, Chicago. He served in Europe during World War II and was decorated with the Bronze Star.

DELAWARE

Dr. Washburn Honored.—At the commencement exercises of the University of Delaware, Newark, Dr. Victor D. Washburn, Wilmington, president, Medical Society of Delaware, was awarded the honorary degree of doctor of public health. The citation pointed out that he has served the city of Wilmington as president of the board of education, president of the Department of Public Safety, president of the board of health, and health commissioner and that he has been state director of the Selective Service System and a member of the Delaware National Guard from which he was retired in 1946 with the rank of brigadier general. He is president of the Medical Society of Delaware and medical director of Memorial Hospital. In 1951, Dr. Washburn received the medal of the American Cancer Society in recognition of his important contributions in the control of cancer.

DISTRICT OF COLUMBIA

Practical Instruction for Interns and Residents.—Realizing the need for instruction in office management, medical ethics, medicolegal procedures, and other aspects of practical medical practice, the Medical Society of the District of Columbia has established, as a permanent feature of its activities, a series of question hours on the economics of medicine for interns and residents in that community. The first question hour held recently was attended by more than 90 young physicians who turned out to hear a panel of experts discuss a variety of subjects related to medical practice.

FLORIDA

Physicians Honored.—At its centennial commencement, the University of Florida conferred the honorary degree of doctor of science on Drs. William C. Thomas Sr., Gainesville, and Walter C. Payne Sr., Pensacola, past presidents of the Florida Medical Association, and on Drs. Turner Z. Cason, Jacksonville, and Warren W. Quillian, Coral Gables.

ILLINOIS

Tuberculosis Committee Named.—Governor Stratton has appointed the following as members of an advisory committee on tuberculosis control in Illinois: Drs. Walter S. Broker, East St. Louis; William J. Bryan, Rockford; Kenneth G. Bulley, Aurora; Warren W. Furey, Ernest E. Irons, Karl A. Meyer, David B. Radner, Leo P. A. Sweeney, and Edward A. Piszczek, Chicago; Jerome R. Head, Naperville; G. Daniel Morse, Peoria; Darrell H. Trumpe, Springfield; and Winston H. Tucker, Evanston. Ex-officio members are Dr. Otto L. Bettag, Chicago, director of the Illinois Department of Public Welfare, and Dr. Roland R. Cross, Springfield, director of the Illinois Department of Public Health.

Chicago

Dr. Compere to Head Department.—Dr. Edward L. Compere, associate professor of bone and joint surgery, Northwestern University Medical School, since 1941, has been named chairman of that department to succeed Dr. Philip Lewin, who will retire Aug. 31. Dr. Compere was previously chief of orthopedic service at Albert Merritt Billings Hospital and at the University of Chicago Clinics. He is affiliated with Wesley Memorial, Children's Memorial, Augustana, and Henrotin hospitals. He has served as a consultant in orthopedics at the U. S. Naval Hospital at Great Lakes, Ill., and to the Surgeon General of the Army. Since 1948, Dr. Compere has been a member of the A. M. A. House of Delegates.

Personal.—Dr. Myron Feld has been appointed an associate in psychiatry at the Chicago Medical School. Dr. Feld has been affiliated with the Veterans Administration hospitals in Hines and Downey, Ill.——Dr. Titus M. Johnson has gone to Africa to supervise the completion and operation of a 50-bed hospital being built in the Belgian Congo by the Evangelical Free Church of America. He plans to be gone about 18 months. This is his second visit to Africa as a medical missionary.——Dr. Roberto Ortiz, formerly of San Jose, Costa Rica, has been named recipient of the 1953 Northwestern graduate fellowship in pediatric surgery, the Florence Olmstead memorial fellowship, which will enable him to continue his work in pediatric surgery at Children's Memorial Hospital.

KENTUCKY

Society News.—The Kentucky Surgical Society recently elected Drs. W. Vinson Pierce, Covington, president; R. Arnold Griswold, Louisville, vice-president; and Francis M. Massie, Lexington, secretary and treasurer.

University News.—Faculty members at the University of Louisville School of Medicine, alumni, and friends of the late Dean John Walker Moore have initiated a drive to endow a new chair of medicine in his name. Members of the committee for the drive are Drs. Samuel A. Overstreet, chairman, J. Murray Kinsman, dean, and S. Spafford Ackerly, faculty member, all of Louisville. A John Walker Moore Annual Memorial lectureship also has been established at the school.——Emil Kotcher, Sc.D., associate professor of microbiology, has been given a leave of absence for an assignment with the U. S. P. H. S. as laboratory director of parasitology for the Special Technical and Economic Mission, Mutual Security Agency to the Associated States of Indo-China.——An award of $150 has been made to Drs. Avrom M. Isaacs, Harold F. Berg, and William M. Christophersen for the best scientific paper at the annual meeting in Havana, Cuba, of the Southeastern Section of the American Urological Association. The title of the contribution was "Localization of Radioactivity in the Urinary Bladder and the Regional Lymph Nodes."——The University of Louisville announces the following promotions: Dr. Walter S. Coe to associate professor of medicine and staff executive of the Louisville General Hospital and Drs. Paul Mapother and Maurice M. Best to assistant professor of medicine.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

MAINE

Meeting of Medico-Legal Society.—The Maine Medico-Legal Society held its annual meeting, Aug. 19, at Augusta House in Augusta under the presidency of Dr. Joseph E. Porter, Portland. The business meeting occupied the morning session. After luncheon there were remarks by Dr. Porter, Col. Francis J. McCabe, chief, state of Maine police, and Mr. Alexander A. LaFleur, attorney general. An address with pictures was presented by Dr. Richard Ford, assistant professor of legal medicine, Harvard Medical School, Boston.

MASSACHUSETTS

Society News.—The newly formed Greater Boston chapter of the Massachusetts Heart Association has elected Dr. Harold D. Levine, Boston, president; Dr. Edwin O. Wheeler, Boston, vice-president; and Dr. Egon E. Kattwinkel, Newton, secretary.

Lahey Postgraduate Assembly.—At the Lahey Clinic Postgraduate Assembly, Sept. 24-26, 10 subjects of interest to general practitioners and specialists in many fields will be presented in panel discussions by members of the various departments of the clinic. Emphasis will be placed on particular measures in diagnosis and treatment. Inquiries should be sent to the Lahey Clinic, 605 Commonwealth Ave., Boston 15.

Personal.—Dr. Francis D. Moore, surgeon-in-chief of the Peter Bent Brigham Hospital in Boston, delivered the second annual Herman G. Weiskotten lecture on "The Growth of Our Knowledge of Metabolism and Biology in Surgery" at the Syracuse Medical Alumni Association meeting May 28.——Dr. Benjamin Alexander, associate director of medical service at Beth Israel Hospital, Boston, has been appointed associate professor of medicine at Harvard Medical School and will serve in the dual role. Dr. Alexander has been teaching at Harvard Medical School since 1939.

MISSOURI

Society News.—At a special meeting of the St. Louis Medical Society, Sept. 25, 8:30 p. m., Dr. Melvin A. Casberg of the Armed Forces Medical Policy Council, Washington, D. C., will discuss "Military Medicine at the Department of Defense Level."

University News.—Dr. James W. Colbert Jr., dean of St. Louis University School of Medicine, recently delivered the annual William H. Vogt lecture, which is sponsored by the Alpha Mu Chapter, Alpha Kappa Kappa fraternity, in honor of the late Dr. William Hans Vogt, director of the department of obstetrics and gynecology, St. Louis University School of Medicine, from 1933 until his death in 1945.——Dr. Justin J. Cordonnier has joined the full-time faculty of Washington University School of Medicine, St. Louis, as professor of urology and head of the section of urology of the department of surgery. His offices will be at David P. Wohl Jr. Memorial Hospital, 4960 Audubon St. Dr. Cordonnier was associate professor of clinical genitourinary surgery at the school of medicine from 1950 to 1952. He served four years with the armed services medical corps.

MONTANA

Society News.—The Yellowstone Valley Medical Society has named Dr. Edward W. Gibbs, president; Dr. L. Clayton Allard, vice-president; Dr. Robert E. Mattison, secretary; and Dr. John J. Hammerel, treasurer (reelected). All officers are from Billings.

Surgeons Meet in Missoula.—The Montana chapter of the American College of Surgeons will meet in Missoula, Aug. 29. Guest speakers will be Dr. Walter C. MacKenzie, clinical professor of surgery, University of Alberta Faculty of Medicine, Edmonton, Canada, and Dr. Louis H. Edmunds, orthopedic staff, Virginia Mason Hospital, Seattle. Mr. John E. Corette, president of the Montana Power Company, guest speaker at the banquet, will talk on "The Physicians and the Power Companies in the National Picture." All physicians are cordially invited.

NEBRASKA

General Practitioners Meet.—A meeting of the Nebraska Academy of General Practice will be held Sept. 3 at the Fort Kearney Hotel in Kearney. The following program, open to all physicians, will be presented:

Lynn W. Thompson, Omaha, Regional Block Anesthesia (Slides and Models).
Charles W. McLaughlin Jr., Omaha, Hand Injuries: Surgical Management.
John D. Hartigan, Omaha, Management of Hypertension (New Drugs).
Frederick S. Webster, Lincoln, Congenital Hips: Their Management.
Paul D. Bruns, Denver, Problems in Prematurity.
Donald C. Campbell, Rochester, Minn., Problems Related to the Anemias.

NEVADA

Meeting of Reno Surgical Society.—The annual meeting of the Reno Surgical Society was scheduled for the Hotel Riverside, Aug. 20-22. Guest speakers and their first presentations include:

Hyrum R. Reichmann, Salt Lake City, Diagnosis and Treatment of Common Anorectal Lesions.
Max Samter, Chicago, Old and New Drugs and the Progress of Medicine.
Robert E. Gross, Boston, Surgery for Congenital Cardiovascular Anomalies.
Kenneth C. Swan, Portland, Ore., Emergency Care of Eye Injuries.
Russel H. Patterson, New York, Surgery of the Pancreas and Biliary Tract.
Fredrick J. Stare, Boston, Nutrition and the Surgeon.
Moore Moore, Memphis, Tenn., Intrinsic Causes of Shoulder Pain.
Erle Henriksen, Los Angeles, Problems of Stress Incontinence.
Owen H. Wangensteen, Minneapolis, The Extended Operation for Cancer.
Mr. Perry Burgess, president, General Leonard Wood Memorial (American Leprosy Foundation), New York, The Orphan of Diseases.

A round table discussion by all members of the speakers panel ended the meeting. Dr. John W. Cline, San Francisco, Past President of the American Medical Association, served as moderator.

NEW YORK

Hutchings Memorial Lecture.—Dr. Bernard C. Glueck Jr., director of the Sex Offender Research Project of the New York State Department of Mental Hygiene and supervising psychiatrist at Sing Sing Prison, Ossining, will deliver the annual Hutchings Memorial lecture ("Psychodynamic Patterns in the Sex Offender"), Oct. 5, in the auditorium of the State University of New York College of Medicine at Syracuse. The lectures are cosponsored by the Dr. Richard H. Hutchings Memorial Trust Fund Committee, the Onondaga County Medical Society, the Syracuse Academy of Medicine, and the State University of New York College of Medicine at Syracuse.

Personal.—Dr. Giles F. Filley, Associated College of Physicians, has been appointed head of the physiology department of the Trudeau Sanatorium and Foundation in Saranac Lake, succeeding Dr. George W. Wright, who has resigned to become director of a department of research at St. Luke's Hospital in Cleveland. Dr. Filley has been associated with Dr. Wright at Trudeau since 1947.——Dr. Irving N. Holtzman, Brooklyn, has been promoted to attending dermatologist at the Jewish Hospital of Brooklyn to succeed the late Dr. Jacob Skeer. Dr. Holtzman is also associate clinical professor of dermatology and syphilology at New York University College of Medicine-Bellevue Medical Center and attending dermatologist at the Kingston Avenue and John E. Jennings hospitals and the Jewish Sanitarium and Hospital for Chronic Diseases, Brooklyn.

New York City

Occupational Medicine Course.—A series of lectures on occupational medicine will be given 9-10 a. m. on Saturdays beginning Sept. 19 in amphitheater A, Columbia University College of Physicians and Surgeons, 630 W. 168th St., New York 32, by members of the staff of the division of occupational medicine of the school of public health. Members of the medical and allied professions are invited to attend. There will be no formal registration and no tuition fee. The schedule is as follows:

Sept. 19, History, Scope, Objectives, and Practice of Occupational Medicine.
Sept. 26, Industrial Toxicology—General Principles.
Oct. 3, Toxic Metals, I.
Oct. 10, Toxic Metals, II.
Oct. 17, Toxic Dusts.
Nov. 7, Toxic Gases.
Nov. 14, Occupational Dermatoses and Infections.
Nov. 21, Ventilation; Lighting; Noise.
Nov. 28, Elementary Nuclear Physics; Radiation Hazards.
Dec. 5, Workmen's Compensation.
Dec. 12, Written Examination (optional).

The order in which the topics are presented may be modified depending on the availability of lecturers.

Dr. Fitzgerald Named Professor of Pathology.—Dr. Patrick James Fitzgerald, assistant pathologist, Memorial Center for Cancer and Allied Diseases, and assistant, department of physics, Sloan-Kettering Institute for Cancer Research, has been appointed chairman of the department of pathology at the State University of New York College of Medicine in Brooklyn. Dr. Fitzgerald, who is also assistant professor of pathology at the Sloan-Kettering division of Cornell University Medical College, succeeds Dr. Jean R. Oliver, who has been granted special leave by the state university to engage in research for the Armed Forces Epidemiological Board on the renal lesion of epidemic hemorrhagic fever. Dr. Fitzgerald has been affiliated with Boston City Hospital and Tufts College Medical School, Boston. At the Memorial Center for Cancer and Allied Diseases, he was a National Cancer Institute research fellow in several studies, including tumor pathology, x-ray absorption, and isotope techniques. From 1949 to 1950, he served as a Sloan-Kettering Institute fellow at the Institute for Cell Research, Karolinska Institutet, Stockholm, Sweden, on studies in ultraviolet microscopy and on x-ray absorption. From 1943 through 1946, he served as pathologist and tropical disease officer for several U. S. Naval hospitals.

OHIO

Community Honors Physician.—The mayor of New Bremen declared, by proclamation, July 30 "Dr. F. F. Fledderjohann Day," in honor of Dr. Ferdinand F. Fledderjohann who, during his 50 years of medical practice, "exemplified the virtues of kindliness, unselfishness, generosity, honesty, and patience, together with a brilliant background of medical knowledge. . . ."

Popular Health Television Shows.—The Cleveland Health Museum and the Academy of Medicine of Cleveland recently used television as the medium for presenting 16 one-half hour "Prescription for Living" shows sponsored by the Standard Oil Company of Ohio. Each show, handling one subject, utilized a typical Ohio family whose lack of understanding of medical practices made it a foil for the guest physician from the Academy of Medicine, who exposed the common fallacies on the subject. Health museum exhibits were employed as visual aids. Interest in the programs was shown in the mail requests for the free digests offered, the highest, 2,100, being received for the program, "Shorter Waistline—Longer Lifeline." Sample digests sent to teachers of Cleveland public schools brought requests from 3,200 teachers to receive the digests weekly. Other school systems also requested them. The television show "Prescription for Living" will be resumed in September for 26 weeks. Limited numbers of digests of the first series are available from the Cleveland Health Museum, 8911 Euclid Ave., Cleveland 6.

PENNSYLVANIA

Benjamin Rush Awards.—The Medical Society of the State of Pennsylvania has announced the winners of the Benjamin Rush Award presented annually to a layman and a group performing outstanding services in the field of health. Winners were selected from a group of 62 nominees submitted by the individual county medical societies in Pennsylvania. The group award was won by the Committee of Five (Berwick Blood Procurement Plan of Columbia County) whose efforts made it possible for the city of Berwick to more than double its annual blood quota. T. Ellwood Sones, Mt. Jewett, county school superintendent in Centre County, won the individual award for meritorious work in rural health, including establishment of the first county-wide rural school nurse program in Pennsylvania.

Personal.—Dr. Max B. Lurie, associate professor of experimental pathology at the Henry Phipps Institute for the Study, Treatment and Prevention of Tuberculosis, an affiliate institute of the University of Pennsylvania, Philadelphia, has won the Claude Bernard medal bestowed by the University of Montreal, Canada. The award, given after Dr. Lurie delivered a series of lectures at the University of Montreal before the Institute of Experimental Medicine and Surgery and the Institute of Microbiology, was made on the basis of Dr. Lurie's work on genetic resistance to tuberculosis, the role of sex hormones in resistance, the effect of cortisone and corticotropin (ACTH) on the pathogenesis of tuberculosis, and the nature of acquired resistance in the light of hormonal influences on native resistance.——Drs. Jacob A. Trexler, Lehighton, Roger P. Batchelor, Palmerton, and C. Howard Moses, Sharon, recently received 25 year awards for their service to crippled children. The awards were presented at testimonial dinners given by county crippled children's societies.

Pittsburgh

Narcotic Violation.—Dr. Wayne E. Backus pleaded guilty in the U. S. District Court at Pittsburgh to violation of USC Title 18, Section 494. On June 17 sentence was suspended, and he was placed on probation for a period of one year and ordered to pay the costs of the prosecution ($49) and was fined $100. According to the Bureau of Narcotics, it was the opinion of the court that Dr. Backus should be permitted to pursue the practice of medicine and surgery during the period of his probation.

Scaife Fellowships in Pathology.—The University of Pittsburgh announces the establishment of the Sarah Mellon Scaife fellowships in pathology. Under the fellowships, which will provide experience in research, teaching, and diagnostic pathology, three years will be spent in the department of pathology, University of Pittsburgh, and arrangements will be made for one year at another medical center of the applicant's choice. One fellow will be appointed each year for a four year term, with annually increased stipends as follows: $3,000, $3,300, $3,700, and $4,000. The applicant, a graduate of an approved medical school, must apply by Nov. 1 for a fellowship beginning July 1 of the following year. Notice of selection will be made by Dec. 15. Further information and application forms are available from Dr. Frank J. Dixon, Department of Pathology, University of Pittsburgh, Pittsburgh 13.

SOUTH CAROLINA

Joint Meeting of Ophtho-Otolaryngologists.—A joint meeting of the South Carolina Society of Ophthalmology and Otolaryngology and the North Carolina Eye, Ear, Nose and Throat Society will be held at the Francis Marion Hotel, Charleston, Sept. 14-16. Out-of-state speakers include: Drs. Wayne B. Slaughter, Derrick T. Vail, and John R. Lindsay, Chicago; Theodore E. Walsh, St. Louis; David G. Cogan, Boston; and R. Townley Paton, New York. There will be a panel discussion on vertigo with Dr. E. Charles Kunkle, Duke University School of Medicine, Durham, N. C., as guest neurologist and Dr. Vince Moseley, Medical College of South Carolina, Charleston, as guest internist. For information write Dr. George B. Ferguson, McPherson Hospital, Durham, N. C., or Dr. Roderick Macdonald, 330 E. Main St., Rock Hill.

Annual Scientific Meeting.—The Self Memorial Hospital will hold its annual scientific meeting at Greenwood, Aug. 29. Dr. Manuel E. Lichtenstein, Chicago, will speak on "The Essential Differences Between the Two Halves of the Colon" and "Improving End Results Following Cholecystectomy." Dr. Joseph G. Kostrubala, Chicago, will discuss "Carcinoma of Head and Neck with Emphasis on Intraoral Diagnosis" and "Problems of Maxillofacial Surgery." Presentations will be made by Dr. David F. James, Emory University, Ga. ("Differential Diagnosis of Jaundice"); Dr. Willard H. Parsons, Vicksburg, Miss. ("Cancer of the Breast"); and George C. Albright, D.D.S., Greenville ("Use of General Anesthesia in Office Practice of Oral Surgeon"). A social hour at the Moose Club preceding the banquet, 7:30 p. m., at the Oregon Hotel will be addressed by Mr. W. C. Walkup, Knoxville, Tenn. Dr. Lawrence P. Thackston, Orangeburg, former president of the South Carolina Medical Association, will present the association's plaque to Mr. J. C. Self.

UTAH

Narcotic Violation.—Dr. James W. Nixon, 593 N. University Ave., Provo, pleaded guilty to an indictment charging violation of USC Title 26, Section 2554, in the U. S. District Court at Salt Lake City, and on April 15 was fined $100 on counts 1 to 5 inclusive and on count 6 was placed on probation for five years.

Personal.—Dr. Warren A. Colton, manager of the Veterans Administration Hospital, Salt Lake City, was recently honored at a public reception in the hospital auditorium on the occasion of his retirement at the age of 70.——Herbert L. Borison, Ph.D., assistant professor of pharmacology, University of Utah College of Medicine, Salt Lake City, recently received from the American Society for Pharmacology and Experimental Therapeutics the John J. Abel award for studies on the pharmacology and physiology of brain stem functions with special reference to respiration, circulation, and vomiting.

Dr. Calderwood Retires as Medical Director.—Dr. William R. Calderwood, Salt Lake City, medical director of the Beneficial Life Insurance Company since its organization, has retired from that position but will continue to serve as a member of the board of directors. Dr. Calderwood, who is a past president of the Utah State Medical Society, has been president of the hospital board of Latter Day Saints Hospital, Logan, president of the board of directors of the Medical Arts Building, a member of the board of the state mental hospital, and president of the Emeritus Club of the University of Utah, Salt Lake City. Succeeding him as medical director is Dr. Maurice J. Taylor.

WISCONSIN

Dr. Bailey Day.—Dr. Mark A. Bailey, Fennimore, who has served his community for 50 years, was honored at celebrations sponsored by the Kiwanis Club, the American Legion post and its auxiliary, and the Fennimore city council. The celebration included a parade, speeches, and a social hour. Dr. Bailey, who started practice in association with his father, the late Dr. A. B. Bailey, in May of 1903, has served as mayor, as health officer, and in community organizations.

GENERAL

Hearing Society to Move Headquarters.—The American Hearing Society has announced plans to move its national headquarters from Washington, D. C., where it has been located since 1922, to Columbus, Ohio. Affiliated with the society, a nonprofit, social service organization founded in 1919, are 115 local chapters in 34 states, the District of Columbia, and Canada. The organization, which has as its objectives the prevention of deafness, conservation of hearing, and rehabilitation of the hard of hearing, is supported by membership dues from persons and chapters, and contributions from persons and community chests. It is anticipated that operational costs will be lowered by the proposed move.

March of Dimes Establishes New Record.—Mr. Basil O'Connor, president of the National Foundation for Infantile Paralysis, announces that a record amount of $51,500,000 was contributed to the 1953 March of Dimes, an increase of 24% over the 1952 collection. The new record shows contributions of 34 cents per capita against last year's record of 27.5 cents per capita for the entire nation. All states exceeded their 1952 contributions. Nevada ranked first with an average per capita contribution of 94 cents, Wyoming second with 69 cents, and Idaho third with 65 cents. Alaska led all territories with a per capita average of 79 cents. In dollar contributions New York state took first place with $5,098,000. California residents contributed $4,426,000 and Ohio $3,074,000.

Life Insurance Medical Research Fellowships.—The Life Insurance Medical Research Fund announces that applications for awards available July 1, 1954, will be received as follows: (1) postdoctoral research fellowships ($3,300-$4,500), until Oct. 31, preference being given to those who wish to work on cardiovascular function and disease or related fundamental problems and (2) grants to institutions in aid of research on cardiovascular problems, until Nov. 15. Support is available for physiological, biochemical, and other basic work broadly related to cardiovascular problems as well as for clinical research in this field. Information may be obtained from the Scientific Director, Life Insurance Medical Research Fund, at the new headquarters, 345 E. 46th St., New York 17.

Cancer Society Approves Training Institutes.—The American Cancer Society announces that three additional institutions have been approved by its board of directors for training American Cancer Society fellows in exfoliative cytology. These institutions and the directors of the laboratory of exfoliative cytology are Memorial Center for Cancer and Allied Diseases, New York (Drs. Howard Richardson and Emerson Day), Roosevelt Hospital, New York (Dr. Walter W. Brandes), and Jewish Hospital of St. Louis, St. Louis, Mo. (Dr. Herman T. Blumenthal). Further information concerning the society's support in training qualified pathologists in this field may be procured from Dr. Brewster S. Miller, director, Professional Education Section, American Cancer Society, 47 Beaver St., New York 4.

Meeting of Bacteriologists.—The Society of American Bacteriologists held its 53rd general meeting as guests of the Northern California-Hawaii Bacteriologists at the Palace Hotel, San Francisco, Aug. 10-14, under the presidency of Dr. Gail M. Dack, Chicago. The 100 papers presented before the medical division were devoted to virus multiplication, pathogens of animal origin, viruses and rickettsia, radiation, viruses and hemagglutination, enteric bacteriology, immunology, mycobacteria, antibiotics, and miscellaneous studies. Symposiums were held on "Energy Utilization in Synthetic Reactions," "Radiation Effects on Cells and Bacteria," "History of Bacteriology," "Role of Infection in Radiation Injury," and "The Actinomycetes." At the opening session Monday evening, Dr. William M. Stiles, Berkeley, Calif., delivered a special lecture entitled "A Challenge for Modern Bacteriologists."

Retina Service Fellowship.—This fellowship, created by the Retina Foundation, will be granted to a young ophthalmologist from the United States or abroad who wishes to be trained for 6 to 12 months at the retina service of the Massachusetts Eye and Ear Infirmary, Boston. Remuneration is $1,000 per annum plus room, board, and laundry at the infirmary. Training covers methods of examination of the extreme periphery of the fundus and the vitreous, use of the indirect stereoscopic ophthalmoscope and scleral depressor, and surgical procedures in cases of retinal detachment. Original research of a clinical nature will be encouraged. Candidates must have completed a residency in ophthalmology or have had comparable training.

Applications, accompanied by a biography and at least two references, should be mailed to Dr. Edwin B. Dunphy, Chief of Ophthalmology, Massachusetts Eye and Ear Infirmary, 243 Charles St., Boston 14.

Grant for Study of Hospital Design.—The Rockefeller Foundation has made a grant of $140,000 to the American Psychiatric Association, Washington, D. C., for the study of mental hospital design, construction, and equipment. In cooperation with the American Institute of Architects, the American Psychiatric Association is planning the development of mental hospitals in the light of current needs. It has been estimated that 6 billion dollars could usefully be spent in the next 10 years to provide the space needed and to replace outworn equipment. A committee of the two professions will give full time to studying the best available examples of mental hospital construction in this and in other countries and to conferring with hospital superintendents on present trends in the care of the mental patient. This committee, to be financed for two years by the above grant, will draw up sample plans and provide advisory service to authorities responsible for new construction.

Conference on Food Protection.—The first National Conference on Food Protection, recently held at Ann Arbor, Mich., was sponsored by the National Restaurant Association and public health officials, under the auspices of the National Sanitation Foundation, with headquarters at the University of Michigan School of Public Health. The conference considered the need for a more uniform approach to the problems of preparing and serving foodstuffs and beverages in a sanitary manner in the home, at schools, in hospitals, at church and other "socials," in industry, and at all public eating establishments. Special committees were appointed during the conference to recommend action in two principal areas: (1) launching a nation-wide sanitation educational program for the public, sanitation officials, and food handlers on the safest and best methods to protect food and (2) working toward national uniformity in official health regulations and ordinances governing food protection.

Accidental Fatalities Among Young Children.—According to the Metropolitan Life Insurance Company, accidents currently account for one-fourth of all deaths among children at ages 1 to 4 insured by them in the United States and Canada and take a far higher toll than any other cause of death. In their study of various types of fatal injuries among the insured children, motor vehicle accidents accounted for 35.8% of all injuries; conflagrations and burns by other means, 28.2%; drownings, 11.3%; poisoning, 5.1%; falls, 4.6%; choking by objects or food, 4.2%; and other causes, 10.8%. In association with the committee on accident prevention of the American Academy of Pediatrics, the company has prepared a booklet entitled "A Formula for Child Safety," which discusses the typical development and behavior of preschool children, identifies safety hazards in and about the home, and suggests precautions to avert accidents. Copies of the booklet are distributed to parents and others without charge by the company's representatives and at its offices.

Society News.—The New England Society of Anesthesiologists recently elected Drs. Stevens J. Martin, Hartford, Conn., president; Elihu Saklad, Providence, R. I., vice-president; and Francis J. Audin, Boston, secretary-treasurer. On Oct. 16, the society will hold a joint meeting with the Massachusetts Society of Anesthesiologists in Boston.——At its annual meeting in New Orleans the Association of Bone and Joint Surgeons elected Drs. Frederick F. Teal Jr., Lincoln, Nebr., president; Edward T. Evans, Minneapolis, first vice-president; Louis W. Breck, El Paso, Tex., second vice-president; Lee C. Schlesinger, New Orleans, secretary; and Dana M. Street, Memphis, Tenn., treasurer. The next annual meeting will be held in Augusta, Ga.——At the annual meeting in New York, the American Medical Women's Association, Inc., elected Drs. Judith E. Ahlem, Livermore, Calif., president; Camille Mermod, Newark, N. J., president-elect; Minnie L. Maffett, Dallas, Tex., and Ruth E. Lesh, Fayetteville, Ark., vice-presidents; Elizabeth H. R. Fischer, Chicago, treasurer; Helena Hoelscher, Cleveland, assistant treasurer; Dorothy A. Haasch Chess, Ventura, Calif., recording secretary; and Charna G. Perry, Sausalito, Calif., corresponding secretary.

Meetings on Physical Medicine and Rehabilitation.—The American Society of Physical Medicine and Rehabilitation will hold its annual session at the Palmer House, Chicago, Aug. 31. The meeting will open with a discussion on "Method of A. M. A. Residency Approval" by Dr. Edward H. Leveroos, director, division of hospitals and graduate medical education, A. M. A. Council on Medical Education and Hospitals. Dr. Walter M. Solomon, Cleveland, will serve as moderator for a panel discussion on "New Concepts in Treatment of Rheumatic Diseases," in which Dr. Gordon M. Martin, Rochester, Minn., will discuss rheumatoid arthritis; Dr. Arthur L. Watkins, Boston, degenerative joints; and Dr. Frances Baker, San Mateo, Calif., nonarticular rheumatism.

The American Congress of Physical Medicine and Rehabilitation will hold its annual session at the Palmer House, Aug. 31 to Sept. 4, under the presidency of Dr. Walter M. Solomon, Cleveland. Tuesday morning a preliminary report on "Results of a Combined Medical and Rehabilitation Program in Tuberculosis" will be presented by Albert Haas, New York (by invitation), Dr. Howard A. Rusk, New York, and Morton Zivan, M.A., New York (by invitation). Wednesday morning there will be a symposium on ultrasound. Wednesday afternoon the third John Stanley Coulter Memorial lecture, "A Medical Physicist Looks at Physical Medicine," will be presented by invitation by Otto Glasser, Ph.D., Cleveland. Sixty-two papers are scheduled for presentation, and 10 will be read by title.

Awards Announced by Chest Physicians.—At the annual president's banquet in New York, the American College of Chest Physicians awarded to Dr. Helen B. Taussig, physician-in-charge, Cardiac Clinic, Harriet Lane Home, Johns Hopkins Hospital, Baltimore, the gold medal of the college for her pioneering work in congenital diseases of the heart. Essay awards were made as follows: Dr. A. Link Koven, Philadelphia, $250 and first prize certificate for "Bronchogenic Carcinoma in Chromate Workers"; Dr. Adrian M. Sabety, East Orange, N. J., second prize certificate for "Contralateral Spontaneous Pneumothorax as a Complication of Intrathoracic Operations"; and Dr. William R. Halliday, Salt Lake City, third prize certificate for "Endomyocardial Fibroelastosis."

Railroad Expands Medical Service.—Dr. Norbert J. Roberts, Philadelphia, medical director of the Pennsylvania Railroad, announces expansion and reorganization of the medical department, involving a staff of 56 full time physicians, about 350 consultant physicians and surgeons, and additional health maintenance centers and medical equipment. The program will encompass all phases of industrial medicine, including health education, preventive medicine, frequent physical examinations when indicated, and closer control of working conditions. It will supplement, but in no way replace, the care employees receive from their family physicians.

Dr. Alexander M. W. Hursh, Philadelphia, the railroad's chief medical examiner since 1945, has been advanced to assistant medical director. Dr. Charles W. Asbury, Hamilton, Ohio, formerly a fellow in the department of preventive medicine and industrial health, University of Cincinnati College of Medicine, has been appointed regional medical officer for the central region at Pittsburgh. Dr. Donald L. Glenn, staff internist at Carle Memorial Hospital and Clinic and McKinley Memorial Hospital, Urbana, Ill., becomes regional medical officer for the eastern region at Philadelphia. Dr. Nathaniel J. Fine, district medical examiner at Altoona, Pa., is advanced to medical officer, Altoona Works.

Dr. Roberts also announced appointment of the following medical staff specialists in internal medicine: at Philadelphia, Dr. William M. Woodward, until recently in private practice at Bristol, Pa.; at Altoona, Dr. David W. Bishop, former chief of medicine at the U. S. Marine Hospital, Mobile, Ala.; and, at New York, Dr. Patrick H. Curran, formerly on the staff of Bellevue Hospital, New York. Divisional and local medical officers are to be appointed within the next few weeks.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories, and possessions in the weeks ended as indicated:

CORRECTIONS

Acrodermatitis Enteropathica.—In the article by this title in The Journal, June 6, 1953, page 512, second line from the top, the words "four times a day" should follow "the administration of 210 mg."

Method and Machine for Resuscitation of the Newborn.—In the article by this title in The Journal, Aug. 1, 1953, page 1333, the following credit lines were inadvertently omitted: Dr. R. C. Ritchie, Department of Pathology, Hospital for Sick Children, Toronto, obtained the tracheal catheter measurements in a series of autopsies. Mr. Percy Hermant and his staff at the Imperial Surgical Company assumed the cost of building the pilot model of the machine and gave active cooperation and keen interest as well. Paul Aldwyn of the same company supplied technical assistance.

MEETINGS

American Medical Association: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1953 Clinical Session, St. Louis, Dec. 1-4.

1954 Annual Session, San Francisco, June 21-25.

1954 Clinical Session, Miami, Florida, Nov. 30-Dec. 3.

1955 Annual Session, Atlantic City, N. J., June 6-10.

1955 Clinical Session, Boston, Nov. 29-Dec. 2.

National Conference on Physicians and Schools, Moraine-on-the-Lake Hotel, Highland Park, Ill., Sept. 30-Oct. 2. Dr. W. W. Bauer, 535 N. Dearborn St., Chicago 10, Director.

Public Relations Institute, Drake Hotel, Chicago, Sept. 2-3. Mr. Leo E Brown, 535 North Dearborn St., Chicago 10, Director.

American Academy of Ophthalmology and Otolaryngology, Palmer House, Chicago, Oct. 12-16. Dr. W. L. Benedict, 100 First Avenue Bldg., Rochester, Minn., Executive Secretary.

American Academy of Pediatrics, Municipal Auditorium, Miami, Fla., Oct. 6-9. Dr. E. H. Christopherson, 610 Church St., Evanston, Ill., Secretary.

American Association of Medical Clinics, Congress Hotel, Chicago, Oct. 9-11. Dr. Edwin P. Jordan, P. O. Box 114, Charlottesville, Va., Executive Director.

American Association of Medical Record Librarians, Palace Hotel, San Francisco, Oct. 5-9. Miss Doris Gleason, 510 N. Dearborn St., Chicago 10, Executive Secretary.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, The Homestead, Hot Springs, Va., Sept. 10-12. Dr. William F. Mengert, 2211 Oak Lawn Ave., Dallas, Texas, Secretary.

American Association for the Surgery of Trauma, Drake Hotel, Chicago, Oct. 1-3. Dr. James K. Stack, 700 North Michigan Blvd., Chicago, Secretary.

American College of Surgeons, Conrad Hilton Hotel, Chicago, Oct. 5-9. Dr. Michael L. Mason, 40 East Erie St., Chicago, Secretary.

American Congress of Physical Medicine, Palmer House, Chicago, Aug. 31-Sept. 4. Dr. Walter J. Zeiter, 30 North Michigan Ave., Chicago 2, Executive Director.

American Dietetic Association, Los Angeles, Aug. 24-28. Miss Ruth M. Yakel, 620 N. Michigan Ave., Chicago 11, Executive Secretary.

American Fracture Association, Mission Inn, Riverside, Calif., Oct. 12-15. Dr. H. W. Wellmerling, 120 S. LaSalle St., Chicago 3, Secretary.

American Hospital Association, San Francisco, Aug. 31-Sept. 3. Mr. George Bugbee, 18 East Division St., Chicago 11, Executive Director.

American Medical Writers' Association, Elk's Club, Springfield, Ill., Sept. 23. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

American Roentgen Ray Society, Netherland Plaza, Cincinnati, Sept. 29-Oct. 2. Dr. Barton R. Young, Germantown Hospital, Philadelphia 44, Secretary.

American Society of Anesthesiologists, Olympic Hotel, Seattle, Oct. 6-9. Dr. J. Earl Remlinger Jr., Room 1101, 188 W. Randolph St., Chicago, Secretary.

American Society of Clinical Pathologists, Drake Hotel, Chicago, Oct. 12-16. Dr. Clyde G. Culbertson, 1040 W. Michigan St., Indianapolis, Secretary.

American Society for Pharmacology and Experimental Therapeutics, Fall Meeting, Yale University, New Haven, Conn., Sept. 7-9. Dr. Carl C. Pfeiffer, 1853 West Polk St., Chicago 12, Secretary.

Association of Life Insurance Medical Directors of America, Hotel Statler, New York, Oct. 14-16. Dr. Henry B. Kirkland, P. O. Box 594, Newark 1, N. J., Secretary.

Association of Medical Illustrators, Sheraton Hotel, Baltimore, Oct. 5-7. Miss Evelyn J. Erickson, 1512 St. Antoine St., Detroit 26, Secretary.

Biological Photographic Association, Hotel Statler, Los Angeles, Aug. 31-Sept. 3. Miss Jane H. Waters, 533 West 57th St., New York 19, Secretary.

Central Neuropsychiatric Association, Claypool Hotel, Indianapolis, Oct. 15-17. Dr. Hamilton Ford, 112 North Blvd., Galveston, Texas, Secretary.

College of American Pathologists, Drake Hotel, Chicago, Oct. 12-16. Dr. Harry P. Smith, 203 N. Wabash Ave., Chicago 1, Secretary.

Colorado State Medical Society, Shirley-Savoy Hotel, Denver, Sept. 29-Oct. 2. Mr. Harvey T. Stethman, 835 Republic Bldg., Denver 2, Executive Secretary.

Delaware, Medical Society of, Hotel du Pont, Wilmington, Oct. 12-14. Dr. Andrew M. Gehret, 822 North American Bldg., Secretary.

District of Columbia, Medical Society of the, Hotel Statler, Washington, Oct. 5-7. Mr. Theodore Wiprud, 1718 M St. N.W., Washington 6, Secretary.

Gerontological Society, Mark Hopkins Hotel, San Francisco, Aug. 25-27. Dr. Nathan W. Shock, Baltimore City Hospitals, Baltimore 24, Secretary.

Gulf Coast Clinical Society, Admiral Semmes Hotel, Mobile, Ala., Oct. 15-16. Dr. William J. Atkinson Jr., 1217 Government St., Mobile 20, Ala., Secretary.

Gulf Coast Conference on Industrial Health, Shamrock Hotel, Houston, Tex., Oct. 1-3. Dr. Sidney Schnur, 411 Medical Arts Bldg., Houston 2, Tex., Vice Chairman.

Kansas City Southwest Clinical Society, Kansas City, Mo., Sept. 28-Oct. 1. Dr. W. H. Algie, 825 North 7th Street, Kansas City, Kans., Secretary.

Kentucky State Medical Association, Brown Hotel, Louisville, Sept. 22-24. Dr. Bruce Underwood, 620 South Third St., Louisville 2, Secretary.

Michigan State Medical Society, Pantlind Hotel and Civic Auditorium, Grand Rapids, Sept. 23-25. Dr. L. Fernald Foster, 606 Townsend St., Lansing 15, Secretary.

Mississippi Valley Medical Society, Springfield, Ill., Sept. 23-25. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

Montana Medical Association, Northern Hotel, Billings, Sept. 17-20. Mr. L. R. Hegland, 104 North Broadway, Billings, Executive Secretary.

National Gastroenterological Association, Hotel Biltmore, Los Angeles, Oct. 12-17. Dr. A. Xerxes Rossien, 1819 Broadway, New York 23, Secretary.

Neurosurgical Society of America, The Broadmoor, Colorado Springs, Colo., Sept. 23-27. Dr. C. D. Hawkes, 22 North Manassas St., Memphis 5, Tenn., Secretary.

Nevada State Medical Association, Carter Hotel, Elko, Sept. 24-26. Dr. William A. O'Brien III, 505 Chestnut St., Reno, Secretary.

New Hampshire Medical Society, Equinox House, Manchester, Vt., Oct. 4-6. Dr. Deering G. Smith, 44 Chester St., Nashua, Secretary.

Northern Minnesota Medical Association, Fergus Falls, Aug. 28-29. Dr. C. L. Oppegaard, Crookston, Secretary.

North Pacific Society of Internal Medicine, Harrison, B. C., Canada, Sept. 18-19. Dr. Clarence C. Pearson, 1115 Terry Ave., Seattle 1, Wash., Secretary.

North Texas-Southern Oklahoma Fall Clinical Conference, Wichita Falls, Texas, Sept. 16. Dr. C. H. Wilson, 1300 Eighth St., Wichita Falls, Texas, Secretary.

Congress of the International Society of Surgery, Lisbon, Portugal, Sept. 14-20. Dr. L. Dejardin, 141, rue Belliard, Brussels, Belgium, General Secretary.

Interim Meeting, Aero Medical Association, University of Brussels Medical School, Brussels, Belgium, Sept. 24-27. Dr. Andre Allard, Medical Director of SABENA, 145 Rue Royale, Brussels, Belgium, Secretary.

International Cancer Congress, Sao Paulo, Brazil, July 23-29, 1954. Prof. A. Prudente, 171 rua Benjamin Constante, Sao Paulo, Brazil, President.

International Conference on Thrombosis and Embolism, Basle, Switzerland, July 15-19, 1954. Dr. W. Merz, Chief Medical Officer, Gynecological Clinic, University of Basle, Basle, Switzerland, Hon. Secretary.

International Congress of the European Society of Haematology, Amsterdam, Holland, Sept. 8-12. Dr. M. C. Verloop, Maliesingle 15, Utrecht, Holland, Secretary.

International Congress on Genetics, Bellagio, Italy, August 24-31. Prof. C. Barigozzi, Instituto de Genetica, Universita de Milano, 10 via Celoria, Milan, Italy, Secretary.

International Congress on Group Psychotherapy, Toronto, Ont., Canada, Aug. 12-14, 1954. Dr. J. L. Moreno, Room 327, 101 Park Ave., New York 17, N. Y., U. S. A., Director of Organizing Committee.

International Congress of Hippocratic Medicine, Evian, France, Sept. 3-6. Prof. P. Delore, 13, rue Jarente, Lyon, France, Secretary-General.

International Congress of Hydroclimatism and Thalassotherapy, Dubrovnik, Yugoslavia, May 8-16, 1954. Prof. C. Plavsic, Zeleni Venac 1, Belgrade, Yugoslavia, Secretary General.

International Congress of International College of Surgeons, Sao Paulo, Brazil, April 26-May 2, 1954. Dr. Max Thorek, 1516 Lake Shore Drive, Chicago, Illinois, U.S.A., Secretary-General.

International Congress of Logopedics and Phoniatrics, Zurich, Switzerland, Sept. 1-5. Dr. Deso A. Weiss, 115 East 86th St., New York 28, N. Y., U. S. A., General Secretary.

International Congress on Mental Health, University of Toronto, Toronto, Ontario, Canada, Aug. 14-21, 1954. For information write: Executive Officer, International Congress on Mental Health, 111 St. George St., Toronto, Ontario, Canada.

International Congress of Microbiology, Rome, Italy, Sept 6-12. For information write: Dr. V. Puntoni, Citta Universitaria, Rome, Italy.

International Congress on Obstetrics and Gynecology, Geneva, Switzerland, July 26-31, 1954. Dr. H. de Watteville, Maternité Hôpital Cantonal, Geneva, Switzerland, President.

International Congress of Paediatrics, Havana, Cuba, Oct. 12-17. Prof. *Felix Hurtado, 5a Avenue 124, Miramar, Havana, Cuba, President.*

International Congress of Psychology, Montreal, Canada, June 7-12, 1954. For information write: Prof. H. S. Langfeld, International Union of Scientific Psychology, Eno Hall, Princeton University, Princeton, N. J., U. S. A.

International Congress for Psychotherapy, Zurich, Switzerland, July 21-24, 1954. Dr. H. K. Fierz, Theaterstrasse 12, Zurich 1, Switzerland, Secretary General.

International Congresses of Tropical Medicine and Malaria, Istanbul, Turkey, Aug. 28-Sept. 4. Professor Dr. Ihsan Sükrü Aksel, Tunel Meydam, Beyoglu, Istanbul, Turkey, General Secretary.

International Gerontological Congress, London and Oxford, England, July 12-22, 1954. Prof. R. E. Tunbridge, General Infirmary, Department of Medicine, The University, Leeds, England, President.

International Leprosy Congress, Madrid, Spain, Oct. 3-10. Dr. Felix Contreras, Moreto 15, Madrid, Spain, Secretary.

International Neurological Congress, Lisbon, Portugal, Sept. 7-12. Prof. Almeida Lima, Avenida do Brazil 53, Lisbon, Portugal, Secretary-General.

International Office of Documentation of Military Medicine, Rome, Italy, Oct. 14-18. Colonel Medecin Prof. A. Campana, Office of the Ministero della Difesa-Esercito, Rome, Italy, Secretary.

International Physiological Congress, Montreal, Canada, Aug. 31-Sept. 4. Dr. A. S. V. Burgen, Dept. of Physiology, McGill University, Montreal, Canada, Secretary.

International Society for the Study of Biological Rhythms, Basle, Switzerland, Sept. 18-19. For information write: Prof. Dr. F. Georgi, Neurologische Universitats-Poliklinik, Socinstrasse 55, Basle, Switzerland.

Journees Medicales, Paris, France, April 21-25, 1954. For information write: Secretariat of the Journees, 12, rue Pierre-Geofroix, Colombes (Seine) France.

Latin American Congress of Obstetrics and Gynecology, *Buenos Aires,* Argentina, Oct. 26-31.

Latin American Congress of Otorhinolaryngology, Cáracas, Venezuela, Feb. 21-25, 1954. Dr. Victorino Marquez Reveron, Centro Medico, Caracas, Venezuela, Secretary-General.

Pacific Science Congress, Quezon City and Manila, Philippines, Nov. 16-28. Dr. Patrocinio Valenzuela, College of Pharmacy, University of the Philippines, Quezon City, Philippines, Secretary-General.

Pan American Congress of Otorhinolaryngology and Bronchoesophagology, Mexico, D.F., Mexico, Feb. 28-March 4, 1954.

Pan American Medical Association, International Medical Cruise Congress, S. S. Nieuw Amsterdam, Jan. 6-22, 1954. Dr. Joseph J. Eller, 745 Fifth Avenue, New York 22, N. Y., U. S. A., Executive Director.

Pan American Medical Women's Alliance, Beekman Towers Hotel, New York, N. Y., Sept. 24-Oct. 1. Dr. Ina Marsh, 140 Linwood Ave., Buffalo, N. Y., U. S. A., Registration Chairman.

Persian Gulf Medical Society, Dhahran, Saudi Arabia, Dec. 7-8. Dr. N. J. Conan Jr., Department of Internal Medicine, Arabian American Oil Company, Dhahran, Saudi Arabia, Secretary.

Regional Meeting, American College of Physicians, San Juan, Puerto Rico, Oct. 15-17. Dr. R. Rodriquez-Molina, Veterans Administration Center, San Juan, Puerto Rico, Governor.

Sectional Meeting, American College of Surgeons, London, England, May 17-19, 1954. Dr. Michael L. Mason, 40 East Erie St., Chicago 11, Ill., U. S. A., Secretary.

World Conference on Medical Education, British Medical Association House, Tavistock Square, W.C.1, London, England, Aug. 22-29. Secretariat: World Medical Association, 2 East 103d St., New York 29, N. Y., U. S. A.

World Congress of the World Confederation for Physical Therapy, London, England, Sept. 7-12. Miss M. J. Neilson, Chartered Society of Physiotherapy, Tavistock House, South, Tavistock Square, London, W.C.1, England, Secretary.

World Medical Association, The Hague, Netherlands, Aug. 31-Sept. 7. Dr. Louis H. Bauer, 345 East 46th St., New York 17, N. Y., Secretary-General.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 22-24, 1954. Sec., Dr. D. G. Gill, 537 Dexter Ave., Montgomery.

Alaska:* Anchorage and Juneau, Sept. 7. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

Arizona:* *Examination.* Phoenix, Oct. 22-23. *Endorsement.* Phoenix, Oct. 24. Executive Secretary, Mr. Robert Carpenter, 401 Security Bldg., Phoenix.

Arkansas:* *Examination.* Little Rock, Nov. 5-6. Sec., Dr. Joe Verser, Harrisburg.

Colorado:* *Reciprocity.* Denver, Oct. 13. Final date for filing application is Sept. 14. *Examination.* Denver, Dec. 15-16. Final date for filing application is Nov. 14. Executive Secretary, Miss Beulah H. Hudgens, 831 Republic Bldg., Denver 2.

Connecticut:* *Regular. Examination.* New Haven, Nov. 10-11. Reciprocity actions are taken continuously. Secretary to the Board, Dr. Creighton Barker, 160 St. Ronan St., New Haven. *Homeopathic.* Derby, Nov. 10-11. Sec., Dr. Donald A. Davis, 38 Elizabeth St., Derby.

Delaware: Dover, Jan. 12-14, 1954. Sec., Dr. Joseph S. McDaniel, 229 South State St., Dover.

District of Columbia:* *Reciprocity.* Washington, Sept. 14. Sec., Dr. Daniel L. Seckinger, 4130 E. Municipal Bldg., Washington.

Florida:* *Examination.* Jacksonville, Nov. 22-24. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami 36.

Guam: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Director of Medical Services, Guam Memorial Hospital, Agana.

Idaho: Boise, Jan. 11-13, 1954. Executive Secretary, Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Illinois: Chicago, Oct. 6-8. Superintendent of Registration, Mr. Fredric B. Selcke, *State House, Springfield.*

Iowa:* *Examination.* Des Moines, Dec. 7-9. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

Kansas: Topeka, Dec. 9-10. Sec., Dr. O. W. Davidson, 864 New Brotherhood Bldg., Kansas City.

Maine: Portland, Nov. 12-13. Sec., Dr. Adam P. Leighton, 192 State Street, Portland.

Maryland: *Examination.* Baltimore, Dec. 8-11. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore 1.

Michigan:* *Examination.* Lansing, Oct. 14-16. Sec., Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing 8.

Minnesota:* Minneapolis, Oct. 20-22. Sec., Dr. E. M. Jones, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: *Reciprocity.* Jackson, December. Assistant Secretary, Dr. R. Whitfield, Old Capitol, Jackson 113.

Montana: Helena, Oct 5. Sec., Dr. S. A. Cooney, 214 Power Block, Helena.

Nebraska:* *Examination.* Omaha, June 1954. Director, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

Nevada:* Reno, Oct. 6. Sec., Dr. George H. Ross, 112 Curry St., Carson City.

New Hampshire: Concord, Sept. 9. Sec., Dr. John S. Wheeler, 107 State House, Concord.

New Jersey: *Examination.* Trenton, Oct. 20-23. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

New Mexico:* Oct. 12-13, Santa Fe. Sec., R. C. Derbyshire, 227 E. Palace Ave., Sante Fe.

New York: *Examination.* New York, Syracuse, Buffalo and Albany, Oct. 6-9. Sec., Dr. Stiles D. Ezell, 23 South Pearl St., Albany.

North Carolina: *Reciprocity.* Asheville, Oct. 12. Sec., Dr. Joseph J. Combs, 716 Professional Bldg., Raleigh.

North Dakota: *Examination.* Grand Forks, Jan. 6-9, 1954. *Reciprocity.* Grand Forks, Jan. 9. Sec., Dr. C. J. Glaspel, Grafton.

Ohio: *Examination.* Columbus, December. *Reciprocity.* Columbus, Oct. 6. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

Oregon:* *Reciprocity.* Portland, Oct. 16-17. Sec., Dr. Wilmot C. Foster, 609 Failing Bldg., Portland 4.

Pennsylvania: *Examination.* Philadelphia, January 1954. Acting Secretary, Mrs. Margaret G. Steiner, Box 911, Harrisburg.

Rhode Island:* *Examination.* Providence, Oct. 1-2. Administrator of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Carolina: *Reciprocity.* Columbia, Sept. 21. Sec., Mr. N. B. Heyward, 1329 Blanding St., Columbia.

South Dakota:* *Examination.* Sioux Falls, Jan. 19-20, 1954. Reciprocity can be obtained at any time between meetings of board. Executive Secretary, Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Tennessee:* *Examination.* Memphis, Sept. 30-Oct. 1. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis.

Texas: Fort Worth, Nov. 12-14. Reciprocity applicants must be completed *30 days prior to the meeting date.* Sec., Dr. M. H. Crabb, *1714 Medical* Arts Bldg., Fort Worth 2.

West Virginia: Charleston, Oct. 19. Sec., Dr. N. H. Dyer, State Office Bldg., Charleston 5.

Wisconsin:* *Reciprocity.* Madison, October. *Examination and Reciprocity.* Madison, Jan. 12-14, 1954. Sec., Dr. A. G. Koehler, 46 Washington Blvd., Oshkosh.

Wyoming: Cheyenne, Oct. 5. Sec., Dr. Franklin D. Yoder, State Office Bldg., Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: On application. Juneau or other towns in Territory as decided by Board. *Reciprocity.* On application. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

Arizona: *Examination.* Tucson, Sept. 15. Sec., Mr. Herbert D. Rhodes, University of Arizona, Tucson.

Arkansas: *Examination.* Little Rock, Oct. 6-7. Sec., Mr. Louis E. Gebauer, 1002 Donaghey Bldg., Little Rock.

Colorado: *Examination.* Denver, Sept. 9-10. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 18.

Connecticut: New Haven, Oct. 10. Address: State Board of Healing Arts, 52 Whitney Ave., New Haven 10.

District of Columbia: *Examination.* Washington, Oct. 19-20. Sec., Dr Daniel L. Seckinger, 4130 E. Municipal Bldg., Washington.

Florida: *Examination.* Gainesville, Nov. 7. Sec., Mr. M. W. Emmel, Box 340, University of Florida, Gainesville.

Minnesota: *Examination.* Minneapolis, Oct. 6-7. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis 14.

Nebraska: *Examination.* Omaha, Oct. 6-7. Director, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

Nevada: *Examination.* Reno, Oct. 6. Sec., Dr. Donald G. Cooney, Box 9005, University Station, Reno.

New Mexico: *Examination.* Santa Fe, Oct. 18. Sec., Mrs. Marguerite Cantrell, Box 1592, Santa Fe.

Oklahoma: *Examination.* Oklahoma City, August 28-29. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: Portland, Aug. 29. Final date for filing application is Aug. 12. Portland, Dec. 5. Sec., Dr. Charles D. Byrne, University of Oregon, Eugene.

South Dakota: *Examination.* Vermillion, Dec. 4-5. Sec., Dr. Gregg M. Evans, 310 E. 15th St., Yankton.

Tennessee: *Examination.* Memphis, Sept. 23-24. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis 3.

Texas: *Examination.* Dallas and Galveston, October. Sec., Bro. Raphael Wilson, 407 Perry-Brooks Bldg., Austin.

Wisconsin: *Examination.* Madison, Sept. 19. Final date for filing application is Sept. 11. Milwaukee, Dec. 5. Final date for filing application is Nov. 27. Sec., Dr. W. H. Barber, 621 Ransom St., Ripon.

---

* Basic Science Certificate required.

DEATHS

Gilbert, Newell Clark ⊕ Chicago; born in Clinton, Ill., Dec. 5, 1880; Northwestern University Medical School, Chicago, 1907; professor of medicine emeritus at his alma mater, where he was past chairman of the department of internal medicine; served during World War I; later a lieutenant colonel in the medical officers reserve corps; specialist certified by the American Board of Internal Medicine; past president of the Chicago Heart Association; member of the Central Society for Clinical Research, Association of American Physicians, Chicago Society of Internal Medicine, Institute of Medicine of Chicago, and the American Society for Clinical Investigations; fellow of the American College of Physicians; vice-chairman, 1935-1936 and chairman 1936-1937, Section on Pharmacology and Therapeutics, American Medical Association, where he was chairman of the Section on Practice of Medicine, 1938-1939; senior attending physician, St. Luke's Hospital; formerly chief editor of the *Archives of Internal Medicine*; died in St. Joseph's Hospital in Milwaukee Aug. 1, aged 72, of bile peritonitis following an operation for acute cholecystitis and gallstones.

Crawford, Robert Hope ⊕ Rutherfordton, N. C.; born in Rock Hill, S. C., in 1890; Johns Hopkins University School of Medicine, Baltimore, 1914; member of the founders group of the American Board of Surgery; member of the Southern Surgical Association and the Southeastern Surgical Congress; fellow of the American College of Surgeons; served overseas during World War I, and in 1919 received from King Alexander of Greece the Medal of Military Merit, awarded him for distinguished service in Greece with the American Red Cross in helping to stamp out a typhus epidemic in Macedonia; medical director of the Rutherford Hospital; died April 15, aged 63, of squamous cell carcinoma of the chest wall.

Calcote, Royal Jackson ⊕ Little Rock, Ark.; born in Ruston, La., Sept. 11, 1893; University of Arkansas School of Medicine, Little Rock, 1918; clinical professor of surgery (ophthalmology) at his alma mater; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology; formerly treasurer of the Arkansas Medical Society, and secretary of the Pulaski County Society; served during World Wars I and II; consultant, Arkansas School for the Blind; affiliated with St. Vincent Infirmary and Arkansas Baptist and Missouri Pacific hospitals; died in Hot Springs, Ark., June 28, aged 59, of cerebral hemorrhage.

Ennett, Nathaniel Thomas ⊕ Beaufort, N. C.; born Jan. 5, 1877; Medical College of Virginia, Richmond, 1907; formerly on the faculty of his alma mater; specialist certified by the American Board of Preventive Medicine and Public Health; health officer of Carteret County; for many years health officer of Pitt County; formerly health officer of Surry County; past president of the North Carolina Public Health Association and the Second District Medical Society; at one time practiced in Richmond, Va., where he was medical director for the city board of education from 1911 to 1932 except for one year; died in Morehead City (N. C.) Hospital June 23, aged 76, of cerebral hemorrhage.

Echtman, Joseph ⊕ New York City; born in Russia, Jan. 15, 1886; New York Homeopathic Medical College and Flower Hospital, 1919; served on the faculty of New York Medical College, Flower and Fifth Avenue Hospitals; formerly affiliated with Mount Sinai Hospital and the cardiac clinic of Beth Israel Hospital; chief of physiotherapy clinic, Stuyvesant Polyclinic, from 1936 to 1942 and later director of postgraduate courses in physical medicine in this institution; for many years chief of physical medicine at Beth David Hospital; author of "The Cure of Rheumatoid Arthritis and Related Conditions by Physical Medicine," published in 1951; died June 27, aged 67, of carcinoma.

Braunstein, William Peter ⊕ Weehawken, N. J.; born in Union, N. J., Jan. 21, 1900; Columbia University College of Physicians and Surgeons, New York, 1923; specialist certified by the American Board of Pathology; member of the College of American Pathologists and the American Society of Clinical Pathologists; for many years assistant medical examiner in Hudson County; attending pathologist at North Hudson Hospital in Weehawken and president of the staff of St. Mary's Hospital, in Hoboken, where he was director of pathology; died in Lenox Hill Hospital, New York, June 23, aged 53, of carcinoma of the lung.

Anderson, Marion Ellsworth, Clinton, Iowa; Northwestern University Medical School, Chicago, 1911; served during World War I; died in the Jane Lamb Hospital June 15, aged 70, of carcinoma of the urinary bladder.

Bartolucci, Raymond John ⊕ Albuquerque, N. Mex.; Chicago Medical School, 1935; member of the American Academy of General Practice; died July 6, aged 45.

Bloom, Harold Abel ⊕ New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1918; died April 24, aged 59, of coronary occlusion.

Bowen, Frederick Stuber ⊕ Woodburn, Iowa; Rush Medical College, Chicago, 1901; served during World War I; died in the Veterans Administration Hospital, Des Moines, June 3, aged 78, of arteriosclerotic heart disease.

Boyd, Leon Morelle ⊕ Alexandria, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1908; died in Our Lady of Mercy Hospital May 29, aged 69, of a heart attack.

Briggs, Carl F. ⊕ Sullivan, Ind.; Rush Medical College, Chicago, 1902; served as secretary and president of the Sullivan County Medical Society; surgeon for the Chicago and Eastern Illinois Railroad; died June 20, aged 72, of coronary disease.

Briggs, Robert Truman, Hempstead, N. Y.; Long Island College Hospital, Brooklyn, 1898; served during World War I; died June 28, aged 79, of a heart attack.

Brown, Joseph C., Lookout, W. Va.; Baltimore Medical College, 1895; served as a member of the staffs of Weston (W. Va.) State Hospital and the Spencer (W. Va.) State Hospital; died July 13, aged 81, of arteriosclerosis.

Bullen, Victor Emmanuel ⊕ Paterson, N. J.; New York University Medical College, New York, 1896; died in Paramus, June 29, aged 84.

Burst, Emil Andrew ⊕ St. Louis; St. Louis University School of Medicine, 1909; served during World War I; on the staff of the Lutheran Hospital, where he died June 20, aged 68, of ruptured abdominal aortic aneurysm.

Butterfield, Edwin Jay ⊕ Tucson, Ariz.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; member of the Iowa State Medical Society; died May 13, aged 73, of carcinoma of the stomach.

Chasatzky, Isaac Samuel ⊕ New York City; University of Kharkov Faculty of Medicine, Russia, 1913; affiliated with Mount Sinai Hospital; died recently, aged 64, of tuberculosis of the kidneys.

Clark, Ernest Walton Jr. ⊕ Haddon Heights, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1922; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; served on the staffs of Cooper Hospital in Camden and Wills Hospital in Philadelphia; died in Friends Hospital, Philadelphia, April 24, aged 56.

⊕ Indicates Member of the American Medical Association.

Cohen, Franklin Harry, Norfolk, Va.; University of Virginia Department of Medicine, Charlottesville, 1934; member of the American Academy of General Practice; served during World War II; affiliated with De Paul Hospital and the Norfolk General Hospital, where he died June 12, aged 43, of cerebral hemorrhage and hypertension.

Cooper, Fay Maxey ⊕ Oklahoma City; University of Arkansas School of Medicine, Little Rock, 1925; clinical professor of ophthalmology at University of Oklahoma School of Medicine; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology; past president of the Oklahoma City Clinical Society; affiliated with St. Anthony, University, and Wesley hospitals; died June 16, aged 53, of myocardial infarction.

Cowart, Newit Walter, Wiggins, Miss.; Memphis (Tenn.) Hospital Medical College, 1908; died May 19, aged 74.

Crecelius, Harry Alfred ⊕ Plains, Mont.; Beaumont Hospital Medical College, St. Louis, 1897; served as county physician and health officer; died June 2, aged 77.

Crosbie, George Torance, Belle Vernon, Pa.; Starling Medical College, Columbus, 1898; on the staff of the Charleroi Monessen Hospital in Charleroi, where he died June 21, aged 77, of carcinoma of the bladder.

Crosland, Edward Samuel ⊕ Royersford, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1922; died in Memorial Hospital, Pottstown, April 21, aged 56, of acute cardiac dilatation.

Dana, Lawrence Wellington ⊕ Kane, Pa.; Jefferson Medical College of Philadelphia, 1903; died in Hamot Hospital, Erie, April 24, aged 73, of cardiac failure.

Denyes, Gerald Foster ⊕ Toledo, Ohio; Queen's University Faculty of Medicine, Kingston, Ontario, Canada, 1916; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; served with the Canadian Army during World War I; formerly affiliated with Toledo, Mercy, and Flower hospitals; died in Good Samaritan Hospital in West Palm Beach, Fla., June 22, aged 57, of coronary thrombosis.

DeWitt, Charles Cornelius, Louisville, Ky.; University of Louisville Medical Department, 1917; served during World War I; died in Norton Memorial Infirmary April 19, aged 76, of bleeding duodenal ulcer, hemiplegia, and cerebral thrombosis.

Duckwall, Francis A., Dayton, Ohio; Medical College of Ohio, Cincinnati, 1877; died June 24, aged 101, of cerebral hemorrhage.

Dudley, Alberta Pasch Webb ⊕ Oklahoma City, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1942; instructor in medicine at her alma mater; assistant medical director of the Oklahoma Defense Blood Center; died in St. Anthony's Hospital June 1, aged 53, of carcinoma.

Duncan, Henry, Marietta, Minn.; Rush Medical College, Chicago, 1900; died May 22, aged 85.

Eagan, Edward Francis ⊕ Lynn, Mass.; Yale University School of Medicine, New Haven, Conn., 1930; certified by the National Board of Medical Examiners; specialist certified by the American Board of Otolaryngology; served during World War II; twice elected to the school committee of Lynn; affiliated with Lynn and Union hospitals in Lynn, and the Carney Hospital in Boston; died in Cape Cod Hospital in Hyannis June 13, aged 47, of coronary occlusion and myocardial infarction.

Edson, Elmer Rockwood ⊕ Portland, Ore.; University of Pennsylvania Department of Medicine, Philadelphia, 1897; served overseas as a medical officer for the Canadian and U. S. Army during World War I; associated with the Veterans Administration Hospital and Veterans Administration regional services from 1923 to 1948; died in Lyons, N. Y., May 31, aged 80, of coronary thrombosis.

Ertzman, Richard Leonard ⊕ Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1903; served during World War I; died June 18, aged 73, of coronary occlusion.

Farquhar, David Clifford ⊕ Monessen, Pa.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; served during World War I; affiliated with Charleroi-Monessen Hospital in Charleroi; died July 2, aged 71, of a heart attack.

Feman, Jacob George ⊕ Keansburg, N. J.; University of Maryland School of Medicine, Baltimore, 1930; on the staffs of the Monmouth Memorial Hospital in Long Branch and the Riverview Hospital in Red Bank; died in Memorial Hospital, New York City, June 9, aged 48, of carcinoma of the colon.

Levy, Walter Edmond Jr., New Orleans; born in New Orleans April 1, 1922; Tulane University of Louisiana School of Medicine, New Orleans, 1945; interned at Touro Infirmary; served a residency in obstetrics and gynecology at Charity Hospital; served during World War II; clinical instructor in obstetrics and gynecology at Louisiana State University School of Medicine; affiliated with Touro Infirmary; consulting obstetrician at Flint Goodridge Hospital; on the courtesy staff of the Sara Mayo Hospital; died June 27, aged 31.

Marthens, Jesse Grant, Dayton, Ohio; Syracuse University College of Medicine, 1907; served during World War I; died June 18, aged 69.

Miller, James Wesley ⊕ Philadelphia; Jefferson Medical College of Philadelphia, 1923; affiliated with Thomas M. Fitzgerald-Mercy Hospital in Darby and the Presbyterian, St. Vincent's, and St. Agnes hospitals; died in Bryn Mawr (Pa.) Hospital June 24, aged 59, of coronary thrombosis with acute myocardial infarction.

Moore, Harold H. ⊕ Ottumwa, Iowa; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1912; fellow of the American College of Surgeons; affiliated with Ottumwa Hospital and St. Joseph's Hospital, where he died April 20, aged 63, of pulmonary thrombosis, myocardial infarction, and arteriosclerotic heart disease.

Murrow, Joseph S, ⊕ Apalachicola, Fla.; University of Georgia Medical Department, Augusta, 1899; formerly associated with the U. S. Public Health Service; died in the Franklin County Hospital May 28, aged 80, of hypostatic pneumonia.

Nelson, Elford John ⊕ Pomona, Calif.; University of Toronto Faculty of Medicine, Toronto, Canada, 1920; died suddenly, June 10, aged 56, of acute coronary thrombosis, chronic arthritis, and arteriosclerosis.

O'Keeffe, James Vincent ⊕ Lynn, Mass.; Harvard Medical School, Boston, 1909; affiliated with Lynn Hospital; died June 12, aged 70, of coronary thrombosis.

Payne, John Edward Jr., Reidsville, N. C.; Meharry Medical College, Nashville, Tenn., 1942; interned at City Hospital, Winston-Salem; served during World War II; died April 10, aged 37, of a heart attack.

Pentecost, Milton Irving ⊕ Freeport, Maine; Jefferson Medical College of Philadelphia, 1908; member of the Medical Society of the State of Pennsylvania; served overseas during World War I; for many years on the staff of the Scranton (Pa.) State Hospital; died May 23, aged 70, of a heart attack.

Phillips, Clyde Lincoln ⊕ Hilo, Hawaii; Northwestern University Medical School, Chicago, 1929; died May 26, aged 53.

Plath, John Henry, Wyckoff, N. J.; University and Bellevue Hospital Medical College, New York, 1899; died June 21, aged 76, of encephalopathy due to cerebral arteriosclerosis.

Powell, John Franklin, Greentown, Ind.; Medical College of Indiana, Indianapolis, 1897; died June 5, aged 78, of heart disease.

Pracht, Henry Walters ⊕ Miami Beach, Fla.; University of Pittsburgh School of Medicine, 1928; died May 13, aged 49, of myocardial infarction and coronary occlusion.

Snow, Glenadine Calkins, Ypsilanti, Mich.; University of Michigan Medical School, Ann Arbor, 1921; died in St. Joseph Mercy Hospital, Ann Arbor, May 10, aged 64, of coronary thrombosis and arteriosclerosis.

GOVERNMENT SERVICES

NAVY

Sea Duty for WAVES.—The Navy announced July 29 that it will call for volunteers from the enlisted women of the hospital corps to fill 63 billets on ships of the Military Sea Transportation Service. This is the first time that military billets aboard ships have been opened to enlisted WAVES. Twenty-four Navy nurses will thus be replaced by the enlisted hospital corps WAVES, and the nurses will then be available for assignment to Navy hospitals ashore. A minimum of two enlisted women will be assigned to each ship, and they will be assigned only to ships that have a Navy nurse aboard. The tour of duty aboard these ships is 21 months. Of the billets available, 28 are in the Atlantic and 35 in the Pacific.

Motor Vehicle Accidents.—The Navy's Bureau of Medicine and Surgery has completed tabulation of motor vehicle accidents in which Navy and Marine Corps personnel were involved during the year 1951. The 7,940 new admissions to the Navy's sick list as a result of motor vehicle accidents accounted for one of every four new admissions for accidental injuries during the year. Each of these new admissions accumulated an average of 42.2 days on the sick list and a total manpower loss of 335,279 sick days.

These accidents caused 603 deaths during the year, of members of the Navy and Marine Corps. This was the second highest death rate due to motor vehicle accidents in recorded naval history. Almost three-fourths of the total admissions resulted from accidents involving passenger automobiles. The statistics reveal that the highest rate occurred among personnel under 30 years of age.

PUBLIC HEALTH SERVICE

Evaluation of Gamma Globulin.—A nation-wide cooperative research effort to evaluate the use of gamma globulin against poliomyelitis has been sponsored by the Public Health Service in collaboration with the Association of State and Territorial Health Officers, the American Physical Therapy Association, and the D. T. Watson School of Physiatrics, which is affiliated with the University of Pittsburgh School of Medicine. An advisory committee comprised of 17 leading poliomyelitis authorities planned the investigation and will review its progress. The service's Communicable Disease Center at Atlanta, Ga., will coordinate the program.

Gamma globulin is being made available by the American Red Cross from the blood it collects and by the National Foundation for Infantile Paralysis from other, purchased stocks. The national supply of gamma globulin is being distributed by the Public Health Service, under a policy set by the Office of Defense Mobilization, to the state health officers, who are then responsible for its use in their own areas.

In Atlanta, a temporary organization, the National Gamma Globulin Evaluation Center, has been established within the Communicable Disease Center. Dr. Abraham M. Lilienfeld, assistant professor of epidemiology in the Johns Hopkins School of Hygiene and Public Health and a consultant to the Communicable Disease Center, is serving as director of the Evaluation Center. The National Gamma Globulin Evaluation Center neither distributes nor administers gamma globulin but is concerned solely with evaluation of its effects. It will be impossible to study all the expected multiple case households in all states, but an attempt will be made to survey as large a proportion as possible. Each patient in the study will be examined from 50 to 70 days after the beginning of illness by a trained physical therapist. These services are being arranged by the American Physical Therapy Association, aided by a grant from the National Foundation for Infantile Paralysis.

Venereal Disease Course.—The 21st venereal disease postgraduate course will be held at Chapel Hill, North Carolina, from Sept. 28 through Oct. 2 under the cosponsorship of the U. S. Public Health Service and the North Carolina University Schools of Medicine and of Public Health. For many years the courses in venereal disease were held twice annually at the U. S. Public Health Service Medical Center, Hot Springs National Park, Hot Springs, Ark., until the center was closed last June. The postgraduate course in venereal disease is open to all physicians. Applications for enrollment in the course starting on Sept. 28 should be sent to Dr. Harold Magnuson, director, Venereal Disease Experimental Laboratory, Box 687, Chapel Hill, N. C.

Laboratory Courses.—Agenda for two training courses, in fluoride analysis and the membrane filter in bacteriological analysis of water, and a seminar on individual household sewage disposal systems have been announced by the Environmental Health Center, Public Health Service. The course in fluoride analysis, to be given Sept. 17-18, includes discussion of the public health aspects of the fluoridation program, choice of compound and feeding equipment, and problems in fluoride determinations. Laboratory work will show visual and instrumental methods of determining fluoride in the presence of common interfering materials. The household sewage disposal system seminar, which will be given Sept. 23-25, will cover the role of individual household sewage systems in the field of sewage disposal, the development of household sewage disposal systems, and various types of sewage disposal systems. The second training course, on the membrane filter in bacteriological analysis of water, will be held Oct. 13-16. In addition to discussions of the physical and chemical properties of the membrane filter and filtration technique and procedures, laboratory work will be given on filtration of samples and incubation of membranes on enrichment medium. Letters of application for these courses should be sent to the Officer in Charge, Environmental Health Center, Public Health Service, 1014 Broadway, Cincinnati 2, Ohio, or to the Public Health Service Regional Offices.

VETERANS ADMINISTRATION

GI Insurance.—Some 4 million veterans with GI term insurance in force will no longer have to apply to the Veterans Administration for renewal of the policies for another five year term before their old policies expire. The VA will do this for them automatically, if their old policies are not lapsed at the expiration of the term period. This means the policy must be in force at the end of the term period, with the final premium having been paid on time. The new procedure went into effect July 23, 1953, when the President signed Public Law 148. The new law covers only those term policies that expire on or after July 23, 1953.

Personal.—Harvey V. Higley became Administrator of Veterans Affairs on July 22, 1953. He left the position of chairman of the board of the Ansul Chemical Company, Marinette, Wis., with which he has been associated since 1919.

FOREIGN LETTERS

DENMARK

Danish BCG Studies.—*Ugeskrift for Laeger* for June 25, 1953, contains 9 original articles and an editorial on BCG. The first of these articles is by Dr. Tage V. Hyge whose report several years ago of an outbreak of tuberculosis in a Danish school for girls between the ages of 12 and 18 has been held as a model of research, since even the most particular statistician could not find fault with the evidence in favor of BCG. The girls in this school were classified in three groups: (1) tuberculin-negative and not vaccinated with BCG, (2) tuberculin-negative and vaccinated with BCG, and (3) tuberculin-positive from the outset and not vaccinated with BCG. The tuberculosis morbidity was many times greater in the first than in the second group. The figures for all three groups are brought up-to-date by Hyge in the present article. Another original article, by Dr. E. Groth-Petersen, describes the inaccuracy with which laymen are apt to answer the question: "Have you been vaccinated with BCG?" Among 31,000 persons examined during a mass BCG vaccination campaign, the statements could be checked by records at a tuberculosis dispensary. It was found that 4.1% of those who said they had been vaccinated with BCG had in reality not been so vaccinated, while 9.1% who denied previous vaccination had in fact been vaccinated with BCG. Groth-Petersen suggests that these findings should be borne in mind when doubts arise over the efficacy of BCG in persons in whom tuberculosis develops after they think they have been vaccinated with BCG.

Several of the other original articles are concerned with complications of BCG vaccination. Evidently subcutaneous local abscesses often reflect defective vaccination technique, although even well-trained and careful vaccinators occasionally find that an intracutaneous injection of BCG is followed by a local abscess. During the last 3 years alone some 220,000 Danish children under school age have been vaccinated with BCG; a number three times greater than the total for the preceding 15 years. It is, therefore, not surprising, with this expansion of the campaign for BCG vaccination, that there would be several mishaps that alarm the public. It is pointed out in the editorial that, while the deaths from tuberculosis in Denmark have fallen to between only 400 and 500 yearly, some 2,500 new cases of tuberculosis are still being found yearly. There are also some 15,000 tuberculosis patients alive. In other words, though the tuberculosis mortality is low, the tuberculosis morbidity remains comparatively high, indicating the necessity for sustained BCG vaccination of the whole population.

Hypospadias.—Dr. Hans R. Sørensen's study of hypospadias was recently published as a doctorate thesis by Ejnar Munksgaard of Copenhagen. Hypospadias is classified in this study according to whether it was near the gland, penile-penoscrotal, or perineoscrotal. About three-quarters of the cases were in the first category, about one-eighth in the second, and about one-eighth in the third. Ninety cases of hypospadias were found among 27,613 male infants about 10 days old. Testicle retention was more frequent among the hypospadias patients than among other boys. The marriage rate of 77 patients over the age of 20 was the same as that of normal controls, and there was no essential difference between the two with regard to sex activities provided certain disabilities had been removed by operative treatment. A comparison with normal controls suggested that the fertility of 47 married patients was unimpaired in those with abnormality near the gland. This may also have been true for other cases, but for the more serious cases fertility was reduced but not extinguished. Sørensen believes that hypospadias is hereditary. Scrutiny of 90 maternity records and data obtained from 34 mothers failed to indicate fetal infections, malnutrition, somatic or psychic trauma, intoxications, or hemorrhages during pregnancy as factors of etiological importance. He finds no reason for advocating restrictive marriage measures on the hereditary factor in hypospadias or for recommending birth control for this reason.

At a recent meeting of the Danish Surgical Society, Dr. P. Fogh-Andersen calculated that every year in Denmark there are some 30 new patients with hypospadias requiring operation. He gave an account of 34 patients operated on at the surgical department C of the Rigshospital in Copenhagen according to the Denis-Browne technique. This plastic operation on the urethra has been shown on a follow-up examination more than a year later to have been eminently successful and without any tendency to stricture of the urethra. Indeed, this technique should henceforth be the standard operation for all the forms of hypospadias including the most serious. Another speaker on this occasion referred to 70 adult patients, 47 of whom had married. Their fertility was actually greater than that of controls without hypospadias, and, as there was no difference in fertility of the patients who had or had not been operated on, there is no need to operate on minor cases to promote fertility.

Future of Intended Suicides.—Since October, 1949, cases of poisoning by narcotics in Copenhagen have been centralized in the psychiatric department of the Bispebjerg Hospital. In 1951, this hospital dealt with 846 such patients out of a total of 1,276 registered for greater Copenhagen. In this year, the mortality for these cases in greater Copenhagen was 1.6%, whereas for the whole of Denmark it was about 25% in 1945. To answer the question, "What is the future of the patients recovering in the hospital from poisoning by narcotics?" Dr. Harald Hove has undertaken a follow-up study of the first 500 patients whose attempts to commit suicide were thwarted in the Bispebjerg Hospital and whose fate two to three years later was investigated. Only six of these patients could not be traced. Of the 30 who had died since discharge from hospital, 6 had died a natural death (tuberculosis, heart disease, and other causes). The remaining 24 had been successful in committing suicide. Most of the 500 had attempted to commit suicide under emotional stress, in association with drunkenness in 74. Only 21 of the 500 could be classed as insane, but there were as many as 29 who suffered from constitutional psychopathia, 9 from "intellectual inferiority," 48 from chronic alcoholism, 11 from narcomania, 12 from epilepsy, and 3 from organic encephalopathy. In several cases, more than one of the above conditions occurred in the same patient. Altogether about 25% of the 500 were handicapped by conditions that hamper adaptation to the requirements of life in a modern community. It was in this group that most of the cases of recurrent attempts to commit suicide were found.

Among the 72 patients who were readmitted to the hospital for attempted suicide or who were found dead as the result of suicide, there were only 2 who attempted to commit suicide again within a month of the first attempt. All the successful suicides occurred over the observation period of two to three years. Among the patients readmitted to the hospital for attempted suicide during this observation period, there were several who were readmitted several times (three to five times). Dr. Hove concludes that probably not more than 20% of the 500 patients attempted suicide again during the period under review and that the staff of his hospital can be cheered by the reflection that most of the patients over whom they toil may be expected to recover not only momentarily but for a long time to come. Dr. Hove's findings are published in full in *Ugeskrift for Laeger* for April 23, 1953.

The items in these letters are contributed by regular correspondents in the various foreign countries.

LONDON

Vegetable Juices.—In a recent issue of the *Monthly Bulletin of the Ministry of Health and the Public Health Laboratory Service* (**12**:78 [April] 1953) H. E. Magee published an analysis of some of the better known constituents of vegetable juices. These are summarized in the following table, in which the figures in parentheses represent the content of the vegetable (as opposed to the juice):

Juice	Total Sugars (as Glucose) Grams per 100 Ml. (Gm.)	Iron, Mg. per 100 Ml. (Gm.)	Calcium, Mg. per 100 Ml. (Gm.)	Vitamin B_1, Mg. per 100 Ml. (Gm.)
Broccoli leaves.....	3.00 (0.4)	0.60 (1.52)	18.70 (160)	15.0
Cabbage..........	4.17 (8.3)	1.02 (1.0)	16.90 (65)	75.0 (75)
Carrots...........	7.11 (5.4)	0.30 (0.6)	0.49 (48)	30.0 (60)
Celery.............	2.08 (1.2)	0.43 (0.6)	0.62 (52)	15.0 (30)
Kale...............	3.71	1.60 (2.5)	11.60 (200)	15.0 (120)
Melon.............	4.33	0.42	0.40	30.0
Parsley...........	0.44 (8.8)	1.12 (8.0)	6.30 (325)	30.0 (120)
Spinach...........	1.85 (1.2)	1.02 (4.0)	0.75 (595)	Nil (100)
Tomato...........	3.06 (2.8)	0.08 (0.4)	4.05 (13)	15.0 (60)
Watercress........	*0.20 (0.6)*	*2.12 (1.6)*	*2.90 (222)*	*30.0 (120)*

In the case of vitamin C, only kale juice was found to have any appreciable amount, 46 mg. per 100 ml.; this was probably due to the absence of oxidases or that of antioxidases. Investigations showed that the vitamin C in many vegetable juices was quite unstable. The reaction of all the juices examined was very close to neutrality, and it was found that they practically all had a high buffering capacity. When milk, which is well known for its buffering capacity, was used as the standard, spinach juice was found to surpass it, while the juices of cabbage, kale, and parsley were not far behind. The comment is made that "the high buffering capacity of the juices suggests that they might be valuable in the treatment of hyperchlorhydria." It is noted that the reaction of the fresh juices, and their buffering capacities, would favor bacterial growth at suitable temperatures; "perhaps the most to be feared is B. botulinus." Juices can be preserved in three ways: "(1) by ensuring scrupulous cleanliness of the vegetables and then keeping the juice at refrigerator temperature from the time of expression until consumption, (2) by pressure sterilization, and (3) by lowering the pH to 4.2 or less, followed by low temperature pasteurisation." Attention is also drawn to the significant amounts of minerals in vegetable juices and to recent work indicating that some green vegetables, and their juices, contain appreciable amounts of some of the essential amino acids.

On the relative merits of juices as compared with whole vegetables, the view is expressed that "for the healthy person then, vegetable juices can hardly be regarded as a substitute for whole vegetables and their place in the normal diet would seem to be merely as an appetiser or cocktail." On their therapeutic value the position is summed up as follows: "Claims are made that various juices in amounts up to 500 ml. daily are beneficial in hyper-tension, certain types of cardiovascular and kidney disease and in obesity, but it is not clear to what extent other elements in the therapy employed, e. g., low calorie diets and low sodium chloride, were contributory factors. Good effects have also been ascribed to the juices in rheumatic, degenerative and toxic states, and they are probably attributable to their all-around protective action. The evidence indicates that good results are to be expected fr large amounts of juices (up to 1 litre daily) in the treatm of peptic ulceration. But they have also given good result the treatment of diarrhoea, colitis and toxaemia of ga intestinal origin."

Antibiotic Production in the United Kingdom.—It has been reported that the output of penicillin in this country April constituted an all-time record: the average weekly ou was 2,136,600 megaunits. This compares with 1,296,000 m units in 1952 and 723,700 megaunits in 1951. For the four months of the year exports of penicillin salts and pre tions amounted to 17,500,000 megaunits, compared with over 12 million megaunits in the same period last year. February, 1953, the price was further cut by 3s.9d. to 21s. per 5 megaunits. In reporting these figures, the *Fina* *Times* also announces an interesting development in the antibiotic field, whereby a British company "has made an arrangement with an American company to make the crude broth from which aureomycin is extracted," and it is expected that a substantial output will be reached by September. According to the same course, "this will make the United Kingdom independent of the imported crude which is now coming from the United States. . . . The implications . . . are many. It could mean that aureomycin will be available to doctors on the same basis as penicillin when it becomes wholly made in England. At present these drugs [i. e., aureomycin and oxytetracycline] can only be used by hospitals and doctors in special cases."

Ambulance Service Costs.—Figures just issued for the year ended March 31, 1952, show that the Ambulance Service cost the country £8,608,828 during this year. An analysis of this figure shows that 56.4% was spent on the operational staff, 20.3% on the fueling and maintenance of vehicles, 6% on provision of vehicles, 2.8% on maintenance of such things as buildings and furniture, 1.2% on provision of land and buildings, and 13.3% on other expenditures, including administrative expenses. During the year the service conveyed 11 million patients, and the mileage covered was 92 million miles. This compares with 9 million patients and 89 million miles in the previous year. The average cost per patient fell from 15s.6d. to 15s.2d., and the average number of miles run per patient fell from 9 to 8.3. The number of ambulances and cars in use was 4,411. In addition a large number of private cars were available on a voluntary basis through the Hospital Car Service, and 15,000 patients traveled by rail under arrangements made by local health authorities.

The Nation's Drug Bill.—The serious view that the government takes of the rising drug bill is well demonstrated by the fact that Mr. Lan Macleod, the Minister of Health, attended in person the Annual Conference of Local Committees of the British Medical Association in order to appeal for the support of the medical profession in his efforts to reduce this unruly item without disciplinary action. He described the rising cost of the drug bill as one of the gravest and most urgent problems that confronted the National Health Service. He said that the exchequer could not go on paying an annual bill of something like 40 million pounds for drugs prescribed by general practitioners (when the whole range of dressings and appliances prescribed is considered, the figure is nearer 60 million pounds) unless the drugs were all essential for the proper treatment of patients.

He advanced two major reasons for the increase in the drug bill from £31,500,000 in 1949-1950 to an estimated figure of £46,500,000 in 1953-1954: (1) an increase in the total number of prescriptions dispensed, over 200 million a year (*the latest figures just announced are those for August,* 1952: 12,953,542 at a total cost of £2,709,428, or an average of 50.2d. per prescription), and (2) an increase in the average cost of prescriptions from 2s.9d. in 1948-1949 to an estimated 4s.3d. in 1953-1954, due to (*a*) the introduction of new valuable but c [illegible] drugs, (*b*) [illegible] rise in the ingredient prices until this [illegible] though some [illegible] gs, e. g., some of the antibiotics, w [illegible] derably ch [illegible] and (c) the prescribing of an increa [illegible] ion of [illegible] ry preparations (in 1952, proprieta [illegible] total number of prescriptions, [illegible] cost, and 44.5% of their total [illegible]

He quot [illegible] nd prescribing
propri [illegible] rd), prepara-
was [illegible] ary
standard
in
for
of

around £50,000 could be saved if comparable standard preparations were used instead of proprietary preparations in the treatment of peptic ulcer and heart disease.

The minister then proceeded to indicate that practical ways in which practitioners could assist him in reducing this expenditure on drugs. 1. They could make more careful use of "National Formulary" preparations by referring to the two tables of proprietary preparations in the "Formulary" (those for which an identical preparation is available in the "Formulary" and those for which there is a "Formulary" preparation substantially the same or reputed to have an analogous therapeutic effect) and always prescribe a "Formulary" preparation unless there was a special reason to do otherwise. Incidentally, the Minister pointed out, the "Formulary" preparations were recommended by experts of the medical and pharmaceutical professions (quite independently of the Ministry of Health), and there was no reason to regard them as inferior simply because they were cheaper. 2. Practitioners could satisfy themselves before prescribing a proprietary preparation not included in the two "Formulary" lists that there were adequate grounds for accepting its therapeutic value in treating the particular condition for which it was prescribed. 3. Practitioners could resist pressure from patients to prescribe particular preparations that had been recommended or that they had read about in technical or semitechnical journals. 4. Practitioners could also refrain from prescribing unreasonably large quantities of a drug or dressing.

The steps being taken by the Ministry included the issuing of a price list of "Formulary" preparations and proprietary preparations listed in the "Formulary" or occupying a high place on the basis of frequency of prescribing. Physicians would thus be made fully aware of the cost of what they were prescribing. In addition, there would shortly be published the Cohen committee's classification of proprietary preparations. This would enable physicians to be told the names of preparations in the two "doubtful" categories covering drugs that were not of proved therapeutic value and might not be prescribed. Simultaneously the Ministry was proceeding, in consultation with the manufacturers, to investigate the production costs of selected proprietary preparations in the categories that the Cohen committee considered prescribable subject to satisfactory price arrangements.

While the problem may be a relatively simple one from the point of view of the Minister of Health, the implications, if he succeeds in his economy drive, are far from simple. One of the most serious implications is the effect on the research budgets of the leading pharmaceutical houses. The Minister has consistently paid tribute to the considerable amount of research done by these companies, but he has tended to take the line that his major interest is the drug bill and that research and, incidentally, export sales are not his responsibility. That the pharmaceutical companies are becoming worried about the future of their research departments is well brought out in the recently published annual report of the chairman of the company owing the largest chain of retail pharmacies in the United Kingdom. According to the *Pharmaceutical Journal*, this chairman "declares that unless British firms are allowed to recover the cost of research in the products they sell, they cannot continue to spend money on research. This could only mean that more and more specialties would have to be brought from abroad, principally the United States and Germany, where immensely more money is spent on research than in this country. . . . If the Minister's plans result in the Service becoming unremunerative to the pharmacist on the present terms then the dispensing fee must be raised to keep him on an even financial keel."

Toxicity of Phenylbutazone.—The toll of phenylbutazone toxicity mounts steadily, and within a fortnight the *Lancet* and *British Medical Journal* have published four reports on the subject. In a series of 109 patients suffering from various rheumatic conditions, J. R. Nassim and T. Pilkington (*Brit. M. J.* 1:1310 [June 13] 1953) report that 46 persons suffered from toxic reactions severe enough to necessitate stopping the therapy of a daily dose of phenylbutazone from 0.2 to 1.2 gm. (average, 0.6 gm.). The reactions included severe anorexia and upper abdominal pain, dryness of the mouth and throat leading to ulceration, punctate erythematous rashes, cervical glandular enlargement, vertigo, and granulopenia. There were no fatalities. According to J. C. Leonard (*Brit. M. J.* 1:1311 [June 13] 1953) 356 toxic effects, occurring in 1,526 patients treated with phenylbutazone, have been recorded in the literature, showing an incidence of 22%. He reports two new cases: a fatal one of aplastic anemia and a case of agranulocytosis. In the *Lancet* (1:1227 [June 20] 1953) Derek Freeland and co-workers record an incidence of 67 reactions in a series of 164 patients (40%) on a daily dose of 200 mg. or less. In half the cases the toxic effects wore off although the therapy was continued. There were no fatalities. Another fatality is reported by Nancy V. Dilling (*Lancet* 1:1230 [June 20] 1953) following the development of a complete agranulocytosis in a 53-year-old woman who had been treated for a relatively short period on a daily dose of 600 to 400 mg.

PARIS

Detection of Tuberculin Allergy.—This technique for detection of tuberculin allergy is essentially a simplification by Drs. Besson, Dassonville, and Giraud of the "Finnish" process. They reported to the National Academy of Medicine the results of their studies of 4,000 intradermal reactions. The following technique was employed: Sterile individual short bevel needles 15 to 20 mm. long were used for intradermal injection. A 1 cc. vial of tuberculin from the Pasteur Institute is used. The skin of the left acromioclavicular region was cleansed with alcohol; the needle, held by the right thumb and forefinger, was dipped in the small vial of tuberculin and with the skin held tight between the left thumb and forefinger, a tiny droplet of tuberculin was deposited on it by a left to right wiping up motion. Then, by an inverse movement, the needle was pushed almost tangentially to the skin, only the bevel penetrating the dermis through the deposited droplet of tuberculin. The amount of tuberculin injected is about 0.25 mg. The authors stress that it is necessary to always use needles of the same bore and length of bevel. The results are read on the seventh day. Positive reactions are evidenced by erythematous papules from 2 to 10 mm. in diameter. Occasionally more intense reactions are noted. The reading of the reaction by sight and palpation is comparable to that of the Mantoux reaction. The authors used this method for the detection of allergy in 1,500 children before and after vaccination with BCG. They observed 95% of vaccinated children have positive reactions two months after vaccination by scarification.

Prophylaxis of Poliomyelitis.—A team of scientists of the Casablanca (Morocco) Pasteur Institute have reported on their research on the poliomyelitis virus in the rabbit. They announced their results to the National Academy of Medicine and, according to them, this rabbit virus is innocuous to man. When taken orally by man, it caused no accidents and was present in the stools for 100 days. After several experiments on the possible effect of this virus on humans, oral vaccination was undertaken in the beginning of 1953 on 5,699 children in two quarters of Casablanca where cases of poliomyelitis had been reported.

Determination of Heparin Blood Levels.—Protamine sulfate neutralizes the antithrombin activity of heparin. Starting from this fact, J. L. Baumont evolved a new method for determining the heparin contents of blood and other body fluids. The rapidity of blood coagulation depends solely on the thrombin, fibrinogen, and antithrombin content. The only antithrombin activity of heparin is neutralized by protamine sulfate. The new method of thrombin determination consists of measuring the amount of thrombin by which an increased prothrombin time is brought back to a stable level. The new technique detects as little as 0.005 parts per thousand of heparin in the plasma. The author reported on this technique at the meeting on March 19 of the French Society for Hematology. He stressed that it offers the advantages of being more sensitive and of yielding fewer errors than other methods.

Vegetable Juices.—In a recent issue of the *Monthly Bulletin of the Ministry of Health and the Public Health Laboratory Service* (12:78 [April] 1953) H. E. Magee published an analysis of some of the better known constituents of vegetable juices. These are summarized in the following table, in which the figures in parentheses represent the content of the vegetable (as opposed to the juice):

Juice	Total Sugars (as Glucose) Grams per 100 Ml. (Gm.)	Iron, Mg. per 100 Ml. (Gm.)	Calcium, Mg. per 100 Ml. (Gm.)	Vitamin B_1, Mg. per 100 Ml. (Gm.)
Broccoli leaves	3.00 (0.4)	0.60 (1.52)	18.70 (160)	15.0
Cabbage	4.17 (8.3)	1.02 (1.0)	16.90 (65)	75.0 (75)
Carrots	7.11 (5.4)	0.30 (0.6)	0.49 (48)	30.0 (60)
Celery	2.08 (1.2)	0.43 (0.6)	0.62 (52)	15.0 (30)
Kale	3.71	1.60 (2.5)	11.60 (200)	15.0 (120)
Melon	4.33	0.42	0.40	30.0
Parsley	0.44 (8.8)	1.12 (8.0)	6.30 (325)	30.0 (120)
Spinach	1.85 (1.2)	1.02 (4.0)	0.75 (595)	Nil (100)
Tomato	3.06 (2.8)	0.08 (0.4)	4.05 (13)	15.0 (60)
Watercress	0.20 (0.6)	2.12 (1.6)	2.90 (222)	30.0 (120)

In the case of vitamin C, only kale juice was found to have any appreciable amount, 46 mg. per 100 ml.; this was probably due to the absence of oxidases or that of antioxidases. Investigations showed that the vitamin C in many vegetable juices was quite unstable. The reaction of all the juices examined was very close to neutrality, and it was found that they practically all had a high buffering capacity. When milk, which is well known for its buffering capacity, was used as the standard, spinach juice was found to surpass it, while the juices of cabbage, kale, and parsley were not far behind. The comment is made that "the high buffering capacity of the juices suggests that they might be valuable in the treatment of hyperchlorhydria." It is noted that the reaction of the fresh juices, and their buffering capacities, would favor bacterial growth at suitable temperatures; "perhaps the most to be feared is *B.* botulinus." Juices can be preserved in three ways: "(1) by ensuring scrupulous cleanliness of the vegetables and then keeping the juice at refrigerator temperature from the time of expression until consumption, (2) by pressure sterilization, and (3) by lowering the pH to 4.2 or less, followed by low temperature pasteurisation." Attention is also drawn to the significant amounts of minerals in vegetable juices and to recent work indicating that some green vegetables, and their juices, contain appreciable amounts of some of the essential amino acids.

On the relative merits of juices as compared with whole vegetables, the view is expressed that "for the healthy person then, vegetable juices can hardly be regarded as a substitute for whole vegetables and their place in the normal diet would seem to be merely as an appetiser or cocktail." On their therapeutic value the position is summed up as follows: "Claims are made that various juices in amounts up to 500 ml. daily are beneficial in hyper-tension, certain types of cardiovascular and kidney disease and in obesity, but it is not clear to what extent other elements in the therapy employed, e. g., low calorie diets and low sodium chloride, were contributory factors. Good effects have also been ascribed to the juices in rheumatic, degenerative and toxic states, and they are probably attributable to their all-around protective action. The evidence indicates that good results are to be expected from large amounts of juices (up to 1 litre daily) in the treatment of peptic ulceration. But they have also given good results in the treatment of diarrhoea, colitis and toxaemia of gastro-intestinal origin."

Antibiotic Production in the United Kingdom.—It has just been reported that the output of penicillin in this country in April constituted an all-time record: the average weekly output was 2,136,600 megaunits. This compares with 1,296,000 megaunits in 1952 and 723,700 megaunits in 1951. For the first four months of the year exports of penicillin salts and preparations amounted to 17,500,000 megaunits, compared with just over 12 million megaunits in the same period last year. In February, 1953, the price was further cut by 3s.9d. to 21s.3d. per 5 megaunits. In reporting these figures, the *Financial Times* also announces an interesting development in the antibiotic field, whereby a British company "has made an arrangement with an American company to make the crude broth from which aureomycin is extracted," and it is expected that a substantial output will be reached by September. According to the same course, "this will make the United Kingdom independent of the imported crude which is now coming from the United States. . . . The implications . . . are many. It could mean that aureomycin will be available to doctors on the same basis as penicillin when it becomes wholly made in England. At present these drugs [i. e., aureomycin and oxytetracycline] can only be used by hospitals and doctors in special cases."

Ambulance Service Costs.—Figures just issued for the year ended March 31, 1952, show that the Ambulance Service cost the country £8,608,828 during this year. An analysis of this figure shows that 56.4% was spent on the operational staff, 20.3% on the fueling and maintenance of vehicles, 6% on provision of vehicles, 2.8% on maintenance of such things as buildings and furniture, 1.2% on provision of land and buildings, and 13.3% on other expenditures, including administrative expenses. During the year the service conveyed 11 million patients, and the mileage covered was 92 million miles. This compares with 9 million patients and 89 million miles in the previous year. The average cost per patient fell from 15s.6d. to 15s.2d., and the average number of miles run per patient fell from 9 to 8.3. The number of ambulances and cars in use was 4,411. In addition a large number of private cars were available on a voluntary basis through the Hospital Car Service, and 15,000 patients traveled by rail under arrangements made by local health authorities.

The Nation's Drug Bill.—The serious view that the government takes of the rising drug bill is well demonstrated by the fact that Mr. Lan Macleod, the Minister of Health, attended in person the Annual Conference of Local Committees of the British Medical Association in order to appeal for the support of the medical profession in his efforts to reduce this unruly item without disciplinary action. He described the rising cost of the drug bill as one of the gravest and most urgent problems that confronted the National Health Service. He said that the exchequer could not go on paying an annual bill of something like 40 million pounds for drugs prescribed by general practitioners (when the whole range of dressings and appliances prescribed is considered, the figure is nearer 60 million pounds) unless the drugs were all essential for the proper treatment of patients.

He advanced two major reasons for the increase in the drug bill from £31,500,000 in 1949-1950 to an estimated figure of £46,500,000 in 1953-1954: (1) an increase in the total number of prescriptions dispensed, over 200 million a year (the latest figures just announced are those for August, 1952: 12,953,542 at a total cost of £2,709,428, or an average of 50.2d. per prescription), and (2) an increase in the average cost of prescriptions from 2s.9d. in 1948-1949 to an estimated 4s.3d. in 1953-1954, due to (*a*) the introduction of new valuable but expensive drugs, (*b*) the rise in the ingredient prices until this year, though some drugs, e. g., some of the antibiotics, were considerably cheaper, and (*c*) the prescribing of an increased proportion of proprietary preparations (in 1952, proprietaries represented 26% of the total number of prescriptions, 52% of their total ingredient cost, and 44.5% of their total cost).

He quoted a few examples of how widespread prescribing of proprietary, as opposed to official (or standard), preparations was pushing up the drug bill. One was a proprietary reducing preparation, which, if prescribed by its standard name, would have produced a savings of about £242,000 in 1951. The second included proprietary tablets containing aspirin, acetophenetidin, and codeine, which cost 6s.3½d. for 50, compared with 2s.11d. for 50 of the comparable standard preparations. The third was proprietary asthma inhalants, which might cost four to six times as much as a standard inhalant, with no evidence that there was anything to choose between proprietary and standard preparations from the point of view of therapeutic efficacy. It has been estimated that a sum of around £50,000 could be saved if comparable standard preparations were used instead of proprietary preparations in the treatment of peptic ulcer and heart disease.

The minister then proceeded to indicate that practical ways in which practitioners could assist him in reducing this expenditure on drugs. 1. They could make more careful use of "National Formulary" preparations by referring to the two tables of proprietary preparations in the "Formulary" (those for which an identical preparation is available in the "Formulary" and those for which there is a "Formulary" preparation substantially the same or reputed to have an analogous therapeutic effect) and always prescribe a "Formulary" preparation unless there was a special reason to do otherwise. Incidentally, the Minister pointed out, the "Formulary" preparations were recommended by experts of the medical and pharmaceutical professions (quite independently of the Ministry of Health), and there was no reason to regard them as inferior simply because they were cheaper. 2. Practitioners could satisfy themselves before prescribing a proprietary preparation not included in the two "Formulary" lists that there were adequate grounds for accepting its therapeutic value in treating the particular condition for which it was prescribed. 3. Practitioners could resist pressure from patients to prescribe particular preparations that had been recommended or that they had read about in technical or semitechnical journals. 4. Practitioners could also refrain from prescribing unreasonably large quantities of a drug or dressing.

The steps being taken by the Ministry included the issuing of a price list of "Formulary" preparations and proprietary preparations listed in the "Formulary" or occupying a high place on the basis of frequency of prescribing. Physicians would thus be made fully aware of the cost of what they were prescribing. In addition, there would shortly be published the Cohen committee's classification of proprietary preparations. This would enable physicians to be told the names of preparations in the two "doubtful" categories covering drugs that were not of proved therapeutic value and might not be prescribed. Simultaneously the Ministry was proceeding, in consultation with the manufacturers, to investigate the production costs of selected proprietary preparations in the categories that the Cohen committee considered prescribable subject to satisfactory price arrangements.

While the problem may be a relatively simple one from the point of view of the Minister of Health, the implications, if he succeeds in his economy drive, are far from simple. One of the most serious implications is the effect on the research budgets of the leading pharmaceutical houses. The Minister has consistently paid tribute to the considerable amount of research done by these companies, but he has tended to take the line that his major interest is the drug bill and that research and, incidentally, export sales are not his responsibility. That the pharmaceutical companies are becoming worried about the future of their research departments is well brought out in the recently published annual report of the chairman of the company owing the largest chain of retail pharmacies in the United Kingdom. According to the *Pharmaceutical Journal*, this chairman "declares that unless British firms are allowed to recover the cost of research in the products they sell, they cannot continue to spend money on research. This could only mean that more and more specialties would have to be brought from abroad, principally the United States and Germany, where immensely more money is spent on research than in this country. . . . If the Minister's plans result in the Service becoming unremunerative to the pharmacist on the present terms then the dispensing fee must be raised to keep him on an even financial keel."

Toxicity of Phenylbutazone.—The toll of phenylbutazone toxicity mounts steadily, and within a fortnight the *Lancet* and *British Medical Journal* have published four reports on the subject. In a series of 109 patients suffering from various rheumatic conditions, J. R. Nassim and T. Pilkington (*Brit. M. J.* **1**:1310 [June 13] 1953) report that 46 persons suffered from toxic reactions severe enough to necessitate stopping the therapy of a daily dose of phenylbutazone from 0.2 to 1.2 gm. (average, 0.6 gm.). The reactions included severe anorexia and upper abdominal pain, dryness of the mouth and throat leading to ulceration, punctate erythematous rashes, cervical glandular enlargement, vertigo, and granulopenia. There were no fatalities. According to J. C. Leonard (*Brit. M. J.* **1**:1311 [June 13] 1953) 356 toxic effects, occurring in 1,526 patients treated with phenylbutazone, have been recorded in the literature, showing an incidence of 22%. He reports two new cases: a fatal one of aplastic anemia and a case of agranulocytosis. In the *Lancet* (**1**:1227 [June 20] 1953) Derek Freeland and co-workers record an incidence of 67 reactions in a series of 164 patients (40%) on a daily dose of 200 mg. or less. In half the cases the toxic effects wore off although the therapy was continued. There were no fatalities. Another fatality is reported by Nancy V. Dilling (*Lancet* **1**:1230 [June 20] 1953) following the development of a complete agranulocytosis in a 53-year-old woman who had been treated for a relatively short period on a daily dose of 600 to 400 mg.

PARIS

Detection of Tuberculin Allergy.—This technique for detection of tuberculin allergy is essentially a simplification by Drs. Besson, Dassonville, and Giraud of the "Finnish" process. They reported to the National Academy of Medicine the results of their studies of 4,000 intradermal reactions. The following technique was employed: Sterile individual short bevel needles 15 to 20 mm. long were used for intradermal injection. A 1 cc. vial of tuberculin from the Pasteur Institute is used. The skin of the left acromioclavicular region was cleansed with alcohol; the needle, held by the right thumb and forefinger, was dipped in the small vial of tuberculin and with the skin held tight between the left thumb and forefinger, a tiny droplet of tuberculin was deposited on it by a left to right wiping up motion. Then, by an inverse movement, the needle was pushed almost tangentially to the skin, only the bevel penetrating the dermis through the deposited droplet of tuberculin. The amount of tuberculin injected is about 0.25 mg. The authors stress that it is necessary to always use needles of the same bore and length of bevel. The results are read on the seventh day. Positive reactions are evidenced by erythematous papules from 2 to 10 mm. in diameter. Occasionally more intense reactions are noted. The reading of the reaction by sight and palpation is comparable to that of the Mantoux reaction. The authors used this method for the detection of allergy in 1,500 children before and after vaccination with BCG. They observed 95% of vaccinated children have positive reactions two months after vaccination by scarification.

Prophylaxis of Poliomyelitis.—A team of scientists of the Casablanca (Morocco) Pasteur Institute have reported on their research on the poliomyelitis virus in the rabbit. They announced their results to the National Academy of Medicine and, according to them, this rabbit virus is innocuous to man. When taken orally by man, it caused no accidents and was present in the stools for 100 days. After several experiments on the possible effect of this virus on humans, oral vaccination was undertaken in the beginning of 1953 on 5,699 children in two quarters of Casablanca where cases of poliomyelitis had been reported.

Determination of Heparin Blood Levels.—Protamine sulfate neutralizes the antithrombin activity of heparin. Starting from this fact, J. L. Baumont evolved a new method for determining the heparin contents of blood and other body fluids. The rapidity of blood coagulation depends solely on the thrombin, fibrinogen, and antithrombin content. The only antithrombin activity of heparin is neutralized by protamine sulfate. The new method of thrombin determination consists of measuring the amount of thrombin by which an increased prothrombin time is brought back to a stable level. The new technique detects as little as 0.005 parts per thousand of heparin in the plasma. The author reported on this technique at the meeting on March 19 of the French Society for Hematology. He stressed that it offers the advantages of being more sensitive and of yielding fewer errors than other methods.

CORRESPONDENCE

ARACHNIDISM

To the Editor:—In THE JOURNAL (152:609 [June 13] 1953) Maretic reports a case of arachnidism treated, after 24 hours of symptoms, by a single dose of 80 mg. of cortisone, with apparent cure. While cortisone is helpful in some cases of arachnidism, it fails in others, and in my experience it cannot be recommended for the routine treatment of these cases. In a series of 35 cases in which I had the opportunity to try various treatments, I feel that specific antivenin is the only adequate form of treatment. Although this product has not been available lately, its production is now being resumed. In my cases not treated by antivenin, the duration of symptoms lasted from 12 to 211 hours. It is this natural variation in the duration of symptoms that accounts for the apparent success of various treatments published in isolated case reports, rather than the effectiveness of the recommended medication. One case illustrates the failure of cortisone and corticotropin in arachnidism. A 16-year-old white boy was bitten on the finger by a black widow spider on the afternoon of Aug. 14, 1952. He was hospitalized at 9 p. m. that night and discharged apparently well the morning of Aug. 17. While in the hospital, his treatment consisted of the administration of 50 units of corticotropin (ACTH), 250 mg. of cortisone, 200 mg. of meperidine (Demerol) hydrochloride, and two ampuls of calcium gluconate. These medications were given according to the recurrence of pain. After his discharge from the hospital and 16 hours after the last dose of cortisone was given, there was an exacerbation of acute symptoms. The boy was given one ampul of antivenin, and relief was permanent.

LEPROSY

To the Editor:—The article "Alopecia Leprotica: Its Relationship to Transmission of Leprosy," which appeared in THE JOURNAL, June 13, 1953, page 573, elicits some comments. During my 19 years in China, I was particularly interested in the study of leprosy. I had ample opportunity to investigate several aspects of the problem in the course of my visits to leprosaria throughout the Far East, in my clinic work at the National College of Medicine, and in my work as clinical chief of the National Leprosarium in Shanghai. I have never seen alopecia of the scalp in neural leprosy in the Chinese, although it is not infrequent among the Japanese. This racial factor of the clinical manifestation of leprosy is striking; for example, neural abscesses occur only among Hindus, lazarine leprosy is observed only in Cuba, and spotted leprosy of Lucio has been described only in Mexico. On the other hand, alopecia of the scalp and of the eyebrows in lepromatous leprosy occurs not only in China but in other parts of the world where leprosy is endemic and where shaving a child's scalp is not practiced. One of the leading leprologists, Robert Cochrane ("Practical Textbook of Leprosy," New York, Oxford University Press, 1947, p. 60), makes the following statement: "While some authorities state that the scalp is not affected in leprosy, in certain races, particularly the Mongolian and European, a leprous alopecia is sometimes seen." Alopecia in lepromatous leprosy is due to the lepromatous infiltration of the hair follicles and the hair papillae that leads to either atrophy or destruction of the latter or both. In such instances, leprosy bacilli can be found without difficulty, but they cannot be found in cases of hair loss of the eyebrows or the scalp resulting from neurotrophic disturbances (neural leprosy). The extent and severity of the alopecia in lepromatous leprosy depends largely on the degree of the lepromatous infiltration. This has been demonstrated by numerous investigators. On the other hand, up to the present time, exact clinical data and experimental evidence are unavailable in the literature dealing with the mode of the progress of the disease. It seems unconvincing, therefore, to state that the involvement of the scalp is related to "the habit of shaving the scalp of newborn infants." Also, alopecia of the scalp does not necessarily develop at the site of the assumed primary focus but can and does develop in persons in whom the infection entered any skin area other than the scalp. It is speculative to make statements regarding the development and the method of progress of leprosy on the basis of the clinical material presented. The "histological verification" of the clinical lesions as lepromatous does not conform with the usual concept of lepromatous tissue changes. A microscopic picture showing "marked lymphocytic infiltration, persistent involvement of the sweat glands, and the presence of varying numbers of macrophages" is insufficient to label a section lepromatous, despite the presence of acid-fast bacilli.

The relative immunity of adults is well known. The author's terse statement, however, "that most reported cases are open to question," without indicating a valid reason, must be challenged. While early childhood is the most susceptible period, I have observed adults, mostly missionaries, who contracted the disease in China or the Philippine Islands, yet, none of these patients lived in an area in which leprosy was endemic during their childhood.

MEDICAL ASSOCIATION OF THE ISTHMIAN CANAL ZONE

To the Editor:—The Medical Association of the Isthmian Canal Zone is unique in that, while there are a certain number of permanent members who reside in the Canal Zone or the Republic of Panama, a large percentage of the membership is made up of service officers and others who spend a few years in the Zone and then proceed to posts in the United States or abroad. The 558th meeting of the Medical Association of the Isthmian Canal Zone was held recently at the Palo Seco Leper Colony, Canal Zone. The meeting took the form of a "Symposium on Leprosy" arranged by the scientific committee under the chairmanship of Dr. Jack Strumpf. A school bus was secured by Lieutenant Colonel Beaudry of Gorgas Hospital to supplement private cars in conveying the large group of physicians to the leprosarium. Both the junior and senior physicians were eager to avail themselves of this special opportunity that they may never have again after leaving the Zone. We made a tour through the beautiful grounds on the shore of the Pacific and through the buildings and patients' quarters, before supper was served. Then came a short business meeting and the symposium. Dr. Ezra Hurwitz, superintendent of the leprosarium, was the moderator. Having a little over 120 patients, Dr. Hurwitz was able to choose interesting cases of leprosy of all types and stages. Following his talk and a demonstration of cases, a panel of physicians from the Army, Gorgas Hospital, and the Health Director's Office continued the discussion from the viewpoint of the various specialties. Those on the panel were Col. Francis E. Council, Col. Earl C. Lowry, Col. Louis S. Leland, Col. M. C. Davenport, and Lieut. Col. Edward J. Dehne and Drs. Amade V. Mastellari, Benjamin Boyd, and Walter G. Nelson, medical director, U. S. P. H. S.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Evidence: Admissibility of Results of Truth Serum Tests.—The defendant was convicted of murder and from such conviction appealed to the Supreme Court of New Mexico.

At the trial the defendant, after having made conflicting statements, offered to prove by narcoanalysis that his testimony that he did not kill the deceased was the true story. The evidence of a psychiatrist was taken, in the absence of a jury, to show that, when thiopental (Pentothal) sodium was administered to anyone in the proper amount and by one skilled in the work, the truth could be obtained from the person to whom the drug had been administered and that such was a fact generally recognized in medical circles. Another psychiatrist was called as a witness to refute this testimony, however, and he did so in a manner that was convincing to the trial judge. The testimony offered by the defendant was, therefore, rejected by the trial court on the ground that such tests were not reliable or generally approved and accepted by members of the medical profession specializing in psychiatry. Among other assignments of error, the defendant contended that the trial judge should have permitted the psychiatrist to testify that he gave sodium Pentothal to the defendant and then questioned him on many points, and as a result of this examination it became very clear that the defendant did not kill the deceased, that the confessions he made were false, and that he told a true and accurate story of his connection with the case that was identical in all respects to the story he told on the witness stand.

The defendant frankly states that no court, so far as he knows, has held such testimony admissible, but he says it is time some court did so. He quoted from Herzog's "Medical Jurisprudence," § 472, on the results obtained by scopolamine as a crime detector in which instances are given of the truth having been obtained; the article supports its use. It admits, however, that wrong answers may be obtained if insufficient amounts of the drug are administered and that wrong answers may be obtained if the subject has either not yet reached the examination stage or has passed out of it.

On the other hand, the state produced an article entitled "The Judicial Use of Psychonarcosis in France" printed in the *Journal of Criminal Law and Criminology* (40:370), from which we quote:

"Professor Delay and the majority of Psychiatrists assert that psychonarcosis is not able to check the determined will of concealing a precise point, while Dr. Scharlin, chief of the Neuropsychiatric department of the Regional Hospital Department of Bescancon, gives the following results of about a hundred experiments which have been undertaken under conditions similar to those which are met with in judicial matters. In 12% cases the results prove completely satisfactory; for instance, a miner subjected to narcosis said the following: 'It's queer your stuff; makes one talk all right, the murderers need to be mightly careful with you.' In 30% cases the examination is only able to obtain precisions on secondary details, as the will controls the important answers; finally, in about 60% cases, the results are completely negative."

The article further states: "In France, psychonarcosis has never been used for obtaining a suspect's confession, except in a few experiments which have no judicial value."

The *American Journal of Psychiatry* (107:586-593 [Feb.] 1951) has an article by Frederich C. Redlich, M.D., professor of psychiatry, Yale University School of Medicine, Leonard J. Ravitz Jr., M.D., and George H. Session, LL.D., Lines Professor of Law, Yale Law School, on experiments made on nine persons who received amobarbital (Amytal) sodium intravenously and were questioned while under its influence. Each of the subjects had a true and a cover story. We quote from page 589 of the article:

"It is of interest that the 3 subjects diagnosed as normal (i. e., persons who perform adequately in their various functions, have good defenses and no highly pathological characteristics) maintained their cover stories. Of the 6 subjects diagnosed as neurotic, 2 promptly revealed the true story; 2 made partial admissions, consisting of a complex pattern of fantasy and truth; one admitted what most likely was a fantasy as truth; and the one obsessive-compulsive individual maintained his cover story except for one parapraxia, (faulty or blundering action). We were particularly struck by the fact that G. U. and S. S., who confessed readily, had strong unconscious guilt feelings.

"The fantasies under sodium amytal can be understood only in the light of intimate knowledge of the subjects' unconscious processes. Such fantasies produced during the sodium amytal interview at times had the character of a confession as in the case of K. D., who confessed to beating the plumber, while in reality probably only the subject was beaten. Such fantasies are similar to dreams and daydreams; at times they have a highly symbolic character as in C. Y. when she spoke of the disgusting beard of a sexualized father figure, while this particular person in reality had no beard. . . ."

The Supreme Court of Missouri in State v. Hudson, Mo. Sup., 1926, 289 S.W. 920, refused the offered testimony of a physician that he had administered truth serum to a defendant and the answers made to questions asked while under the influence of the drug. The court, in an interesting opinion, rejected the claim of error on account of the refusal to admit such testimony, classifying it as a self-serving declaration and unworthy of consideration in the present state of human knowledge.

We agree that the courts should keep step with scientific developments but believe the statements in State v. Bohner, 210 Wis. 651, 246 N.W. 314, 317, 86 A.L.R. 611, are applicable to this case and reflect our present views. We quote:

"It seems to us that this statement offers little comfort to one who contends that this device is past the experimental stage. While it may have some utility at present, and may ultimately be of great value in the administration of justice, it must not be overlooked that a too hasty acceptance of it during this stage of its development may bring complications and abuses that will over-balance whatever utility it may be assumed to have. The present necessity for elaborate exposition of its theory and demonstration of its practical working, in order to convince the jury of its probative tendencies, together with the possibility of attacks upon the soundness of its underlying theory and its practical usefulness, may easily result in a trial of the lie detector rather than the issues in the cause. If the defendant in a criminal case is to be permitted to have tests taken outside of court and then produce expert testimony as to the results of the tests when these are favorable to him, without the necessity of taking the stand or submitting to tests by the prosecution, the way would seem to be open to abuses that would not promote the cause of justice. It is our conclusion that the refusal of the trial court to admit this testimony was not error."

Statements made by a defendant while under the influence of thiopental were held inadmissible as self-serving and hearsay by the District Court of Appeals of California in People v. McNichol, 100 Cal. App. 2d 554, 224 P. 2d 21.

We conclude that the trial court did not err in refusing to admit the testimony of Dr. Gore by which it was sought to show the questions asked the defendant and answers made by him while he was under the influence of the drug.

Until the use of the drug as a means of procuring the truth from persons under its influence is accorded general scientific recognition, concluded the Supreme Court of New Mexico, we are unwilling to enlarge the already immense field in which medical experts, apparently equally qualified, express such diametrically opposite views on the same facts and conditions, to the despair of the court reporter and the bewilderment of the fact finder.

Other contentions of the defendant were also overruled and the judgment of conviction was, therefore, affirmed. *State v. Lindemuth, 243 P. (2d) 325 (New Mexico, 1952).*

Hospitals in General: Liability for Injuries Caused by Drunken Patient.—This was an action for damages for personal injuries alleged to have been sustained by the plaintiff as a result of the defendant hospital's negligence in failing to protect plaintiff from injuries caused by the violence of another patient who was intoxicated. From a judgment of the trial court that denied the plaintiff's motion to have a new trial and to vacate a directed verdict in favor of the defendant, the plaintiff appealed to the Supreme Court of Minnesota.

The plaintiff was admitted to the defendant hospital for an appendectomy and, after the operation, was placed in a six-bed ward to convalesce. On Dec. 21, the stitches were removed in anticipation of his release from the hospital the next day. On the evening of that day, another patient, Red Hanson, came into the plaintiff's ward in such an intoxicated condition that he was staggering back and forth. Red threw himself onto plaintiff's bed and in so doing pushed it until it was almost against the next bed. After pulling the sheets off plaintiff, Red grabbed plaintiff's fingers and twisted them so as to cause pain. When plaintiff protested, Red became angry and took off his nightgown, which he rolled into a ball and threw at another patient. After 20 to 30 minutes of such disturbance, plaintiff asked Red to leave the room. Red said that he would if the plaintiff would help him put on his bathrobe. While plaintiff was assisting him, Red suddenly struck plaintiff in the abdomen adjacent to the appendectomy incision. As a result of the blow, plaintiff suffered considerable pain and injury, for which he seeks by this action to recover damages from the hospital on the theory that it was negligent in permitting Red to move about the hospital in an intoxicated condition, thereby endangering plaintiff's safety. The evidence indicated that on other occasions Red had staggered into the plaintiff's ward in a drunken condition, and it further appeared that in order to reach the plaintiff's ward Red had to walk the full length of the hospital. In short, there was evidence from which a jury could reasonably find that the defendant hospital knew, or ought to have known, that Red, as one of its patients, was wandering about the hosptial in an intoxicated condition; but there is no satisfactory evidence that it actually knew that, when intoxicated, he was possessed of vicious tendencies.

A private hospital, said the Supreme Court, although it is not an insurer of the safety of a patient, must exercise such reasonable care for the protection and well-being of a patient as his known physical and mental condition requires or as is required by his condition as it ought to be known to the hospital in the exercise of ordinary care. As to the danger reasonably to be anticipated from the acts of another person under the hospital's control, the reasonable care to be exercised must always be in proportion to the patient's inability to look after his own safety. The standard of reasonable care is that which would be exercised by a reasonably prudent person under the same or similar circumstances and does not require the taking of precautionary measures to avert a danger that a reasonable person would not anticipate as likely to happen. Thus, the court continued, a hospital that accepts patients who are either insane or suffering from some other mental disorder under such circumstances that the hospital either has actual knowledge, or the circumstances are such that by the exercise of reasonable care it should have known, of the patient's dangerous and assaultive tendencies has been held liable to other patients for injuries inflicted on them by such patient. The law from ancient times has recognized that an intoxicated person is likely to cause injuries not only to himself but to others.

In the light of the unpredictable behavior of an intoxicated person as a well-recognized source of danger to others, concluded the Supreme Court, it follows that where defendant hospital knew, or in the exercise of reasonable care ought to have known, that one of its patients was so intoxicated as to stagger when walking, it ought to have anticipated—although it did not actually know that the patient was vicious or aggressive when drunk—that to permit him to wander about the hospital unguarded was likely to result in injury to other patients, and it is liable for any injury that proximately resulted from his intoxicated condition, although it could not have anticipated the particular injury that did happen.

Accordingly the trial court's order refusing to grant a new trial and its directed verdict in favor of the defendant hospital were reversed. *Sylvester v. Northwestern Hospital of Minneapolis, 53 N.W. (2d) 17 (Minnesota, 1952).*

Admissibility in Evidence of Chemical Tests for Intoxication.—The defendant was convicted of manslaughter, and from the judgment of conviction he appealed to the criminal court of appeals of Oklahoma.

At the trial, Lieutenant Hopper of the Oklahoma City police department testified that he had been with the department over 20 years and that at about 7:20 the evening that the defendant was arrested, defendant was brought to him to take the drunkometer test. He said: "The officers brought the man in and asked me to give him the Drunkometer test. I explained the Drunkometer machine to the gentleman and then told him that we would give him a test if he would consent to it, to blow up the balloon to ascertain how much alcohol he had in his blood stream. He did not object. He blew up the balloon and I gave the test." Lieutenant Hopper further testified that no threats were made or promises made and that the test was strictly voluntary. The lieutenant had the drunkometer in court and explained in detail how it operated. He stated that it showed that the defendant had 0.155 of 1% alcohol in his blood stream.

Lieutenant Gunn of the Oklahoma City police department testified that he had been with the department over 20 years, that he was a graduate of the Northwestern University Traffic Institute, and that he had received about 40 hours training in the fundamentals of chemistry and the physiological effect of alcohol on the human body at the University of Oklahoma School of Medicine. He studied under Dr. Harger, inventor of the drunkometer, when at Northwestern University. He stated that the National Safety Council, the American Medical Association, the American Bar Association, the Federal Bureau of Identification, the International Association of Chiefs of Police, and others had endorsed the drunkometer test. He stated that in 1947, the Oklahoma City police department acquired a drunkometer. To be sure of its reliability, they turned the instrument over to the dean of the Oklahoma School of Medicine, who kept it a number of months to conduct experiments and make tests to prove its reliability. He stated that the instrument was found to be accurate. The police department then conducted around 500 tests on drunks and on persons who had only onion, Sen-sen, or garlic, on the breath or on persons who had taken whiskey in the mouth and then spit it out or who had used a mouth wash. Lieutenant Gunn stated that he had conducted a school in the Oklahoma City police department on chemical tests for intoxication and physiological effects of alcohol on the human body as shown by the drunkometer and had taught the use of the drunkometer. He also said that if a person shows 0.15 of 1% of alcohol in his blood by weight he is definitely under the influence of alcohol and he has lost normal ability to control himself or to control his actions as would a normal person.

Dr. Shoemaker, professor of pharmacology at the University of Oklahoma School of Medicine, testified concerning the reliability of the drunkometer test for determining the amount of alcohol in a person's blood stream. He gave it as his expert opinion that a person shown to have 0.155% of alcohol by weight in his blood stream would show definite effects of alcohol. He stated that the amount of alcohol would slow such person's thinking to a marked degree; that he would have a slurring of his speech and a staggering gait; and that there would be a not very marked, but a definite loss of muscular coordination and loss of control of movements. He stated to get 0.155% by weight of alcohol in one's blood, a person would have to consume six or eight ounces of 100 proof whiskey, or approximately 12 bottles of 3.2 beer.

The Criminal Court of Appeals said that in a recent case (*Toms v. State, 239 P. (2d) 812; J. A. M. A.* **150**:1424 [Dec. 6] 1952) it approved the test in cases in which the accused voluntarily took the same. In this case, evidence indicated that the defendant had voluntarily taken the test and that there was no error in the record. Accordingly the evidence was admissible and the judgment of conviction was affirmed. *Lombness v. State, 243 P. (2d) 389 (Oklahoma, 1952).*

Dermatitis Venenata Due to Native Woods.—A man, aged 59, attributed his generalized dermatosis and loss of weight to woodworking. There was no improvement during the first month of hospitalization and in the following months itching, chilliness, and sleeplessness became more annoying. Other disturbances were loss of weight, enormous enlargement of the superficial lymph nodes, and alopecia of the scalp and axillae. Repeated histological examination ruled out cutaneous lymphoblastoma. The allergic dermatitis and generalized adenopathy subsided after six months of hospitalization. The patient then worked only with poplar wood, and one week later he again had generalized dermatitis venenata. Presumably in the beginning a subacute dermatitis of the hands and forearms was due to sawdust of poplar. This dermatitis became generalized, and for months it simulated cutaneous lymphoblastoma. The second attack and the positive reactions to patch tests proved the sensitizing capacity of poplar sawdust. Furniture makers are exposed to heartwood, the central portion of the tree, which contains substances that are allergenic for some persons. The major components of wood, such as cellulose and lignin, are not at fault, but rather the resins, terpenes, oils, phenols, tannins, coloring matter, nitrogen-containing and acetyl-containing substances, and formic acid. Acacia, alder, ash, beech, birch, chestnut, cedar, creosote bush, elm, maple, mesquite, oak, pine, poplar, prune, and spruce are the native woods that are cutaneous sensitizers. Poplar produced allergic reactions quite frequently in the author's practice, but generally men showed no sensitization to sawdust for many years. Dermatitis venenata due to native woods usually had its onset between the ages of 40 and 60 years. Several workers became sensitized to a foreign wood and later to a native one, or vice versa. One patient became sensitized to four woods. He was forced to give up the sawing of wood but was able to handle the finished wood. Sawdust and fragments of wood produced by machine tools have sharp edges and injure the skin when they strike it with sufficient force. Occasionally dermatitis following such a trauma is the forerunner of sensitization dermatitis.

Clinical Use of Triethylene Melamine.—Triethylene melamine, though similar to nitrogen mustard in its pharmacological effects, did not cause as much nausea and vomiting as nitrogen mustard. When the parenteral dose of triethylene melamine was doubled or given orally, it was equally effective. Bond and associates treated 75 patients with this drug. The drug was quite effective in 23 of 26 patients with chronic myelogenous leukemia of whom 18 were restored from invalidism to an active or productive life. In the initial course the authors employed 5 mg. tablets of triethylene melamine daily for 6 to 53 days, with an average of 20.3 days. The average total dose for the initial course was 101.5 mg. After satisfactory peripheral blood values were obtained, the patients were maintained on a dosage schedule averaging about 7.5 mg. per week. Tolerance to triethylene melamine was proportional to the white blood cell count. In Hodgkin's disease (14 cases) the results were not as favorable as those reported by other authors. Twelve patients with acute and subacute monocytic leukemia were treated with triethylene melamine, but the drug proved no more effective than any other agent. Its low toxicity, ease of administration, and flexibility of dosage merit its continued trial in this disease. In six of eight patients with chronic lymphocytic leukemia, a disease observed oftenest in elderly patients, treatment with triethylene melamine produced a satisfactory hematological response; lymphadenopathy, splenomegaly, and hepatomegaly were satisfactorily controlled in five patients. Chronic myelogenous leukemia and chronic lymphocytic leukemia were most effectively controlled by triethylene melamine. No significant hematological response was observed in four adults with leukolymphosarcoma. No significant benefits were observed in extramedullary lymphosarcoma, fibrosarcoma, Ewing's tumor, malignant melanoma, sarcoidosis, and polycythemia rubra vera. Secondary hemolytic anemia was temporarily controlled with triethylene melamine therapy in two patients. Toxic reactions to triethylene melamine were

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

minimal and consisted principally of anorexia, nausea, and vomiting. While triethylene melamine does not replace any other agent presently used in the treatment of blood dyscrasias and malignant lymphomas, it is a valuable adjunctive form of therapy. Its ease of administration and the flexibility of dosage schedule are most advantageous.

Cerebral Vascular Insufficiency and Localized Encephalopathy.—Although cerebral infarction without cerebral arterial occlusion and the reversibility of various acute manifestations of cerebral dysfunction have been explained for many years on the basis of cerebral vascular spasm, there is now considerable doubt concerning the role of spasm of the cerebral arteries in the production of localized encephalopathy. In this study attention is called to cerebral vascular insufficiency, a term that is applied to transient and reversible insufficiency of the cerebral blood flow, although damage to the brain may be permanent. Corday and his associates made electroencephalograms in the monkey after the carotid vessels were partially or completely ligated. When the blood pressure was lowered by bleeding the animal, focal electroencephalographic changes on the side of the ligation were similar to those found in hemiplegia. When the blood pressure was restored, the electroencephalographic records returned to normal. These changes were proved to be due to a drop in blood pressure rather than purely to anemia. Clinically, cerebral vascular insufficiency occurs in such conditions as hemorrhagic shock, surgical and traumatic shock, and hypotension due to sympathectomy, postural hypotension, carotid sinus stimulation, spinal anesthesia, and cardiac surgery. It can occur also as a result of surgical ligation of the carotid arteries, spontaneous thrombosis of the internal carotid artery, changes in gravitation, as in flying, and the use of antihypertensive drugs. The changes are transient if the blood pressure is restored to normal within a short period. If the blood pressure is not promptly restored in patients with cerebral arteriosclerosis or congenital anomalies, focal changes will be permanent. As in the heart in which coronary arteriosclerosis has occurred, it is important to maintain the cerebral blood pressure at normal levels, especially in the elderly patient with narrowing of cerebral arteries.

Pyretotherapy in Ophthalmoplegic Migraine.—Patrikios had reported in a previous study two cases in which unexpected elevation of the temperature resulted in rapid relief of ophthalmoplegic migraine after other therapy had failed. Then he used pyretotherapy in three other cases of ophthalmoplegic migraine with satisfactory results. In the first of these, in spite of interruption of the treatment, improvement has been maintained, and in the other two recovery was rapid and complete. Five new cases of ophthalmoplegic migraine are reported in which pyretotherapy proved effective. In his previous report the author believed the beneficial effect of fever therapy to be due to a vasomotor mechanism. He now feels that the beneficial action is the result of the general adaptation syndrome of Selye. The same mechanism may be invoked to explain the development of the ophthalmoplegic migraine itself, and would take into account the diversity and nonspecificity of its causes.

The Heart in Rheumatoid Arthritis.—This study is based on pathological material from 101 cases of rheumatoid arthritis. Although mitral stenosis is generally regarded as a consequence of rheumatic valvulitis, the significance of minor sclerotic and inflammatory changes in the heart is debatable. Pathologists may find stigmas of rheumatic inflammation in 60 to 93% of the adult population at necropsy. Three categories of rheumatic heart disease were watched for in this study: (1) frank rheumatic heart disease, such as mitral stenosis, rheumatic valvulitis, and myocarditis with formation of Ashoff bodies; (2) minor sclerosis of the valves accompanied by fibrosis of the leaflet with formation of thick-walled blood vessels; and (3) calcareous stenosis of the aortic valve. For purposes of comparison, data were obtained from consecutive necropsies performed on 1,154 persons over 19 years of age. The incidence of rheumatic heart disease was somewhat higher in the group with rheumatoid arthritis than in the general autopsy series, but it was far less than in most of the previous reports. The fact that in 66 of the 101 cases material was secured from the Armed Forces of Pathology suggests that persons who contracted rheumatic heart disease prior to the age of induction were excluded. Such military personnel, however, have a predisposition to develop rheumatic fever as the result of epidemics. Rheumatoid arthritis in a large proportion of cases is not established anatomically, because extensive dissection of the joints is not commonly performed at necropsy. If these and other limitations are recognized, the results of the present investigation suggest that in persons with rheumatoid arthritis there may be a somewhat higher incidence of heart disease that is indistinguishable from rheumatic heart disease than chance would dictate. A concept of heart disease specific to rheumatoid arthritis has been evolved recently. It is characterized by granulomatous inflammation similar to that found in the rheumatoid subcutaneous nodules. Such foci have been observed in the epicardium, adjacent myocardium, and the rings and leaflets of the mitral and aortic valves. In the present series, there was at least one case of rheumatoid nodule formation. Such frank rheumatoid heart disease appears to occur in about 1 to 3% of the cases of rheumatoid arthritis. The frequency with which evidences of healed pericarditis are found indicates that it is common in rheumatoid arthritis.

Seasonal Variation of Frequency of Acute Myocardial Infarction.—A survey was made of all cases of acute myocardial infarction seen in three Dallas hospitals during the years 1946 to 1951 inclusive. In each case the clinical record and the electrocardiograms were reviewed and whenever possible the time of onset established. Meteorological data were obtained from the Dallas weather bureau. Dallas has very hot summers, with maximum temperatures exceeding 95 F on most and 100 F on many days during July and August. The winters are relatively mild. The diagnosis of acute myocardial infarction was made in 1,666 instances, and in 1,386 cases the data appeared adequate to authenticate the diagnosis. There were 340 deaths, an over-all mortality rate (including some patients with multiple episodes) of 24.5%. Autopsy confirmation was obtained in 105 cases. Acute myocardial infarction was most frequent during July and August and least frequent during the winter months. Previous reports from northern cities concerning the seasonal variation in acute myocardial infarction indicated the incidence is lowest in the summer months and highest in the winter months. Greater frequency during the winter months has been variously ascribed to (1) the increased frequency of respiratory infection, (2) an increase in body metabolism in the colder months, and (3) the effect of vasomotor reflexes caused by cold weather. The demonstration that the greatest number of such cases in Dallas have their onset in the hot summer months suggests that other factors are probably operative here. It appears probable that the physiological adjustment that must be made to preserve a constant body temperature exerts a considerable strain on the organism and may act as an important precipitating factor of acute myocardial infarction. The humidity is relatively moderate in the Dallas area and does not appear to be an important stress factor in this region. Mild heat exhaustion is a comparatively frequent occurrence in Dallas.

Phenobarbital Sensitivity Syndrome.—The occurrence is reported of a syndrome of erythematous rash, high fever, mental confusion, and toxic damage of parenchymatous organs in two men and one woman following administration of therapeutic amounts of phenobarbital sodium. One man and the woman died, while the other man has recovered. Necropsy in the case of the woman revealed small hemorrhages in the tracheobronchial tree, skin, kidneys, stomach, and oral cavity. The viscera were jaundiced, the liver was fatty, and the spleen was congested. On microscopic examination the liver showed a severe diffuse destructive process. Cells in all stages of necrosis were observed. The similarity between the authors' three cases and others reported in the literature was remarkable. Similar reactions to other barbiturates are extremely rare. It may be of some significance that phenobarbital (phenylethyl barbituric acid) is the only commonly used barbiturate containing a phenyl group. Conceivably, some abnormality in the metabolism of phenobarbital in sensitive persons might liberate a phenol derivative capable of producing a diffuse cellular damage in the parenchymatous organs. The questionable response of the woman to *p*-aminobenzoic acid and of the surviving man to tripelennamine (Pyribenzamine) would seem neither to establish nor to refute an allergic hypothesis. The surviving patient seemed to improve when he was given 1 gm. of procaine hydrochloride intravenously in 1,000 cc. of isotonic sodium chloride solution. Procaine was given on the fourth and fifth hospital day, at which time his fever began to fall by lysis, his rash to fade and the mental symptoms to regress. Three months later temperature elevation, rash and swollen painful joints again developed, and he was again given tripelennamine for two weeks. Administration of the drug was then discontinued, and the patient began to improve and was well one week later. As an experiment he was again given tripelennamine; after three doses, his fever and rash recurred but promptly disappeared when the drug was omitted. The developed sensitivity to tripelennamine with features similar to the original phenobarbital reaction would suggest that the original response was allergic in character. Similar reactions to phenobarbital may be expected because of the wide clinical use of this drug. Management should entail careful attention to the hepatic function. In view of the bleeding tendency observed in these patients, hypoprothrombinemia may be a factor and, if present, vitamin K_1 oxide or a similar substance may be of value. Intravenous administration of procaine hydrochloride is indicated. Corticotropin and cortisone may be tried.

Use of Nisentil in 1,000 Obstetrical Cases.—Nisentil (1,3-dimethyl-4-phenyl-4-4-propionoxy-piperidine) hydrochloride, which has chemical structure similar to that of meperidine (Demerol), was used by Kane in 1,000 obstetrical cases. It was found to give satisfactory analgesia in 98.1% of the deliveries.

Nisentil (60 mg.) in combination with scopolamine (1/150 grain) injected subcutaneously was found to give the best results. Administration of Nisentil may be repeated safely in proportion to subjective response. Side-effects from the drug were observed in eight mothers (0.8%), who complained of dizziness. There was no vomiting. Fetal respiratory depression was present in 4.9% of the cases. The over-all fetal mortality was 1.7%, but none of these deaths was attributable to use of Nisentil. Nisentil as a valuable drug for obstetric analgesia because of its rapid onset of action, relatively short period of maximal effect, and its minimal depression of respiration in the infant.

Scleral Resection for Retinal Detachment.—Pischel and Kronfeld point out that in the ordinary case of recent retinal detachment, the break-closing operation is highly effective. However, in a number of eyes with fresh idiopathic detachments and in a larger number of eyes in which one or several diathermy operations have been performed without success, the mechanical conditions are such that closure of all existing breaks by electrocoagulation of the underlying choroid, followed by drainage of the subretinal fluid, is either inapplicable or inadequate. Lindner realized in 1933 that in cases of detachments with fixed retinal folds and strands adherent to the retina in the vitreous and in cases in which the retina assumed a funnel shape at a very early stage, the principle embodied in the globe-shortening operation would be applicable. Lindner developed scleral resection from a rather crude operation to a reasonably safe procedure. He epitomized the principle of the globe-shortening operation as a race between the shrinking vitreous and the decrease in the size of the eye. Pischel and Kronfeld review their experiences with scleral resections in 150 eyes with retinal detachment. There were 46 cures, 14 improvements, and 90 failures. In the cases in which cure was obtained, it was possible in almost every instance to determine the outstanding pathological feature which was alleviated or corrected by the scleral resection. In many of the failures, the visibility was not good enough or the fundus picture clear enough to correlate the failure of the operation with any specific feature of the pathogenetic mechanism. Among the patients in whom treatment failed was a small group with advanced diabetic retinopathy with bizarre detachments of the retina and strands in the vitreous that could be readily seen with the slitlamp and often with the ophthalmoscope. The other usual features of diabetic retinopathy were also present, such as masses of hard exudate, retinal hemorrhages, and small aneurysms. Scleral resection was done in the region where it seemed to have the best chance of slacking the tension on the vitreous strands. It was undertaken with the hope that the progress of the disease might be temporarily halted, but the results were poor. New and large retinal or vitreous hemorrhages developed immediately after the operation, and the eyes were either worse or no better than before the intervention. The authors conclude that the scleral resection operation is effective in certain specific situations.

Crush Syndrome in Ophthalmology.—During World War II in some persons who had been covered by debris from buildings during air raids and appeared to be uninjured at the time renal symptoms known as "crush" syndrome later developed. Trueta and others compressed the extremities of experimental animals by elastic tourniquets and observed that, several hours after the tourniquet had been removed, the distal part of the femoral artery remained contracted, that the renal arteries were also spastically contracted, and that the renal cortex appeared to be ischemic. Alterations of the retina are also found as belated sequelae of injury, such as traumatic edema and traumatic angiopathy. Traumatic edema may follow contusions of the globe and is associated with a distinct, although transitory, opacity of the retina. Traumatic retinal angiopathy, including retinitis stellata, usually follows injury of the skull and chest. Considering Trueta's explanation that crushing injuries may be followed by distant neurovascular effects, the cause of the fundus changes becomes more apparent. The subjects of the present study were persons with apoplexy who had eyeground hemorrhages. Autopsies were performed within 24 hours after death. Weinstein regards cerebral hemorrhages resulting from a crushing injury to the brain and the retinal hemorrhages as the distant neurovascular effect. He attempts to explain such angiospastic-atonic conditions as Berlin's retinal edema, Purtscher's retinal lesions, and traumatic glaucoma by applying to the ocular lesions the deductions made by Trueta on the crush syndrome, when he described renal cortical ischemia as a distant effect of trauma. The analogy between Trueta's renal and Weinstein's ocular findings was verified by autopsy in four cases of apoplexy and by correlation of the postmortem findings with eyeground findings before death.

Ocular Complications in Brucellosis.—Brucellosis like syphilis and tuberculosis may produce manifestations in any system of the human organism. The authors direct attention of ophthalmologists to brucellosis as a cause of eye disease by presenting the results of a survey by the department of medical research on brucellosis of the General Hospital of Mexico City, and the antibrucellar center of Torreón, Coahuila, Mexico. Most published papers on the ocular complications of brucellosis failed to establish the diagnosis of the systemic infection with absolute certainty. Brucella organisms were seldom isolated from suspected cases, and not rarely the diagnosis of the general condition was based on the existence of a positive cutaneous allergy, which is only proof of a previous brucellar infection. The authors thought that investigation of the incidence of ophthalmopathy in patients with established brucellosis is a more adequate method of studying the ocular aspects of the disease. Their studies were made on 413 patients. A positive blood culture was obtained in 223, an agglutination higher than 1:160 (Wright) was present in 293, and a positive cutaneous allergy test was obtained from 348. Ophthalmopathy was observed in 12 and neuro-ophthalmologic disorders in 48, a total of 60 or 14.25%. The relationship between the ophthalmic disturbance and brucellosis seemed undoubted in 54, probable in 5, and questionable in 1 case. In Mexico, where the human infection is almost always due to B. melitensis, purely ophthalmologic manifestations of brucellosis are rarely observed, while the disorders of the visual neurological system (especially the optic nerve) are observed rather frequently. Brucellosis may involve any ocular structure, producing atypical pictures. Involvement of the optic nerve is quite characteristic; there is perineuritis with slight changes in the visual fields and frequently unaffected central vision; normal fundus (retrobulbar optic neuritis); and congestion of the disk or true papillitis. The changes frequently regress to normal, but may lead in a few instances to a simple or postneuritic atrophy of the disk. In any endemic area, as that of Mexico, any person with the previously mentioned optic nerve disorders should be studied for the presence of brucellosis.

Premenstrual Tension.—About 40% of women at some time suffer from premenstrual tension. When severe, the symptoms may include depression, irritability, temper outbursts, easy fatigability, sleeplessness, change in energy level, altered sex drive, backache, headache, nausea, vomiting, abdominal fullness, weight gain, aching of thighs, tenderness and swelling of breasts, and pedal edema. Psychiatrists refer to the condition as "menstrual psychosis," because depressive psychoses have been known to be precipitated or aggravated at this period in the hormonal cycle. Attempts have been made to explain the syndrome as an endocrinological imbalance, particularly of the estrogen-progesterone level. Therapy based on this theory, however, has been unrewarding. Symptoms of premenstrual tension cannot be accounted for on the basis of generalized water retention alone. Little attention has been directed to the psychodynamic aspects of premenstrual tension. It was felt that some correlations might be established by simultaneous physiologic and psychiatric observations on a group of persons with premenstrual tension and on a group of controls. A questionnaire study was made of 127 student nurses, ranging in age from 18 to 35. From this group 10 subjects were selected for careful study. Five were controls and the other five had symptoms of premenstrual tension. The study covered at least two menstrual cycles. Pelvic examination and basal metabolic rate determinations were done. Vaginal smears were made daily during the first month of study and for three to five days during the second month to include the estimated day of ovulation. These smears were obtained by the subjects themselves. Urinary gonadotropin titers were measured for three days at the time of ovulation. Eight interviews, each of approximately one hour's duration, were scheduled so that the subjects were seen in various phases of the menstrual cycle. Electroencephalograms were recorded in the 24 hours after bleeding, at the time of ovulation (within 24 hours), and in the premenstrual period (3 days and 1 day before bleeding). There was no indication that the behavioral manifestations of premenstrual tension reflect alterations in the cerebral neurophysiology. Endocrine activity was within normal limits in all subjects, with no demonstrable distinction between subjects with premenstrual tension and controls. There was no evidence to substantiate the theory of psychogenic etiology for premenstrual tension; however, there were some differences in the behavior other than the premenstrual manifestations differentiating the two groups. The subjects with premenstrual tension showed greater emotional instability throughout their cycles, and in general they were less assertive.

Mass Immunization of Dogs Against Rabies.—Fredrickson and his associates state that since 1921 rabies has become a complex public health problem in St. Louis. Six rabies epizootic outbreaks have occurred during that time, and each outbreak has been more serious and of longer duration than the previous one. Since 1936 there have been 1,677 reported cases of animal rabies, almost all in dogs. All cases of rabies referred to in this report were confirmed by laboratory examination. A sudden increase in rabies late in 1950 led to a quarantine proclamation requiring every dog to be restrained by a leash when on the public streets. Regulations for redemption of dogs from the city pound required that all dogs be released to a veterinarian for a prophylactic rabies inoculation. Despite these regulations, the number of rabid dogs continued to increase. The greatest number of rabid dogs came from slum districts. A public health veterinarian made the following recommendations: (1) mass immunization clinics; (2) an educational program for dog owners; (3) turning over of the stray dog control program to the health division; and (4) immediate action for an ordinance requiring annual vaccination for all dogs. Immediate steps were taken to organize the rabies inoculation campaign. Eighteen clinics were opened on May 23 and were operated from 4 to 8 p.m. for seven days through June 1; 38,000 dogs were vaccinated at these clinics. Approximately 20,000 additional dogs were vaccinated in the private offices of veterinarians. This intensified vaccination program, in which a high percentage of the canine population was inoculated in a short period of time, proved of far greater value than sporadic inoculation of small numbers of dogs over an extended period in the same metropolitan area.

Laboratory Diagnosis of Leptospirosis.—Although the demand for leptospiral diagnostic laboratory services is constantly increasing, existing facilities are inadequate. Studies conducted on leptospirosis in Puerto Rico afforded an opportunity to evaluate laboratory techniques and to determine their suitability for employment as routine diagnostic laboratory procedures. Seventy-nine bacteriologically proved human cases of acute leptospirosis comprise the series on which this report is based. The authors believe that laboratory confirmation of the diagnosis of acute leptospirosis may be most readily and reliably made by direct blood culture and serologic examination by complement fixation employing sonic-vibrated leptospiral antigens. Blood cultures should be made during the initial febrile stage of the illness. Serial serum specimens, the first obtained early in the disease, are essential for demonstration of the diagnostic rise in antibody level. Both procedures *recommended are within the capabilities of the ordinary diagnostic* laboratory, provided diagnostic complement-fixing antigens are available. Identification of leptospiral strains requires the employment of antibody absorption techniques and is best accomplished at a leptospiral reference laboratory.

Visualization of Common Duct During Cholecystography.—Recent experience *with evacuation* studies during cholecystography confirmed in some instances by operative cholangiography has permitted the diagnosis to be made preoperatively, thereby enabling the physician to plan the necessary medical or surgical therapy. Cholecystography should consist of multiple films taken at approximately 8 minute intervals during the first 30 minutes following the fatty meal. Additional films at varying time intervals, as determined by the roentgenologist, should be taken if there is evidence of abnormal biliary function. In conjunction with this technique, prostigmine given just prior to the fatty meal, aids in the visualization of the common duct by its direct constrictive action on the smooth muscle of the sphincter of Oddi. Only in this manner can such findings as dysfunction or fibrosis of the sphincter of Oddi or compression of the common duct by pancreatitis be diagnosed by cholecystography.

Sympathectomy in Occlusive Arterial Disease.—Earlier reports (beginning in 1935) on sympathectomy in peripheral vascular sclerosis were concerned chiefly with patients with advanced disease. The purpose of the operation was to promote healing of an amputation stump or to arrest progressive tissue necrosis. Recently surgeons have emphasized the value of earlier operation for these patients before necrosis of any great extent occurred, either to prolong the usefulness of the limb or in the treatment of intermittent claudication. Knox and Parsons present observations on 32 patients with various stages of peripheral arteriosclerosis treated by lumbar sympathectomy in the five year period ending in December, 1951. There were no operative deaths. Despite the use of a variety of diagnostic and prognostic tests, there was no infallible procedure or combination of procedures that accurately predicted the result of sympathectomy. Arteriography and plethysmography were the most helpful. Sympathectomy is of value in the majority of patients with symptomatic peripheral sclerosis, particularly in persons in whom tests indicate some residual vasomotor activity. The poor results in patients with tissue necrosis were *emphasized, not to condemn the operation in this group* but to urge earlier intervention. Earlier intervention is particularly desirable in patients with claudication as their main complaint, since it is in this group that best results were obtained.

Fatal Reaction Following Intravenous Administration of Dextrose Solution.—An 18-year-old woman had had incapacitating asthmatic attacks for the previous four summers. She was hospitalized because of abdominal pain for two days and no bowel movements for one week. Abdominal exploration and appendectomy was done on the fourth day. On the afternoon of the day of operation, the patient was receiving 2,000 cc. of fluid intravenously. The second 1,000 cc. of 10% dextrose had just been added when she had a chill. Her *temperature rose immediately to 106 F, with* a blood pressure of 60/0. The remaining portion of the intravenous fluid was sent to the laboratory for examination. On the following day a medical consultant made a diagnosis of probable streptococcic septicemia, with acute adrenal insufficiency and bilateral bronchopneumonia. The patient's condition did not improve, and on the morning of the third postoperative day the blood pressure gradually dropped in spite of transfusion. The temperature rose to 107 F, oliguria developed, and the pulse disappeared. The patient died 64 hours after the administration of the suspected intravenous fluid. Culture of heart blood and of the spleen grew Aerobacter aerogenes. The most important pathological changes were those in the lungs and consisted of an allergic type of bronchiolitis and bronchitis with secondary widespread atelectasis. There were also widespread focal areas of hemorrhage and foci of infarction of the myocardium and the liver, probably best explained on the basis of anoxia. The kidneys showed early lower nephron nephrosis. The mechanism of death was thought to be respiratory failure due to anoxia secondary to the allergic bronchitis and bronchiolitis, with resultant widespread atelectasis. The authors assume that the organism A. aerogenes was in the bottle of the solution before being given to the patient and that it was responsible for the generalized anaphylactic picture.

Effect of Streptomycin on Bacterial Resistance to Isoniazid.—Preliminary bacteriological results are presented from a large-scale clinical trial on 150 tuberculous patients treated for 28 weeks with isoniazid alone, isoniazid combined with streptomycin, and streptomycin combined with *p*-aminosalicylic acid. The sputum of a high proportion of the patients became bacteriologically negative with all three treatment regimens, isoniazid with streptomycin giving the highest number and isoniazid alone the least. The absolute percentage of patients whose sputum became negative apparently depended on such factors as the severity of the disease and previous antimicrobial treatment. The presence of cavities tends to reduce the chances of a patient's having negative sputum after a course of isoniazid therapy. Almost all cultures of sputum that was still positive after 28 weeks of treatment showed some resistance to isoniazid when it had been the only drug administered; nearly all showed resistance of some degree to both streptomycin and isoniazid when both were used; and all cultures were at least moderately resistant to streptomycin when both streptomycin and *p*-aminosalicylic acid were used. Thus, all cultures positive for Mycobacterium tuberculosis obtained after 28 weeks of treatment with any of these drug combinations contained tubercle bacilli that were to some degree more resistant to the particular drugs (excluding *p*-aminosalicylic acid) to which they had been exposed. In another and more critical respect the three regimens proved to be unequal. Tubercle bacilli were detected after 28 weeks of treatment in the cultures of one-half of the isoniazid-treated patients, in one-third of the patients treated with streptomycin and *p*-aminosalicylic acid and in one-fourth of the patients treated with streptomycin and isoniazid. Thus, while all positive cultures of patients treated with any of the three regimens contained organisms resistant to the drugs given, substantially fewer patients continued to have cultures positive for tubercle bacilli after treatment with the combination of streptomycin and isoniazid. The regimen that offers the greatest probability of the sputums becoming negative provides also almost certain development of resistance to both streptomycin and isoniazid if the sputum has not become negative by the end of the course of therapy. The other two regimens that offer less chance of sputum conversion will produce bacilli resistant to only one of the potent drugs, leaving either streptomycin or isoniazid for subsequent use.

Laryngeal Swabs for Culture of Mycobacterium Tuberculosis.—Two laryngeal swabs were taken concomitantly with an aspiration of gastric contents in 1,418 patients in chest clinics operated by the Bureau of Tuberculosis of the New York City Health Department. Cultures for Mycobacterium tuberculosis were prepared 24 hours later. Of the 1,418 patients, 207 (almost 15%) had cultures positive for Myco. tuberculosis from the gastric contents, from the laryngeal swabs, or from both sources. Of these, 187 (90%) showed growth from the gastric contents, and 135 (65%) from the swabs. Thus, two laryngeal swabs taken at the same time proved to be approximately 72% as effective as a single gastric aspiration for the detection of Myco. tuberculosis. In spite of the conveniences of the swab technique in the clinic, gastric aspiration remains the method of choice for the detection of Myco. tuberculosis in patients unable to produce an adequate sputum specimen. The laryngeal swab technique is worthy of adoption as an additional diagnostic tool for the bacteriological diagnosis of tuberculosis in ambulatory patients to be used when gastric aspiration cannot be readily performed.

Intravenous Use of Thiophanium Derivative.—Twenty-five patients with moderate hypertension or normal blood pressure were given a thiophanium derivative just before operation to bring about controlled hypotension. The drug used was Arfonad (d-3,4[1',3'-dibenzyl-2'-keto-imidazolido]-1,2 trimethylene thiophanium d-camphor sulfonate). Intravenous administration of a solution containing 0.25 to 1 mg. of Arfonad per cubic centimeter was started at a rate of 0.5 to 4 mg. per minute, with the patient placed in the supine position in a 5 degree head-up position. The patient's blood pressure was quickly reduced and the rate of administration of Arfonad was then lowered to 0.25 to 0.5 mg. per minute. The anesthetic agents used were ether, cyclopropane, nitrous oxide, *thiopental sodium, or decamethonium (Syncurine) bromide.* Arfonad apparently was not incompatible with any of these anesthetic agents. The same flexible, graded, and readily reversible lowering of the arterial blood pressure was obtained in these anesthetized patients who were undergoing operations as had been previously obtained in unanesthetized patients. Middle-aged, moderately hypertensive patients were definitely more susceptible to the vasodepressor action of Arfonad than the younger normotensive patients. Administration of hexamethonium chloride in addition to Arfonad had little effect in lowering the blood pressure that was not decreased with Arfonad alone. The graded, flexible vasodepressor response to the intravenous administration of Arfonad makes it possible to select and maintain an ideal hypotensive level by varying the flow rate. The hypotensive state is associated with a disturbance in the heat-regulating mechanism because of the prolonged peripheral vasodilitation. Therefore, a state of hypothermia is to be expected at the conclusion of the operation. Once the state of hypotension has been induced, very little additional anesthetic agent is required. It was the impression of the operating surgeons that the tendency to bleed and the actual loss of blood were less than would have occurred had *the arterial pressure remained normal. Postoperative hemorrhage,* such as might have been expected from smaller vessels that had been severed but had not been observed because of the hypotension, was not encountered. Six illustrative cases are described in detail. Arfonad is a useful agent for the production of graded and reversible hypotension with ether, cyclopropane, nitrous oxide, and thiopental anesthesia alone or in combination. The need to predict the depressor response of any given patient to a given dose of a drug has been modified by the continuous intravenous use of this agent, as the depressor effect of Arfonad is transient.

Toxicity of Streptomycin and Dihydrostreptomycin for Eighth Nerve.—*Heck and associates* in 1951 compared the relative toxicity of streptomycin and dihydrostreptomycin in a controlled experiment. The primary objective was to note the relative therapeutic effects on pulmonary tuberculosis; as a corollary, the toxicity of both drugs was checked. Patients considered suitable for chemotherapy were alternately assigned to one of two groups. One group received drug "A" and the other drug "B." One drug was streptomycin sulfate and the other dihydrostreptomycin sulfate. Which was "A" and which was "B" was not known to the physicians in charge. Each patient received 1 gm. daily of one of the drugs for a total of 120 days. Each drug was given to 34 patients. Dihydrostreptomycin was more consistently effective than streptomycin. Studies on ototoxicity revealed that only 2 of 34 patients who received dihydrostreptomycin had vestibular disturbances; they were subjective only, consisting of transient minimal vertigo. Auditory disturbances, however, were evident in five patients. Six of the 34 patients receiving streptomycin had vestibular disturbances. No auditory disturbances occurred in this group. The neurotoxic effects on the eighth nerve by streptomycin were predominantly upon the vestibular apparatus and of dihydrostreptomycin on the auditory apparatus. It may be postulated that the vestibular dysfunction is reversible because the apparatus is an older, more primitive mechanism. The newer, exceedingly delicate auditory apparatus, on the contrary, has little recuperative ability.

Scarlet Fever Treated Orally with New Salt of Penicillin.—An *oral suspension* of *N,N'dibenzylethylenediamine* dipenicillin G (Bicillin) was used in the treatment of 27 children with scarlet fever and 9 children and 2 adults with other infections of the throat and nasopharynx. The scarlet fever patients received the medication in average doses of 7,000 or 13,000 units per kilogram of body weight every six or eight hours. The drug was given on an empty stomach one hour before breakfast. To obtain comparative blood levels, each of 24 patients with scarlet fever received one dose with breakfast. Blood samples were withdrawn at varying intervals after medication to determine the blood concentration of penicillin. The average penicillin blood level rose more rapidly and to a higher level when the drug was administered on an empty stomach, but the blood level was more sustained when given with a meal. The differences were slight. The *drug may* be given without regard to the meals. All patients recovered rapidly and without complications or sequelae. The clinical response was as good in those showing blood levels of less than 0.025 unit per milliliter as in those showing higher penicillin plasma concentrations. There was no evidence of kidney damage nor of rheumatic fever as a result of streptococcic infection; no suppurative sequelae nor side-effects occurred. No serious or lasting cardiac abnormalities were demonstrated by electrocardiograms. The oral suspension is palatable, was accepted without difficulty by all patients in both groups, and was well tolerated.

Pathogenic Potentialities of Domestic Water Fluoridation.—In 1930 it was established by biochemists in Arizona that fluorine in the water of the regions where "mottled" teeth are prevalent was responsible for this condition. The discovery that the incidence of tooth decay was also low in regions with relatively high fluorine content in the drinking water quickly led to the assumption that the natural fluorine content of the local water supply was the beneficial agent. Little attention was given to the possible favorable effects of sunlight, to the superior mineral content of foods, or to the fact that these regions produced citrus fruit with its high content of vitamin C. The precipitous conclusion regarding the relation of fluorine to dental health quickly led to agitation for fluoridation of domestic water supplies, with the result that some 20 million Americans are compelled to partake of this medicated beverage irrespective of its possible long-term deleterious effects. The author directs attention to the strong affinity of fluorosis for calcium, which makes it unite with the calcium of teeth and bones. The ingestion of vegetable and animal food from areas with high fluorine concentration has resulted in the cumulative deposition of this element in the bones and teeth of man and animals. Subjects who have been using naturally fluoridated water for several decades have considerable periodontal disease, with enlargement of the roots and narrowing or closure of root canals and pulp chambers; premature aging of the tooth structure is promoted and extraction is made very difficult, with tendencies to root fracture. Many of these patients have severe gingivitis and pyorrhea. Workers in cryolite mining, who inhale fluorine dust, exhibit not only the aforementioned dental defects but also osteophyte formations on bones, osteosclerosis, calcification of tendons, "poker backs," and fixation of the thoracic wall. These same effects have been noted in parts of Africa and India where the natives have long been using naturally fluoridated water. The author offers suggestions for protection against the toxic effects of fluorine for those who fiind themselves unwilling subjects of this experiment in mass medication. 1. He recommends the daily ingestion of small doses (5 to 10 grains [0.3 to 0.6 gm.]) of certain innocuous calcium salts; calcium ascorbate is particularly valuable, since it also releases vitamin C. 2. An optimal intake of foods rich in calcium is desirable, such as milk products and green salad vegetables. 3. An optimal intake of citrus fruits will provide natural vitamin C to help counteract the toxic fluoride.

Reduction of Blood Cholesterol in Man.—Cholesterol is regularly found in human atherosclerotic lesions, and many manifestations of disease are caused by the presence of cholesterol in the vessel wall. A plant sterol mixture that contains 75 to 80% of sitosterols was given a trial as anticholesteremic agent in 26 healthy persons. The daily intake was 5 gm., divided into two doses, or 7 gm. or 10 gm. divided into three roughly equal doses taken with the meals for from eight days to eight months. All persons were on their usual diet. No restriction of intake of cholesterol and fats was attempted. Results showed that there are individual variations in the response to sitosterol. In some persons the daily dose and the total dose of sitosterol required to lower the blood cholesterol level may be twice the dose required in other persons with comparable initial levels. The response of free and ester cholesterol was almost always the same and the percentage of free to total cholesterol varied only slightly. No differences were seen in persons of different age or between men and women. On daily doses of 5, 7, or 10 gm. of sitosterol the minimum blood cholesterol level was reached within 7 to 14 days. Further decreases after this period were slight, even when 10 gm. were taken for two months. The higher the original blood cholesterol level the easier it was to depress it. Blood cholesterol levels below 200 mg. per 100 cc. could not be influenced. The more rapid and the more complete the depression of total free and ester cholesterol levels were, the more rapid was the return of these levels to the original height after the cessation of sitosterol therapy. In some persons, the return required 14 days and in others as long as 40 days. The administration of sitosterol appears to be a simple way to lower the blood cholesterol level. The author's experiments verified that sitosterol is not resorbed by man and that its oral intake does not interfere with health or with the metabolism of any foodstuff other than cholesterol. Ingestion of sitosterol in proper amounts prevents intestinal resorption of cholesterol. This results in lowering of blood cholesterols to the basal endogenous level. Continuous administration of sitosterol is required for maintenance of the basal blood cholesterol level.

Treatment of Ulcerative Colitis.—Ileostomies with simultaneous subtotal colectomies (removal of the colon down to the lowest part of the sigmoid that can be exteriorized) were performed on 15 patients with acute toxic ulcerative colitis. The two patients who died were moribund at the time of operation. The mortality rate was one-fourth of that following ileostomy alone or conservative treatment. Subtotal colectomies with simultaneous ileostomies were performed in 35 patients with chronic ulcerative colitis with no deaths. There were no deaths following the removal of the rectal stump in all of these patients. Indications for subtotal colectomy with simultaneous ileostomy in ulcerative colitis included a long-continued ulcerative process or pseudopolypoid change. In such cases the colon should be removed to prevent the development of cancer, and the risk of colectomy is much less than that of cancer. Another indication is systemic manifestations of the disease, such as arthritis or pyoderma gangrenosum. In these cases the colon should be removed promptly before irreversible damage is done or before the patient's general condition becomes so poor that life is endangered. In acute toxic ulcerative colitis the colon should be removed as soon as possible because the risk of the disease is high and colectomy is the most effective means of preventing its fatal complications. In any case of acute toxic ulcerative colitis in which the colon is distended, perforation is impending and a fatal termination is apt to ensue if an emergency colectomy is not performed. Although medical treatment and a trial with steroid therapy may have its place in the treatment of many of the mild or chronic manifestations of the disease, acute toxic ulcerative colitis with distention of the colon is a surgical emergency and should be treated by immediate colectomy.

Allergic Regional Enteritis.—Regional enteritis due to food allergy is reported in three women, aged 41, 30 and 49 respectively. That the regional enteritis in the first patient was due to food allergy was shown by the rapid relief of all symptoms and continued control for five years with a milk-free diet. The abdominal pain, cramping, and diarrhea reappeared in one day with the reintroduction of milk. This milk allergy was not indicated by skin testing or leukopenic index. The diagnosis originally was made by history and x-ray findings, and was confirmed by microscopic examination of a surgically removed portion of the inflamed ileum. In the second patient, the correlation of relief and recurrences with elimination or addition of milk, egg, and fruits indicated food allergy as the cause of the regional enteritis. Breaks in the diet caused a recurrence of symptoms. A new physician placed her on a soft, general diet. Increasing symptoms with anorexia and finally obstruction of the terminal ileum led to the resection of the involved bowel. For two postoperative months, with a soft, general diet containing the allergenic foods, four to six daily loose bowel movements continued. The authors believe that the recent resection of the ileum would have been avoided if the fruit and cereal-free elimination diet plus rice had been maintained. In the third patient symptoms were well controlled for 16 months on a fruit-free diet consisting of rice, tapioca, white potato, lamb, puréed carrots, squash, sugar, salt, and water. Recovery was hastened by administration of cortisone given orally in doses of 25 mg. three times daily for nine days. The evidence accumulated by Andresen and Rowe that allergy, especially to foods and pollens, is the major cause of chronic ulcerative colitis necessitates the study and treatment of the role of allergy in regional enteritis. The localization, spreading tendency, remissions and recurrences, fever, occasional inherited predisposition, and relief obtained with x-ray therapy and cortisone can be explained from the allergic viewpoint.

Tuberculosis in Leprosy Patients.—Tuberculosis is universally a common and serious complication in leprosy patients. Of 607 patients who died in the leprosarium at Carville, La., among 1,512 admitted prior to July 1, 1950, 141 had moderately or far-advanced active tuberculosis at the time of death, making tuberculosis a primary or contributary cause in 23% of all deaths. Another 16 patients had minimal active tuberculosis and 13 had arrested tuberculosis. The records of patients admitted to the Carville leprosarium between 1922 and 1950 were examined for evidence of active or arrested tuberculosis. Sulfone therapy improved the leprosy in these patients over a period of several years, with a marked reduction in deaths from all causes. The reduction in deaths of patients with tuberculosis has been even greater than in deaths of patients without tuberculosis. There has been an increase in the age at which tuberculous patients died since sulfone therapy has been instituted. Patients with tuberculosis and leprosy have had their tuberculosis arrested with sulfone treatment alone, but a combination of a sulfone and streptomycin appears to be more effective than a sulfone alone.

Effects of Hormones on Nitrogen Balance in Elderly Patients.—Kountz and associates present observations on the nitrogen balance and clinical status of seven elderly persons with constant protein intake during the administration of a number of hormonal substances. Thyroid substance (¼ to 1 grain [16 to 64 mg.] per day) caused little change in nitrogen balance and slight improvement in the clinical state of these persons. Insulin (5 or 10 units of protamine zinc insulin per day) caused some increase in nitrogen retention, an increase in appetite, and changes in glucose tolerance curves. Oxytetracycline (Terramycin) caused no significant changes in nitrogen balance or clinical status. Cortisone (100 mg. per day) and corticotropin (15 to 60 mg. per day) both caused a marked increase in nitrogen excretion during the first days of administration, but there was a return to a positive nitrogen balance during continued administration of either drug. There was some edema and water retention in all persons who received cortisone and corticotropin. With both drugs there was an initial increased feeling of well-being. Irritability and mental depression developed after cessation of treatment.

Experimental Renal Hypertension Treated with Renin—The three principal hypotheses of the cause of renal hypertension are alteration in the renin-angiotonin (hypertensin) mechanism, decreased secretion of renal blood pressure regulating hormone, and increased formation of pressor amines by the kidney. Additional evidence is needed not only to clarify the physiological mechanisms involved in experimental renal hypertension but also because the many similarities between experimental renal hypertension and essential hypertension suggest the possibility of a partial common pathogenesis. As one approach to the problem, this research group reported the production of antirenin, an antibody to heterologous renins. Some interspecies reactions were observed, including neutralization in a dog of the pressor effect of dog renin by antirenin to hog renin. They also reported reductions in the blood pressures of dogs with renal hypertension with repeated injections of crude hog renin; probably the mechanism of these reductions involves an immune (antihormone) response to the heterologous hog renin, inasmuch as dog renin and heat-inactivated hog renin were shown to have no effect on the blood pressure of other dogs with renal hypertension. Now the authors present evidence that chronic experimental renal hypertension in dogs can be successfully treated or prevented by the use of crude and semipurified hog renins. These therapeutic and prophylactic effects are well-correlated with the antirenin titer. This evidence for antirenin (or an antibody to a protein closely related to renin) as the mechanism of the antihypertensive effects of hog renins supports the concept of the primary role of renin (or some closely related protein) in the pathogenesis of experimental renal hypertension. Hog renal medulla contains a factor that interferes with the antihypertensive effects of hog renin in experimental renal hypertension in the dog by a mechanism still unknown. Renotoxic and renal protective factors have been found to occur in fractions of renal extracts, as demonstrated by an increase and/or decrease in the incidence of uremia after constriction of the renal arteries. After further preliminary experiments in animals, the possible pathogenetic role of the kidney in essential hypertension will be studied by passive immunization of patients with purified antirenin against human renin.

Postgraduate Medicine and Undergraduate Medical Education. —The author presents comments, analyses, and experiences of several hundred practicing physicians. Many stated that they really began to learn medicine after they started their internship or entered active practice. Graduation from medical school is basically "commencement" insofar as the acquisition of medical knowledge is concerned, but this concept is somewhat unfair to undergraduate medical instruction, and raises questions such as is the curriculum designed to give the medical student a broad basis for entering medical practice? In a sense, undergraduate medical education occupies a position comparable to liberal arts education—an educational offering that is not purely technical nor complete in itself but is designed to equip the candidate to acquire and to extend his knowledge in fields in which he may be interested. If postgraduate medical education will record the present and future trends of medical practice, as well as examine the abilities of graduating physicians to meet these trends, it will render useful service. One of the deficiencies in the undergraduate medical curriculum is the insufficient training in the common, minor ailments. Inadequate training in the care of the chronically ill, in bedside diagnosis, in therapeutics, in fields like anesthesiology, diagnostic roentgenology, dermatology, psychiatry, and neurology were also frequently mentioned as deficiencies in medical training. There is also often a lack of comprehension of social, economic, governmental, and other factors influencing the nature of medical practice. The modern community hospital has become entrenched in the framework of medical care, and comprehension of the various facets of hospital operation should be known to all physicians. Many practicing physicians commented on the inability to express the causes and prevention of disease to lay patients in terms that are readily comprehensible; misunderstanding or lack of understanding of medical ethics; insufficient training in maintaining vital statistics; inadequate comprehension of public health and how the local public health agencies may contribute to private practice; lack of training in how to set up an office, arrange the doctor's bag, and organize one's time to conform to the demands placed on the physician; and lack of knowledge of various postgraduate medical opportunities.

Effects of Methantheline (Banthine) on Vesical Function.—The effects of methantheline (Banthine) on the function of the urinary bladder were investigated in 74 patients with various bladder disorders and in 17 normal subjects. Methantheline was given by mouth in single doses of 100 mg. or 150 mg. or in repeated doses of 50 to 100 mg. four times a day over a period of several weeks. Observations were made following intramuscular injections of 25 or 50 mg. Control observations were made with a bitter placebo of identical appearance, or by sterile hypodermic injection, as well as without the administration of any agent. The tone and capacity of the bladder were investigated with an ordinary water cystometer. An isotonic sodium chloride solution was introduced into the empty bladder slowly to avoid rapid abnormal distention of the bladder and consequent reflex contraction. The time of appearance of the desire to void and of the presence of pain were noted. Over 500 cystometric determinations were made. Usually there followed a decrease in bladder tone, associated with diminished force and frequency of spontaneous contractions, and this in turn usually resulted in an increase in bladder capacity. The effect was most striking in patients with contracted bladders and bladders of small capacity. In these subjects, nocturia, diuria, and strangury could be reduced with minor side-effects of the drug. In the absence of excessively strong stimuli, methantheline has been shown to relax bladder spasms caused by parasympathetic stimulation. Methantheline is a better antagonist to furtrethonium (Furmethide) than atropine in the dosage used in these experiments.

Results of Treatment of Bladder Tumors.—Milner was struck with the lack of correlation between reports on the pathological aspects of bladder cancer from different clinics. He regards the approach suggested by Jewett and Strong and slightly modified by Marshall as most sound from the clinical as well as the pathological viewpoints. Jewett observed that deeply invading tumors of a high degree of malignancy usually are difficult to treat and have high five year survival rates. In 104 cases Marshall found that his clinical preoperative estimation as to depth of invasion into the bladder wall was correct in 81% of the cases and that most errors were in underestimating the depth of penetration. Milner made the same observation and found that adequate biopsy specimens properly taken transurethrally will give a true picture of the degree of malignancy of bladder neoplasm. He marks the selected piece of tissue for biopsy by transfixing it vertically with a common pin before sending it to the laboratory so that the pathologist can imbed it in the paraffin block in such a way as to make vertical sections. Thus he can readily see the depth of muscle invasion. This along with the cystoscopic picture and bimanual examination with the patient under anesthesia, as described by Jewett, was found quite helpful by Milner. He evaluates the results obtained in 386 patients who were operated on five or more years ago. A total of 314, or 81.3%, could be followed up to the end of the reporting period. Only 58.3% of the patients with papilloma but 86.9% of those with cancer could be followed. The records were reviewed and an attempt was made to classify each case as to depth of extension of the tumor. Both the operative description and the pathological report were of value, and 261 cases could be classified. In the classification used by Milner, stage O indicates limitation to the mucosa; stage A, to the submucosa; stage B_1, to the superficial muscle; stage B_2, to the deep muscle; stage C, to the fat; and stage D, metastases, D_1 being local and D_2 being distant metastases. The results of seven different types of operative treatments are reviewed and correlated with the stage of the tumor and the survival rate. It was found that tumors of stages O, A, B_1, and B_2 have a better survival rate when treated conservatively than when radical surgery is employed. Tumors of stages C, D_1, and D_2 are best treated by radical surgery with lymph node dissection. If it were not for the postoperative mortality and morbidity, however, some stage B_2 tumors would probably be better treated by radical removal with node dissection. The operative mortality of the cases operated on by the closed method was 0.6%. The operative mortality of the open method was 15.2%.

Toxic Psychosis Due to Isoniazid.—A physician, aged 47, was committed for institutional care because of an alleged reaction to isoniazid. The history revealed that he had had active tuberculosis several years previously. The disease had been arrested but had become reactivated twice. At the time of a new relapse in 1952 he was given isoniazid in a dose of 500 mg. daily on an ambulatory basis. He was anxious to get well and increased the dose from time to time until he was taking 950 mg. daily. Soon after he began to feel nervous and restless. He took phenobarbital with each large dose of isoniazid for about one week. When the phenobarbital failed to relieve the nervousness and restlessness, he stopped taking it, but continued taking 700 mg. of isoniazid daily. Several days prior to his hospitalization, he became confused, irritated, violent, and antagonistic. His gait was ataxic and his language abusive. He harbored delusions of persecution. There was no history of previous mental illness, either personal or familial. He drank alcohol occasionally, but denied alcohol or drug addiction. He was suspicious, apathetic, and uncooperative. He spoke irrationally and irrelevantly and had delusions of persecution. There was a slight tremor of the hands and an ataxic gait. He was given sedatives for the first two nights after admission and vitamin B_1. On the third day he became more cooperative and friendly. From then on he ate and slept well and the paranoid delusions disappeared. It is believed that this patient had a toxic psychosis due to excessive intake of isoniazid. Phenobarbital intoxication was considered unlikely. The toxic dosage producing the psychosis was estimated to be 700 to 950 mg. daily, i. e., 10 to 14 mg. per kilogram of body weight. Persons taking this drug should be hospitalized, especially when daily doses larger than 10 mg. per kilogram of body weight are to be given.

Effect of Radiocobalt (Co^{60}) Gamma Radiation on Passive Immunity.—Hale and Stoner chose radiocobalt (Co^{60}) gamma rays for the study of the effect of whole body ionizing radiation on the immunity mechanism. The radiation source was composed of 21 pieces of Co^{60}, arranged to give a uniform field at 12 in. (30 cm.) from the source. Fifty mice could be irradiated at one time. The intensity at the time of these experiments was approximately 650 rep per hour and the LD_{50} for mice 28 days of age was 750 rep per hour. The detrimental effect of Co^{60} gamma irradiation on passive immunity to pneumococcus type 3 organisms is shown in one table. Another table shows the effect of Co^{60} gamma radiation on mouse resistance to pneumococcus type 3 mixed with a tenfold excess of specific antiserum, when the mice were irradiated three days before the injection of the bacterial and antiserum mixture. It was found that the 650 rep whole body irradiation destroys the protective power given by this amount of immune serum. The radiation controls showed that no deaths were due to radiation alone. An attempt was made to decrease the Co^{60} gamma irradiation effects by injecting mouse leukocytes and whole citrated mouse blood, but the results indicated that neither the white blood cells nor the whole blood transfusions were effective in restoring the resistance enjoyed by nonirradiated animals. The authors do not feel, however, that this experiment should be considered conclusive. They believe that better methods for obtaining leukocytes may eventually make possible the restoration of the resistance of irradiated animals. Studies were made also on passive immunity to tetanus toxin and to influenza virus. It was found that whole body irradiation does not cause susceptibility to tetanus toxin when sufficient specific antitoxin was present at the time of irradiation. The active immunity to influenza type A virus is not altered by this form of irradiation.

Prophylaxis of Postoperative Thrombosis.—In 1950, 2,351 patients and, in 1951, 2,109 patients operated on for disease of the prostate, stomach, colon, rectum, gallbladder, bile ducts, kidneys, ureters, bones and joints, breast, appendix, thyroid, and hernia were given bishydroxycoumarin (Dicumarol) prophylactically from the first postoperative day. All the patients were at least 40 years old. Early ambulation was used in all cases except in cases of surgical treatment of hernia. The patients left their beds on the first postoperative day, and were given breathing exercises and passive and active movement therapy. Increased recurrence of hernia in patients operated on for uncomplicated inguinal hernia who left their beds on the first postoperative day induced the author to have these patients stay in bed for the first three postoperative days, but they received breathing exercises and passive and active movement therapy in bed. The results in the 1950 and 1951 groups were compared with those obtained in 2,051 patients between the ages of 25 and 44 who were operated on between 1946 and 1949; they were also given bishydroxycoumarin prophylactically from the first postoperative day, and early ambulation was employed. The incidence of thromboembolism was the same in the three groups of patients, i. e., 1.5 ± 0.27% in the patients treated in the earlier years, 1.5 ± 0.25% in those treated in 1950, and 1.4 ± 0.26% in 1951. Despite the fact that bishydroxycoumarin was not given to patients between the ages from 25 to 39 during 1950 and 1951, the incidence of thromboembolism during these years was not affected. It remained at the same low level as in the patients 25 or older who had been treated in the earlier years. A previous report in which the results of prophylactic treatment with bishydroxycoumarin combined with early ambulation were compared with those in patients who did not receive this type of treatment showed that the incidence of thromboembolism occurring in patients aged 45 or more had decreased by about 75% when compared with patients who had not received the prophylactic treatment. Fatal hemorrhages did not occur following bishydroxycoumarin therapy in any of the three groups.

Right Upper Quadrant Pain in Salpingitis.—About 10% of patients with salpingitis complain of lancinating upper abdominal pain localized in the area below the right costal margin. The anatomic basis of this pain is inflammatory changes in the serous membrane of the right subphrenic space. Results of necropsy studies by the author on 38 patients who died of diffuse peritonitis and of 21 patients who died of peritoneal carcinomatosis support the view that exudates and tumor cells are absorbed from the peritoneal cavity in man through the lymphatics of the diaphragm. This provides a logical explanation for the perihepatitis frequently demonstrated in cases of salpingitis and for the right upper quadrant pain associated with the inflammatory changes of the serous membrane of the subphrenic space. The same pain may also occur in other abdominal diseases associated with exudation into the peritoneal cavity. It may also occur after a laparotomy, when it is probably caused by accumulation of a postoperative peritoneal exudate below the diaphragm, and it may easily be mistaken for a pulmonary infarct. Diagnosis of pulmonary infarction should never be made on the basis of the characteristic pain alone. Pulmonary symptoms such as cyanosis and bloody sputum must also be present, and attention should be focused on a possible simultaneous occurrence of other symptoms of thromboembolism.

*Contribution to Treatment of Acute Hematogenous Osteomyelitis with Penicillin. A. Röhling.—p. 701.

Penicillin in Acute Hematogenous Osteomyelitis.—Penicillin was given to 20 patients between the ages of 1½ and 15 years, for treatment of acute hematogenous osteomyelitis. Long, tubular bones were involved in 16 patients and in 4 the pelvic bones. The interval between the onset of the disease and the institution of the treatment varied from 2 to 14 days. Doses of 8 to 12 million units of the drug were given over a period of three to four weeks. Additional treatment consisted of immobilization for six weeks to three months in six patients, wide surgical drainage of a subperiosteal abscess in 12, and sequestrectomy in 1. Staphylococcus aureus was cultured from the pus in every case. Spontaneous fractures of the involved bones near the upper metaphysis of the humerus occurred in two patients. Nineteen of the 20 patients recovered completely, while chronic osteomyelitis developed in one. A follow-up of 10 patients for two or more years revealed complete healing, no recurrence, and neither atrophy of the involved extremities nor ankylosis of the joints. Roentgenologic examination of patients treated with penicillin revealed typical changes in the morphological course of the disease. The amount of bone destruction depends on the occurrence or absence of a subperiosteal abscess. As a rule an abscess does not occur if treatment with penicillin is instituted before the third day after the onset. In the absence of a subperiosteal abscess usually only insignificant round transparencies in the diseased metaphysis are visible. A reactive periostitis is regularly associated with a shell-like layer of the periosteum. The roentgenologic picture is different if a subperiosteal abscess develops. Within four weeks after the onset of the disease widespread destruction of the bone (necrosis) due to interrupted blood supply is manifested. Rapid and intensive regeneration occurs within eight weeks. Despite the interrupted blood supply, enough penicillin reaches the necrotic bone by diffusion to reduce considerably the number of pathogenic agents and to prevent the breaking down of the bone. Little new formation of bone was observed within the first six to eight weeks of the disease, and resorptive phenomena were predominant. Penicillin is a valuable adjuvant in the treatment of acute osteomyelitis, but surgical drainage of the subperiosteal abscess and immobilization are still the principal means of treatment of suppurative osteomyelitis.

Surgical Treatment of Tuberculous Pericarditis.—Surgical correction of constrictive pericarditis has received sporadic attention. Recently there has been much discussion as to the relative merits of decorticating the various chambers of the heart. The authors present histories of four patients who were subjected to pericardiectomy. Constrictive pericarditis may follow an inflammatory process in the pericardium, but a large percentage of the cases are caused by tuberculous infection. Many lesions treated surgically after subsidence of the acute process may no longer be recognized as tuberculous. In any patient who has had a pericardial effusion the syndrome of polyserositis may develop owing to obstruction of the venous return. In the majority of cases the encasement of the left ventricle seems the most prominent feature, and a complete freeing of the ventricle is necessary for a good result. There are cases in which the right side of the heart seems to be involved as much as, if not more than, the left. The lower sternum splitting incision of Holman gives adequate exposure for pericardiectomy. Satisfactory resection of the pericardium is usually followed by rapid clinical improvement. If improvement advances very slowly, the heart has probably been incompletely freed. In three of the four reported cases, the lesions were definitely tuberculous and these three patients experienced dramatic improvement following pericardiectomy. The fourth patient had extensive pulmonary tuberculosis, but the excised pericardium did not show tuberculous foci. In the last case the heart was not completely decorticated and this is the only one that has been improved rather than apparently cured. In this case a second operation may be necessary.

Expiratory Function of Abdominal Muscles.—The muscles of the anterior and lateral abdominal wall are generally regarded as the principal expiratory muscles. By their contraction the intra-abdominal pressure is increased and the diaphragm is driven upwards; these muscles also pull the costal margin downwards. Campbell and Green used an electromyographic method for studying their activity. The activity of the external oblique and rectus abdominis muscles on the right side of 19 young men in the supine position was studied. Records were made under the following conditions: (1) during graded static expiratory effort, (2) during rebreathing from the spirometer to produce asphyxia, and (3) during performance of certain skeletal movements, i. e., lateral flexion of the trunk and raising the shoulders off the couch. It seemed to the authors that two kinds of expiratory effort may be recognized: (1) expiration occurring as a "voluntary" maneuver as in a static expiratory effort or voluntary hyperventilation or in coughing or straining; (2) expiration occurring in the course of "involuntary" natural breathing, either quiet respiration or when the breathing is stimulated by chemical agents. There is more activity of the abdominal muscles in voluntary expiration than in involuntary breathing. The level of pulmonary ventilation achieved in asphyxial hyperpnea need not involve gross fluctuations in intra-abdominal pressure that might embarrass the circulation. It seems that, when the respiratory center is stimulated maximally by aspyhxia, it can recruit only a fraction of the motor neurone pool of the abdominal muscles. In voluntary maximal breathing, however, it is possible that the respiratory center is partially or wholly by-passed by impulses from a higher brain level. Even this higher brain level cannot recruit the abdominal muscles fully, however, as is shown by the greater degree of activity of these muscles during voluntary skeletal movement.

Isoniazid in Lupus Vulgaris.—Isoniazid was given to 15 patients with lupus vulgaris. Three had not been treated previously. Five patients received the drug orally in doses of 300 mg. daily; six were given from 50 to 250 mg. of isoniazid in from 2 to 5 ml. of distilled water by weekly intradermal injections into the lesion; and four received 300 mg. of the drug daily by the oral route and 400 mg. weekly by the intradermal route. All the patients tolerated the drug well, and there was no evidence that drug resistance had developed after 30 weeks of treatment. Mild urticaria occurred in one patient who was given the drug orally, but it was not severe enough to necessitate discontinuation of the therapy. At the time of writing, the lesions of one patient were considered clinically cleared, since all signs of activity had disappeared from them. Only opacity of the lesions with slight residual scaling or discoloration was present in four patients. A moderate improvement had occurred in seven patients whose lesions were more opaque and scaling and discoloration had diminished, although a mild residual infiltration was still present. There was a slight but perceptible decrease of redness, infiltration, scaling, and translucency in the lesions of two patients. The condition of one patient remained unchanged. The authors feel that daily injection of isoniazid would be as effective as, or even more effective than, the oral administration. This method, however, cannot be extended to all patients with lupus vulgaris, since most of them are fully employed. They also suggest that isoniazid combined with calciferol may give better and quicker results than either agent alone, since isoniazid seems to have a direct action on the organisms and calciferol seems to stimulate the patient's power of resistance.

Localized Muscular Atrophy in Diabetes.—Localized areas of muscle atrophy that suggested the presence of a specific process independent of insulin atrophy were observed in six women with diabetes who had received insulin for from 4 to 11 years. The characteristic induration usually found in insulin lesions was not present in these cases, and the circumscribed areas were found in parts of the body other than those into which the drug was usually injected. Other authors found no evidence of insulin atrophy remote from the site where insulin was injected. A diagnosis of panatrophy was not justified because the skin of the atrophied areas was always normal, and, although the three patients had some neurological abnormalities, the muscle lesions did not correspond to any nerve distribution. This condition probably represents a specific diabetic lesion that is independent of insulin lipodystrophy.

*Isoniazid in Treatment of Miliary Tuberculosis and Tuberculous Meningitis. E. Messmer.—p. 605.

Isoniazid in Miliary Tuberculosis and in Tuberculous Meningitis.—The ages of seven patients treated with isoniazid ranged from 15 to 70 years. In the first three patients who had tuberculous meningitis and miliary tuberculosis an attempt was made to use isoniazid exclusively. The total daily dose averaged 15 mg. per kilogram of body weight, and 50 mg. of this amount was given by the suboccipital route. No therapeutic effect was noted with this treatment, whereas as soon as streptomycin and *p*-aminosalicylic acid were given, considerable improvement became evident. Exclusive administration of isoniazid was continued as long as it seemed compatible with the condition of the patient. The inefficiency of isoniazid was demonstrated particularly by the fact that, despite intrathecal injections, tubercle bacilli remained demonstrable in the cerebrospinal fluid. The objection that these might have been avirulent tubercle bacilli is refuted by the fact that cultures and animal experiments were positive. The fourth case is noteworthy because a relapse during treatment with isoniazid was followed by death within a few days. The fifth patient, a 70-year-old woman, who had tuberculous meningitis and pulmonary miliary tuberculosis was treated successfully during the acute stage with streptomycin and *p*-aminosalicylic acid. Soon intolerance for the latter drug became evident, and so isoniazid was substituted for it. When the treatment was continued with streptomycin and isoniazid, the result was equally favorable. It is believed that in this case the addition of isoniazid contributed to the favorable effect. The sixth and seventh patients had miliary tuberculosis without involvement of the meninges; in one of these the results of exclusive administration of isoniazid were unsatisfactory, and not until streptomycin was given did improvement become evident. Under the influence of the combined treatment miliary dissemination regressed within three months. In the seventh case, although fever subsided during the combined administration of streptomycin and isoniazid, roentgenoscopy revealed no regression of the miliary dissemination. The exclusive use of isoniazid does not produce satisfactory results in the treatment of adults with tuberculous meningitis or miliary tuberculosis.

Recovery from Fulminant Meningococcus Infection with Purpura.—Fulminant meningococcus infection with purpura is usually an acute disease. With timely and intensive therapy and the usual antishock treatment, the prospect of saving these patients is good. Björklund believes his case in a 5-year-old girl is the only one reported where the excretion of 17-ketosteroids and 11-oxysteroids was examined and determination of the serum electrolytes done before the start of treatment and during the acute phase of the infection. The normal values testified against marked irreversible injury to the adrenal cortex. The patient was moribund for some hours after admission, with shock and postmortem-like lividity, but improvement soon began and recovery occurred after about a week. Large doses of penicillin, sulfonamide, an adrenal cortex extract (Eschatin), desoxycorticosterone acetate, and vitamins C and K were given. The administration of cortisone instead of adrenal cortex extract is suggested. There seems to be a sequence from fulminant meningococcus infection and purpura with recovery, where shock and infection are controlled and the adrenal cortex is protected, to the same disease with fatal outcome, where necropsy reveals degenerative changes, and to the Waterhouse-Friderichsen syndrome, where necropsy discloses hemorrhages in the adrenal cortex.

Hyaluronidase in Toxemia of Pregnancy.—Ten women with toxemia of pregnancy were given from 2,000 to 4,000 viscosity units of hyaluronidase. The arterial pressure dropped in all, albuminuria decreased, headache became milder or disappeared, edema was decreased, and a marked euphoria followed. Laboratory tests revealed that the ratio between albumin and globulin had increased, and there was an even greater increase in the ratio between the urine and blood chlorides. The prothrombin (Quick) time also increased in all the patients. In one woman with severe eclampsia who went into coma a few hours after the delivery, eclampsia subsided following intramuscular administration of 3,000 viscosity units of the enzyme, and she left the clinic a few days later. In women with full-term pregnancies labor begins a few hours after the administration of hyaluronidase; in those with puerperal eclampsia there is a greater loss of blood during the delivery. This is ascribed to the decreased blood coagulability, as was indicated by the prothrombin time or to a congestion of the genital organs that follows the administration of hyaluronidase.

Delivery Induced by Hyaluronidase.—Hyaluronidase was administered alone to 28 women with full-term pregnancies to induce delivery and combined with other drugs to 9 women to overcome inertia uteri. A dose of from 250 to 1,000 viscosity units of the enzyme was repeated one or more times after one or several hours. Only one patient was given 3,000 units in a single dose. The activity of the uterus was restored in patients in whom labor was suddenly arrested. The contractions reappeared and became increasingly forceful, while a progressive dilatation of the cervix followed. The effects were more pronounced and quicker to appear in patients in whom the membranes had ruptured prematurely. The motor stimulation of the uterus was achieved also in women who were in their fourth and seventh month of pregnancy and whose fetuses were dead. Hyaluronidase was combined with sparteine and thymophysin for some patients in whom additional stimulation was needed to accelerate the delivery and with lyspasmin for women in whom there was delayed dilatation associated with a tendency to spasm. The results obtained were better than when these drugs are given alone. The author made also some in vitro studies and concludes that the enzyme does not stimulate the uterus directly but exerts its influence on the factors, especially hormonal, that govern labor.

*Fatal Pulmonary Embolism in Course of Treatment with Anticoagulants. W. R. Merz.—p. 407.

Fatal Pulmonary Embolism and Anticoagulant Therapy.—The occurrence of fatal pulmonary embolism is reported in five men and five women treated with anticoagulants for thrombosis. The diagnosis was established by necropsy. Either because the dose of the anticoagulant used was too small or because the treatment was discontinued too early, the thrombus continued to grow without clinical manifestations. Anticoagulant treatment prevents the thrombus from becoming fixed to the wall of the vein, and as a result there were no changes in the pulse and temperature and in the subjective complaints. The thrombus may easily break loose, however, and cause sudden and fatal pulmonary embolism. In addition, unexpected pulmonary embolism or pulmonary infarction may occur when the dose is too small or when the effects of heparin and bishydroxycoumarin (Dicumarol) do not overlap while bishydroxycoumarin is being substituted for heparin, as well as with inadequate prophylactic doses of anticoagulants. *The thrombotic process can be arrested only* by the administration of heparin or substances with a similar effect. Protection against the risk of fatal pulmonary embolism may be provided by the empirically determined minimal dose of 40,000 I. U. of heparin given intravenously in divided doses over 24 hours. As a rule, smaller doses should never be used. For the first 24 hours, when the risk of pulmonary embolism is greatest, doses of 60,000 to 100,000 I. U. are recommended. The also empirically determined minimal duration of treatment with anticoagulants is three weeks, even in patients who apparently seem to respond well to the treatment.

Toxoplasmosis in Human Beings: First Case in Argentina. R. A. Borzone and P. Lapieza Cabral.—p. 489.
*Placental Grafts: 400 Cases. J. Uranga.—p. 490.

Placental Grafts in Painful Articular Diseases.—The group of 400 patients reported here had chronic rheumatoid arthritis, arthrosis, lumbosciatic syndromes, neuralgia of the brachial plexus, painful shoulder, periarthritis of the shoulder, and similar conditions. The treatment consisted of implantation of desiccated placental grafts and of daily intramuscular injections of a placental extract. The injections were given in a series of 20. Grafting was done between the fifth and seventh day after the injections were begun. Grafting was made under the skin of the abdominal region or near a joint, if only one joint was involved. The effect of placental grafts lasts for two or three months or longer, after which the treatment is repeated if painful symptoms reappear. The results were good in some cases and spectacular in others. The treatment controlled pain in all cases. Local suppuration or hematoma did not occur.

*Medicamental Treatment of Arterial Hypertension: Preliminary Report on Personal Experiences with Hexamethonium. V. Rønnov-Jessen and V. Bech.—p. 589.
Treatment of Essential Hypertension with Hydergin. P. Bechgaard and L. Paulsen.—p. 600.
After-Examination of Patients Operated on for Hemorrhoids. M. Felbo and O. Kofod.—p. 605.
Rupture of Tendon of Long Head of Biceps Muscle. A. Astrup.—p. 608.

Treatment of Arterial Hypertension with Hexamethonium.—Rønov-Jessen and Bech's routine treatment with hexamethonium now consists of combined oral and parenteral administration of the drug. They believe that hexamethonium should be used only in severe malignant hypertension. It should be used only with close supervision when there is severe impairment of renal function, and it must be used only in persons of normal intelligence because of the cooperation called for on their part. Treatment should probably always be started in a hospital, as it may at times be difficult to establish a suitable dosage. A rigid age limit is not set; the patient's physiological age must be considered primarily. Seventeen *patients were treated for from two to eight and a half months.* In all patients the blood pressure measured in the erect position was reduced during the day, the systolic pressure by an average of about 60 mm. and the diastolic by 30 mm. In 14 cases the subjective symptoms of hypertension abated during the treatment. In 10 patients under treatment for three months or longer there was improved capacity for work, and in some there was improvement in the objective symptoms. At the start of treatment undesired effects were usually seen, including constipation, vertigo, and impaired vision; *most of these* effects disappeared within a month or two. The authors say that, while hexamethonium has introduced a significant epoch in the treatment of hypertension, it is not an ideal hypotensive agent, as the treatment is too complicated.

Malignant Tumors of Sympathetic Nerve Cell Origin in Childhood. F. Ernst and E. Wiesner.—p. 336.
Electrical Stimulation of Gastrocnemius Muscle and Venous Circulation. F. Kaindl, F. Schuhfried and B. Thurnher.—p. 340.
*Antihemophilic Plasma Therapy for Severe Hemorrhage in Hemophiliacs. R. Jonas, H. Gross and H. Huber.—p. 341.

Antihemophilic Plasma Treatment of Hemophiliacs.—Irradiated human antihemophilic plasma produced in the United States was used in the treatment of severe hemorrhage in three hemophiliacs, aged 5, 15, and 20 years respectively. The 5-year-old boy bled after tonsillectomy; the child was given blood transfusions, vitamins K and C, and hemostatic agents for 15 days but oozing continued. On the 16th day the patient was given 50 cc. of irradiated antihemophilic plasma with 55 cc. of blood intravenously. An additional 250 cc. of the irradiated antihemophilic plasma was given in divided doses of 50 cc. at 12 and 24 hour intervals. Bleeding was definitely arrested, and the patient was discharged on the 28th postoperative day. The same amount of 300 cc. of the irradiated antihemophilic plasma was required for the arrest of the bleeding in the 15-year-old patient with massive and prolonged renal hemorrhage. Administration of 100 cc. of the antihemophilic plasma adequately controlled a moderately severe renal hemorrhage in the 20-year-old patient. The authors consider the irradiated human antihemophilic plasma the safest and most reliable agent for control of severe hemorrhages in hemophiliacs provided it is given in doses of 50 cc. at most 12 hours apart and whole blood transfusions are also given for the replacement of the blood loss. Except for the locally applied Topostasin, a proprietary thrombin preparation obtained from purified cattle plasma, the authors consider all other hemostatics ineffective, whether applied locally or parenterally, in small or large doses.

BOOK REVIEWS

Physiological Foundations of Neurology and Psychiatry. By Ernst Gellhorn, M.D., Ph.D., Professor of Neurophysiology, University of Minnesota, Minneapolis. Cloth. $8.50. Pp. 556, with 107 illustrations. University of Minnesota Press, Minneapolis 14, 1953.

The author, a leader in the field of neuropsychiatric research, is fully competent to collect, assess, and discuss critically the physiological foundation of research on the mechanisms underlying regulation of neuronal activity. His monograph covers the various factors of regulation, the physiology and pathology of movements, the basis of consciousness, autonomic physiology, and the applications of our knowledge to an understanding of schizophrenia and the basis for shock and carbon dioxide therapy, as well as a discussion of autonomic tests in mental disorders. Fully documented and illustrated, with an extensive bibliographic index, the text is fundamental for the specialist in laboratory investigation and clinical experimentation. Neurohumors and neuropharmacology, neuroendocrine action, homeostasis, and similar topics are discussed in an authoritative and comprehensive manner. Clinical and experimental literature is carefully integrated, presenting a clear picture of rapid advances in the last few years. The style of writing is clear, and the evaluations are distinctive. The book is highly recommended.

The Inside Story: Psychiatry and Everyday Life. Compiled under direction of Fritz Redlich, M.D., Chairman, Department of Psychiatry, Yale University School of Medicine, New Haven, Conn. Text written by June Bingham. With collaboration of Jacob Levine, Ph.D., Chief Clinical Psychologist, Veterans Administration Hospital, Newington, Conn. Cloth. $3.75. Pp. 280, with illustrations. Alfred A. Knopf, Inc., 501 Madison Ave., New York 22, 1953.

In psychiatry more than in any other field of medicine there has been an urge to advise the layman of the developments and problems of the field. This is unusual, because in all other disciplines the orientation is the opposite and is primarily directed toward making doctors more aware of patients and their problems. Many approaches have been employed by psychiatrists in this indoctrination process. There have been biographies, popular reprints of basic works, lectures, psychiatric novels, and even statistical studies of sexual behavior. It is strange that a cartoon analysis has not been used before this time. This is a unique approach and is especially valid, for the gifted and clever cartoonist presents a skilled layman's analysis.

The authors have chosen a series of cartoons and arranged them in an orderly pattern from the viewpoint of mental mechanisms and interpersonal relationships, with a correlated text. The connection between cartoon and text is left to the reader, but the relation is obvious. The cartoons are well chosen and cover many old favorites, including cartoons of psychoanalysis from *The New Yorker*. It is disappointing that the works of Steig and of Lichty, both of whom bring a rare penetration with cynical overtones to the psychological foibles and abnormalities of man, were omitted. The authors, however, were unable to include all the cartoonists, and it was impossible to obtain permission from some. It is likely that omission of some of the favorites was on this basis. With psychiatry developing more and more a holistic approach and tending to include international relationships, it is unfortunate that some political cartoons, such as those of Herblock, could not be included. Many of these classics, however, have uncovered or pointed out traits of prominent people, and the inference of mental mechanisms by inclusion in this book would be too obvious and perhaps repugnant. While it is considered proper for cartoonists to lampoon prominent citizens, it would not be proper to analyze these same lampoons from a psychiatric standpoint.

The text of the book is a sort of lexicon with a series of definitions and elaborations, often illustrated by informal case reports. There is a good over-all exposition of psychiatry that has a tendency to keep a balance among the many facets of psychiatric thinking. The text is enhanced by quotations from thinkers in many fields, including St. Augustine, Shakespeare, Freud, George Bernard Shaw, and Disraeli, as well as contemporary psychiatrists.

The content of the text follows the same pattern as the cartoons. The content cannot be, nor was it meant to be, a textbook of psychiatry. This book is primarily for the layman, and the physician needs to be familiar with it if he treats patients who have studied it. Careful reading of the text should lead to little misapprehension regarding mechanisms involved in normal and abnormal people. The occasional easy handling of moral matters in a book written primarily for laymen is a cause for some concern. This, of course, is not a special problem in this book, but rather in much psychiatric thinking. The book follows the concept that if most of the people do something, it is normal. There is no sharp distinction between average and normal. If this is so, head-hunting or cannibalism should be considered normal and acceptable in certain aborigines; therefore, was it not improper to discourage the cannibals and the head-hunters, since they were doing the "average" or "normal" act for their civilization?

There are a few ambiguities in the book; for example, in the last chapter the authors state that psychiatrists, through their treatment of patients and in their books for the general public, attempt to dethrone the old king (the unconscious conscience) and encourage the average person to govern himself consciously. The psychiatrists do not know what the result will be; they only have faith. In another paragraph, the authors point out that antisocial personalities and character neuroses are attributable to "atrophy of the conscious and unconscious conscience." Could "atrophy" not be induced?

This easily readable book, which touches only lightly on the whole field of psychiatry, is clearly and concisely presented for the layman. Most important, it employs a medium well known to all laymen, namely the cartoon, and from this medium develops an understanding of psychiatry; therefore, it serves a very useful purpose.

X-Ray Sieve Therapy in Cancer: A Connective Tissue Problem. By Benjamin Jolles, M.D., D.M.R., Consultant Radiotherapist, Physician i/c Radiotherapy Department, General Hospital, Northampton, England. With foreword by Sidney Russ, C.B.E., D.Sc., F.Inst.P. Cloth. $6. Pp. 192, with 51 illustrations. Little, Brown & Company, 34 Beacon St., Boston 6, 1053.

The author of this little volume has been interested in sieve therapy for over 10 years and is thoroughly qualified to write on the subject. The book is divided into three parts. The first concerns the importance of connective tissue in tumor genesis and in resistance to tumors and destruction and resolution of malignant growths treated by ionizing radiation. The second part discusses the importance of the treatment of a tumor, the phases of the human genesis, and the importance of producing structural changes that will lead not only to the resolution of a growth but also to alterations that affect the tissues in which the tumor arose. The third part concerns indirect radiation effects and principles and application of the sieve in radiotherapy.

There have been many comments on sieve therapy, some favorable, others not. The author has described in a meticulous manner the importance of accuracy in preparing a patient for treatment, daily observation of the patient, and other factors concerned with proper radiotherapy. Even if the sieve therapy was a failure, the methods used by the author and his careful attention to the patient are very important.

Every radiologist should read this volume even though he does not use the method. Unless special care is used with the method, it would seem unwise to employ it. The book reviews 54 patients who were treated by the author, and it is a guide for employing the sieve method. The work is published on

---

The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

fine paper, with good print and excellent illustrations, and it can be recommended for every radiologist interested in therapy.

Anatomy of the Autonomic Nervous System. By G. A. G. Mitchell, O.B.E., T.D., M.B., Professor of Anatomy and Director of Anatomical Laboratories in University of Manchester, Manchester, England. Foreword by Sir James Learmonth, K.C.V.O., C.B.E., Ch.M., Regius Professor of Clinical Surgery and Professor of Surgery in University of Edinburgh, Edinburgh. Cloth. $10. Pp. 356, with 131 illustrations. [Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2]; E. & S. Livingstone, 16 and 17 Telviot Pl., Edinburgh 1, 1953.

This new treatise on the sympathetic nervous system is a pleasure to read; it is well and clearly written, the illustrations are good, and a thorough bibliography and a complete index are included. A brief historical survey introduces the subject and sets the style of the book. The reader will be particularly impressed by the refreshing treatment of the autonomic system as part of the entire nervous system and not as a separate system. The author shows in a clear, detailed manner how the sympathetic and parasympathetic nervous systems are integrated with the central nervous system and the peripheral somatic nerves. He is thoroughly conversant with the literature and has documented each point carefully. This book can be recommended to specialist and beginner alike; both will find it informative, accurate, and interesting.

A Policy for Scientific and Professional Manpower: A Statement by the Council with Facts and Issues Prepared by the Research Staff. By National Manpower Council. Cloth. $4.50. Pp. 263, with 4 illustrations. Columbia University Press, 2960 Broadway, New York 27; Oxford University Press, Amen House, Warwick Sq., London, E.C.4, 1953.

This volume is a publication of the National Manpower Council, which was established at Columbia University in 1951 under a grant from the Ford Foundation. The Council was founded to study manpower problems, particularly those concerned with the quality of personnel. This is its second report; the first, "Student Deferment and National Manpower Policy," was published in April, 1952.

This study contains policy recommendations in part 1. The discussion "Facts and Issues About Scientific and Professional Manpower" comprises part 2. While general statements about higher education receive some attention, emphasis is focused on physicians, engineers, physicists, and teachers, as representative of the broad group included in professional and scientific manpower. The increase in the number of occupations classified as professional or scientific is discussed, and changes that have occurred in professional educational requirements are reviewed. The volume covers such varied topics as the economic factors affecting education, employment markets, and the potential of higher education as compared to actual achievement. The study is, of course, particularly concerned with the role of these persons in the emergency situation.

The four professional groups are considered in the light of supply and demand, characteristics of each profession, and patterns of employment. A chapter devoted to the role of physicians includes a survey of the data used in estimating shortages by 1960 and an excellent discussion of the shortcomings of the statistical procedures. Herbert Klarman, Ph.D., who prepared the original draft of this chapter, did not note that the total number of physicians in 1960 is likely to be 245,000 instead of 233,000. The difficulties inherent in attempting to make any real estimate of the number of physicians needed in our economy are recognized, and the importance of quality rather than quantity is emphasized: "To increase the number of doctors trained at the expense of the quality of the training would be worse than useless." The underlying thesis of the chapter seems to be that there must be a doctor shortage, although there is no way of proving or measuring it. This chapter is, therefore, a strange combination of logic and whimsy.

The report makes some specific suggestions for the future of the medical profession, including more and larger medical schools, more efficient use of physicians by the armed forces, and increased cooperation in hospitals, health centers, and clinics among members of the profession (a suggestion taken from the report of President Truman's Commission on the Health Needs of the Nation). Some of the difficulties in implementing the suggestion for more medical schools and an increase in the number of medical students at established schools are recognized. Among those noted are the problem of cost and the hindrances to the expansion of facilities if quality of education is to be maintained. The "shortages" in state hospitals and public health departments are "largely, though by no means entirely, an economic problem. Low salaries . . . lack of professional prestige . . . unfavorable working conditions. . . ." The "obvious" conclusions reached do not follow from the information presented.

Aside from the inclination, throughout the book, to insist that shortages exist, whether proved or not, the Council has made a valuable contribution to study of the professions and American education. It has corrected one of the most glaring omissions of previous studies: the medical profession is studied in the context of the requirements of our society for other professional and scientific personnel, and not in the vacuum of medicine alone. Apparently the "shortage" of physicians is not the most serious problem.

The final chapter, "Manpower Policies in a Democratic Society," is a particularly penetrating discussion of the formation of such policy in a society that gives the individual freedom of choice of occupation. There are strong limitations on direct action: "The major governmental influence upon the supply of scientific and professional manpower is a result of educational measures of various kinds."

The shortcomings of any forecasts of future demand in relation to progress in technology and science, future changes in the roles and responsibilities of auxiliary personnel in any of these fields, problems raised by the emergency sacrifice of long-term goals, and the need for the best use of highly trained manpower in a wartime society are reviewed. The conclusions emphasize the importance of more basic information on scientific and professional manpower and the need for better methods of predicting short and long-term requirements. This study is particularly useful in combining all the information available; for example, table 1 (page 44), "Professional, Technical and Kindred Workers in the United States, by Major Fields, 1870-1950," and the accompanying graph showing the percentage relationship. Beyond this useful summary of data the study does little more than point up the necessity for more study.

Differentialdiagnose innerer Krankheiten: Eine kurzgefasste Darstellung für Ärzte und Studierende. Von Dr. Robert Hegglin. Second edition. Cloth. 55 marks. Pp. 556, with 250 illustrations. Georg Thieme, Diemershaldenstrasse 47, (14a) Stuttgart-O; agents for U. S. A., Grune & Stratton, Inc., 381 Fourth Avenue, New York 16, 1953.

The second edition of this brief text on differential diagnosis appears just a year after the first edition. New sections on headache and pain in the extremities have been added. There is no change in the general principle of discussing differential diagnosis from the viewpoint of the general practitioner and on the basis of "presenting" symptoms and signs rather than diseases. A preliminary chapter discusses this viewpoint in detail and is followed by sections on anemia, hemoglobinuria, the hemorrhagic diathesis, simple fever, febrile diseases with meningeal symptoms, febrile diseases with joint pains, and the significance of single symptoms in diagnosis of febrile diseases. There are also sections on headache, dyspnea, cardiac arrythmias, electrocardiographic changes in myocardial damage, cyanosis, thoracic pain, hypertension, and renal hypertension. Pulmonary diseases are discussed, including tuberculous infiltration, primary pneumonia, secondary pneumonia, and nontuberculous and nonpneumonic diseases such as atelectasis, echinococcosis, tumors, pneumonoconiosis, and silicosis. The next chapters cover bilateral, infectious, and neoplastic enlargements at the hilus of the lung; predominantly one-sided hilus enlargements; and lesions causing mediastinal enlargement. Other subjects include causes of pain in the abdomen, diarrhea, jaundice, splenomegaly, urinary conditions (hematuria, albuminuria, pyuria, and cylindruria), causes of edema, pain in the extremities and that originating in the spinal column, and causes of loss of consciousness.

Every main section is followed by a bibliography, mostly German, but also containing references to English, French, Scandinavian, and American literature. There are numerous excellent graphs and black and white illustrations, many of which are reproductions of roentgenograms, with occasional pictures of patients showing attitudes characteristic of ailments producing postural changes. The color illustrations are excellent. The text is followed by a good subject index. The book is attractively bound in blue cloth and is smaller and considerably thinner than the standard American textbook. The paper is of excellent quality, and the typography is clear cut. The author, in general, has succeeded in his aim of producing a brief work on a broad subject. In some sections the descriptions of disease are too brief. In the discussion of coccidioidomycosis, for example, it is not made entirely clear that valley fever is the preliminary stage and that some patients later have skin lesions simulating blastomycosis; that in diverticulosis some patients may have severe hemorrhages; that in trichinosis the larvae may be recovered from the blood and spinal fluid; that pericarditis is often painless; and that cervical ribs may produce intermittent claudication on use of the arms or sensory changes in the hands. These, however, are minor faults, and the book should be helpful to the general practitioner as a reference in doubtful diagnoses.

Clinical Endocrinology. Volumes I and II. By Lewis M. Hurxthal, M.D., F.A.C.P., Head of Department of Internal Medicine, Lahey Clinic, Boston, and Natalija Musulin, B.S., M.D. Cloth. $24 per set. Pp. 749; 751-1599, with 629 illustrations. J. B. Lippincott Company, 227-231 S. Sixth St., Philadelphia 5; Aldine House, 10-13 Bedford St., London, W.C.2; 2083 Guy St., Montreal, 1953.

These impressive volumes are not the expected cyclopedic textbook but are an outline of endocrinology. An outline may well serve its purpose as an introduction or recapitulation of details elaborated in conventional language. Material presented in outline must of necessity appear dogmatic (which is undesirable in so labile a field as endocrinology); therefore, controversial topics cannot be presented in an intelligible manner. Owing, however, to the wide clinical experience of the authors and their thorough coverage of the vast literature, the disadvantages intrinsic in an outline presentation have been reduced to a minimum.

The subject of endocrinology has been covered adequately and is organized in a masterly manner. The material is sound and up-to-date, although the literature and text of the preclinical sections lack the quality of the clinical sections. The book is presented in a well-printed, easily read format. Illustrations and case reports that are appended to the chapters are, for the most part, well chosen and original and constitute one of the most valuable features of the book. Many references are also included, but there is an apparent bias toward the older literature, with few references to that of the last decade.

The material included in these volumes would have been easier to comprehend in the conventional text form, with perhaps certain portions retained in outline form. In their present arrangement the volumes will be of greatest value to the endocrinologist who desires to refresh his memory on a certain subject. The general reader, however, will probably find the outline presentation less satisfying than a conventional text.

Biochemistry of Disease. By M. Bodansky and O. Bodansky. Second edition revised by Oscar Bodansky, M.D., Ph.D., Professor of Biochemistry, Sloan-Kettering Division, Cornell University Medical College, New York. Cloth. $12. Pp. 1208, with illustrations. The Macmillan Company, 60 Fifth Ave., New York 11, 1952.

The first edition of this book appeared in 1939. It was designed neither as a textbook of biochemistry nor as a manual of laboratory procedures but, rather, as a compendium of the biochemical aspects of various diseases. The second edition follows the general pattern of the first, but the text has been expanded and revised in the light of recent advances in clinical biochemistry. A useful addition is an appendix of mean normal biochemical values together with a discussion of statistical evaluation of the normal range. The book is recommended to physicians and laboratory workers desiring an understanding of the biochemical processes in various pathological states in order to apply intelligently the many diagnostic and prognostic laboratory procedures currently available.

Chemical Physiology of Contraction in Body and Heart Muscle. By A. Szent-Györgyi. Cloth. $4.80. Pp. 135, with 29 illustrations. Academic Press, Inc., 125 E. 23rd St., New York 10, 1953.

In a work intended for the biologist, Szent-Györgyi outlines his present theories on muscle with regard to composition and structure, chemical and physical mechanisms of contraction and relaxation, and effects of such factors as temperature, ions, drugs, and regulators. Cross striated body muscle, heart muscle, and uterine muscle are considered. According to the author, the book "is not offered as a comprehensive and objective review; it is the presentation of the problem, as I see it, after fourteen years' acquaintance with muscle." The material is well organized and presented, and the printing is excellent. There is no index, probably because of the ephemeral nature of such a theoretical work.

Heart and Circulation: Diagnosis and Treatment. By Meyer Sclar, M.D., F.A.C.C., Chief in Cardiology and Senior Attending Physician, Unity Hospital, Brooklyn, New York. Assisted by Jacob Melnick, M.D. Cloth. $7.50. Pp. 357, with illustrations. Froben Press, Inc., 1776 Broadway, New York 19, 1953.

This manual on diagnosis and treatment of cardiovascular disease is original in its approach to the subject. The basic concepts of cardiac physiology and pathology and the clinical course and therapy of various syndromes are presented from the author's experience in practical cardiology. This personal experience is also reflected in the subjective tone of the book, which overstresses the value of certain aspects, such as that of the trigger mechanism of cardiac pain, while other important practical problems, like the Adams-Stokes syndrome, are dealt with completely inadequately with regard to mechanism and treatment. Little space is devoted to chronic cor pulmonale, and the author fails to mention the entity of acute nonspecific pericarditis, while, on the other hand, mitral surgery is described in minute technical detail. Some of his statements will hardly be approved by experienced cardiologists, e. g., the application of the term myocardosis, the statements about the relative incidence of right and left bundle branch block, and the views concerning the use of hypertonic solution of glucose for severe dyspnea.

The typography of the book is good, the language is clear, and the illustrations are well selected, except for most of the electrocardiograms, which are poor technically and with regard to modern standards. This manual is recommended to the practitioner for orientation in the rapidly expanding field of cardiology and as a guide to cardiovascular diagnosis.

Die neuzeitlichen Brustwand- und Extremitäten- Ableitungen in der Praxis. Von Prof. Dr. Herbert Reindell, Oberarzt der medizinischen Universitätsklinik Freiburg i. Br., und Dr. Helmuth Klepzig, Assistent der medizinischen Universitätsklinik Freiburg i. Br. Mit einem Geleitwort von Prof. Dr. Ludwig Heilmeyer, Direktor der medizinischen Universitätsklinik Freiburg i. Br. Second edition. Cloth. 24.60 marks. Pp. 188, with 70 illustrations. Georg Theime, Verlag, Diemershaldenstrasse 47, (14a) Stuttgart-O; agents for U. S. A., Grune & Stratton, Inc., 381 Fourth Ave., N. Y. 16, 1953.

This German monograph on multiple chest leads and aV limb leads has been thoroughly revised and expanded. The text includes a discussion of the normal precordial electrocardiogram, its normal variations, and all important abnormalities, and has been rearranged and enlarged with a number of new and instructive illustrations. Although only a few actual vectorcardiograms and schematic drawings of abnormal vector loops have been added, the interpretation of the electrocardiogram is now largely based on vectorial concepts, in conformity with recent trends in clinical electrocardiography. Influenced by newer German work, the terminology has been partly changed or adapted. The authors maintain their concept of two types of ventricular strain, one causing simple delay of ventricular depolarization ("Verspaetungskurve") and the other causing, in addition, alterations of repolarization ("mit Funktionsstoerung"). The necessary amplification of illustrations has been made in this chapter but unfortunately has been omitted in the section on bundle branch system block. The printing and the quality and reproduction of illustrations are excellent. More than 100 recent references have been added. This monograph can be recommended as an up-to-date survey of clinical electrocardiography.

QUERIES AND MINOR NOTES

THE INTESTINAL FLORA

To the Editor:—*How can the bacterial flora of the intestinal tract be changed? Please outline a procedure for accomplishing this. I know aureomycin may suppress or inhibit the bacterial flora and thus allow Monilia (Candida) infection to flourish. Is the intestinal bacterial flora constant?*

R. J. Martoccio, M.D., Utica, N. Y.

Answer.—The intestinal flora can be changed either by administration of drugs or by modification of the diet. The former includes administration of the locally acting sulfonamides, such as phthalylsulfathiazole (Sulfathalidine) or succinylsulfathiazole (Sulfasuxidine), and antibiotics, such as oxytetracycline (Terramycin), chloramphenicol (Chloromycetin), and aureomycin. The latter includes the use of a lactovegetarian diet supplemented by lactose. Except for specific purposes, such as the elimination of Eberthella (Salmonella) typhosa and Shigella dysenteriae from the intestinal tract or preoperative preparation for intestinal resection, qualitative or quantitative changes in the intestinal flora by the use of drugs are of dubious value. In fact, they may be distinctly harmful, as is the case with the prolonged use of antibiotics that interfere with the bacterial synthesis of B complex vitamins or that favor the development of moniliasis. The intestinal flora is inconstant, and its composition depends on a number of factors, such as the degree of gastric acidity and whether the diet is vegetarian or includes meat. The intestinal flora of a breast-fed infant consists largely of Lactobacillus bifidus. With a mixed diet, the upper small intestinal flora of a normal adult consists chiefly of enterococci. Farther on toward the large intestine, the flora becomes more complex and includes coliform organisms, staphylococci, and various gelatin-liquefiers. In the colon, in addition to these organisms, enterococci and anerobic spore bearers are found. These are fairly constant in man, but many other types, too numerous to mention, are encountered in smaller proportions. The diet and the number of organisms ingested largely determine the type of intestinal flora in the healthy human.

EXPIRATION DATES ON BIOLOGICAL PRODUCTS

To the Editor:—*Biological products, such as vaccines, antibodies, and the antibiotics, are labeled with expiration dates. What precisely do these expiration dates mean, and how are they determined? Can the products be used after the expiration date, if kept at optimum storage temperature? If there is a loss of potency, can the dosage be increased proportionately, and, if so, what method would be used to determine the increase?*

M.D., Kentucky.

Answer.—Manufacturers of biological products sold in the United States are obliged to comply with the requirements of the National Institutes of Health of the United States Public Health Service. The expiration dates on biological preparations vary with the different biologicals, and their purpose is to indicate the date beyond which the contents cannot be expected beyond reasonable doubt to yield their specific results. The expiration dates are established by the National Institutes of Health on the basis of experimental investigations and practical experience. More detailed information may be found in "Dating Decision Number 10," issued May 15, 1947, by the United States Public Health Service, which contains "The Dating Periods Recommended for Those Biological Products Specified in the Biologics Section of the Public Health Service Act of July 1, 1944." This pamphlet, known as Miscellaneous Publication No. 38, is obtainable from the Superintendent of Documents, United States Government Printing Office, Washington 25, D. C., for 5 cents. The expiration dates of antibiotics are determined in compliance with the regulations of the United States Food and Drug Administration. They vary with the different antibiotics and with different dosage forms of the same antibiotic and are intended to signify the date beyond which the product should not be used. With antibiotics, as with biological preparations, it is important that the recommended storage conditions be observed. Some degree of potency is probably retained in all such products even after the expiration date, provided they have been stored in accordance with recommended requirements, and although the use of such out-dated products may be necessary in emergencies, it is advisable wherever possible to employ preparations bearing expiration dates that have not been passed.

ALLERGY AND SINUSITIS

To the Editor:—*During the winter acute sinusitis develops in a patient, which at times is followed by formation of nasal polyps, which subside after several weeks of symptomatic treatment. Intradermal tests for allergy to dust, feathers, and a variety of foods gave positive results. Results of tests for allergy to pollens and other inhalants were negative. 1. Is it necessary to eliminate these allergens if, on exposure to them, no clinical symptoms are produced? 2. Is desensitization with dust and feather extracts of value in preventing the nasal symptoms? 3. For how long should such injections be given? 4. What relation have foods causing positive reactions in intradermal tests to clinical sensitivity? 5. Are antihistamines of value in treatment of allergic sinusitis? Which one is recommended for use by ambulatory patients?*

M.D., New York.

Answer.—1. Since the patient had positive intradermal test reactions to house dust and feathers, exposure to these should be prevented as much as possible. The use of rubber pillows and rubber mattresses or dust-proof mattress covers should be urged. The bedroom should be as dust-free as possible, and no rugs or draperies should be permitted in the room. Household pets should be removed. The living room should be kept "spic and span," and any loose pillows that may contain feathers or kapok should be removed. Use of a good vacuum cleaner is essential. 2. Hyposensitization to feathers and dust extracts is of value in preventing or lessening nasal symptoms. 3. The injections should be given as long as the patient has symptoms. At the start, it is customary to give the injections twice a week, later once a week, and then once every two weeks. If the symptoms disappear for at least a month, the injection therapy should be discontinued, but it should be resumed if symptoms return. 4. In recent years, it has become evident that intradermal tests with food extracts are not nearly so reliable as similar tests with inhalant materials, e. g., dog hair or house dust. Some allergists have gone as far as to stop performing food intradermal tests, but it is probably better to continue carrying out these tests with important foods. Certain food extracts, such as those made from spices, cause many positive reactions; these tests should be avoided. Positive results in tests for the important foods should be followed up clinically, i. e., every food that produces a reasonably strong reaction should be removed from the diet for a week or two. These foods should then be given separately in large quantities at weekly intervals, when the patient is feeling good, to determine whether symptoms will result. If the result of such a clinical test is negative, the food can be eaten; if positive, its use should be avoided. 5. Antihistaminics are probably as valuable in allergic sinusitis as they are in allergic rhinitis, since the lining of the nasal membrane is continuous with that in the nasal sinuses. There are many available antihistaminics on the market. Those that have a strong sedative action should not be used during the day, but they are useful at night, be-

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

cause they help the patient obtain a good sleep. Those that have milder sedative action, e. g., thonzylamine (Neohetramine), are recommended for daytime use; their use is especially important in patients who drive cars or who work in dangerous occupations in which drowsiness might be a factor in causing an accident.

SUDDEN DEATH

To the Editor:—*During the past six months I have had three elderly patients who died suddenly in the hospital. Two were recuperating from influenzal pneumonia, and the other had had episodes of bronchial asthma for years. The two with influenza had irregular heart beats when they were admitted, and their families were cautioned about the possibility of sudden death. The asthmatic patient had ectopic beats and had been treated for "heart trouble" for years. To my knowledge, none of these patients had ever had angina pectoris or a coronary occlusion. All three died in less than a minute. One did not even move, and his neighbor in the next bed did not know that he had died. What should be reported as the cause of death in these three patients?*

M.D., North Carolina.

Answer.—Whenever a patient dies suddenly and unexpectedly, the cause of death is a matter of speculation if no autopsy is done. All of these patients had circulatory disease, so it may be assumed that death was produced by some circulatory accident. The commonest type in the older age group is coronary occlusion with myocardial infarction. If the onset of ventricular fibrillation is immediate, death occurs almost instantaneously. This has been found to be the cause of death in many instances in which persons have died while asleep. In addition to this, it may be assumed that the patients with irregular rhythm had auricular fibrillation. The discharge of a thrombus from the fibrillating auricle could produce a coronary embolism or a pulmonary embolism, with immediately fatal outcome. In this age group, the occurrence of massive cerebral hemorrhage is a possibility. Rupture of an aortic aneurysm, either thoracic or abdominal, should be considered. A dissecting aneurysm that perforates into the pericardial sac and produces cardiac tamponade may cause sudden death. The lack of a history of these conditions does not preclude any of them as possible causes. Indeed, thrombi are known to form more readily during episodes of acute infection and periods of rest in bed.

NASAL IRRITATION IN A BAKER

To the Editor:—*A 28-year-old man, a baker, has for two years noticed almost constant burning and irritation of the nasal mucous membranes, with occasional bleeding. It is his opinion and mine that the flour is an irritant to these membranes. When he is away from work, the nasal symptoms improve. He has had no previous allergies, and skin tests for wheat give negative results. There is no itching, coryza, or sneezing. The patient has been advised to use a respirator. I have considered use of a silicone spray but do not know if such a preparation exists. Please advise proper treatment.* *M.D., Wisconsin.*

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—If the flour is a direct irritant and the patient's nose is normal, it would be expected that his fellow workers would also be affected. If this is not the case, some local "weakness" or susceptibility of his nasal mucosa, such as may depend on a chronic infection or a deformity from a deviated septum, should be considered. Allergy dependent on antibodies to wheat localized in the nasal mucosa is possible, even though skin tests continue to give negative results. Application of a drop of extract of whole wheat in a strength of about 0.01 mg. of nitrogen per milliliter to the lower turbinate on one side, with application of another drop in a strength of 0.1 mg. of nitrogen per milliliter if no reaction is observed within 20 minutes, may give useful information. If the extract is potent and produces positive skin reactions in known wheat-sensitive persons and if it fails to cause a reaction in this patient, allergy could be ruled out. The absence of sneezing, a discharge, and itching argues against allergy. Local treatments are not advisable for, although they may help at first, they may act as irritants later and cause additional harm. To prevent contact by use of a mask is the safest and best procedure. If allergy can be proved, specific desensitization by injections of wheat extract may be worth trying, but the results cannot be guaranteed. The man may have to change his job.

Answer.—Mechanical irritation from flour incrustation on nasal mucous membrane is a recognized disorder. Some flours contain bleaches or trace additives as improvers, calcium acid phosphate being an example of the latter. Some of these ancillary agents are irritants. At this time, silicone sprays for the nasal passages cannot be recommended, although silicone protective creams applied to the skin may possess some virtues. These silicones are only slightly soluble, so that any spray may contain solvents that would be distinctly irritating to mucous membranes; the possible solvents include benzene, carbon tetrachloride, acetone, and ethyl ether. Coatings of silicone on tissues are persistent, although chemical solvents make removal easy. While no respirator will fully protect a worker sensitized to flour, exposure will be distinctly lessened. The wearing of respirators that protect against toxic dust may be onerous, but in this instance the use of any respirator approved by the United States Bureau of Mines for protection against nuisance dust will aid greatly in diminishing exposure. Allergy to flour among bakers, while known, is a rarity. Due consideration should be given to the possibility of other causes.

TETANUS

To the Editor:—*How effective is tetanus toxoid in preventing tetanus when administered soon after injury? I have heard that active immunization proceeds rapidly enough to obviate the need for passive immunization with tetanus antitoxin. If so, how early should tetanus toxoid be given?*

W. D. Chipman, M.D., Los Angeles.

Answer.—If the possibility of tetanus infection is present after an injury, the administration of tetanus antitoxin is always indicated for a person who is not immune. Under such circumstances, tetanus toxoid should never be considered a substitute for tetanus antitoxin. Even in the case of a person who is known to have been actively immunized and for whom a "booster" dose of tetanus toxoid would seem to be the only requirement for protection, tetanus antitoxin is sometimes administered also, if the wound is of a serious nature or if there has been delay in prophylactic treatment.

VARIED HYPERTENSION WITH ARTERIOSCLEROSIS

To the Editor:—*A 63-year-old white man was examined routinely for pensioning purposes. His only complaint was a chronic cough. Examination revealed grade 2 retinopathy, some crackling rales at the lung apex posteriorly and anteriorly, a vital capacity of 73%, and a grade 2 systolic murmur in the aortic area. The blood pressure was 160/70 mm. Hg in the right arm, 90/70 mm. Hg in the left arm, 234/90 mm. Hg in the right leg, and 155/90 mm. Hg in the left leg. The oscillometric index was 8 in the right arm, 2 in the left arm, 8 in the right leg, and 3½ in the left leg. The spleen was questionably palpable. A grade 3 bruit and thrill in the left groin overlying the femoral artery were noted, and a Babinski sign was elicited in the left foot. Roentgenograms of the skull showed no abnormalities, and chest roentgenograms showed minimal tuberculosis and a heart normal in shape, size, and position. Results of all laboratory studies were within normal limits. The sputum was negative for acid-fast organisms. I would appreciate an explanation of this patient's bizarre hypertension.*

Louis Cohen, M.D., Topeka, Kan.

Answer.—While it is not probable that an exact diagnosis will be made, it seems possible that the problem is basically one of generalized arteriosclerosis. This is suggested by the presence of grade 2 retinopathy, a systolic murmur, a positive

Babinski sign, and a wide pulse pressure. The presence of arteriosclerotic obstruction on the left side is possible though it would be unusual. The bruit and thrill in the left groin suggest the presence of a dissecting aneurysm.

DESENSITIZING INJECTIONS

To the Editor:—*Is it safe to permit desensitization injections, for ragweed, dust, and bacteria, for example, to be given by a nurse or technician in the absence of a physician? I refer to the practice of giving the patient a vial of antigen and a schedule of doses so that he can receive the injections in the first aid or medical department of his place of work. If permissible, what precautions should be taken to minimize the possibility of reactions? To what extent is the company maintaining the first aid facilities liable in the event of a serious reaction?* *M.D., New York.*

Answer.—The question of safety in administration of desensitizing injections is a relative one. Serious reactions are at a minimum when the injections are given by competent allergists, but still they may occur in the hands of the most experienced. Desensitization procedures in the hands of nonspecialists are bound to yield a greater incidence of reactions. When given by a nurse who has no supervision, the possibility of the occurrence of reactions is even greater, although if the nurse is intelligent and experienced the danger may not be great. The major problem in allowing a nurse to give injections in the absence of a physician concerns the treatment of reactions, should they occur. Written instructions for the prevention and treatment of reactions should be furnished with the antigen and should include warning about the interpretation of the results of the preceding treatment, the gaging of the dose, and the avoidance of intravascular injections. Antihistamines or ephedrine may be used for mild symptoms and epinephrine for severer symptoms. Aminophylline may be needed. In instances of very severe reactions oxygen administration may be desirable. Obviously, it is in the treatment of serious reactions that the nurse alone may not be adequate. The question of liability undoubtedly is different in each state. It is suggested that the inquirer seek information on this point from medical insurance companies or from legal sources.

DIATHERMY CONTRAINDICATED OVER OR NEAR BONE PLATES

To the Editor:—*I often see patients who previously have had a fracture in which a bone plate and screws of stainless steel or Vitallium (a cobalt, chromium, and molybdenum alloy) were used for fixation of bone and had been left behind. Is it safe to give diathermy treatments to a knee, for example, if a stainless steel plate and screws are present in the femur 2 or 3 in. above the knee joint? Does a focus of increased heat develop at the site of the bone plate when heat is applied by diathermy to the surface of the skin directly over or near the bone plate?* *M.D., Connecticut.*

Answer.—There is a potential danger, both actually and theoretically, that makes it inadvisable to use diathermy to heat areas of the human body that contain metallic implants. In many instances no damage has occurred; however, it is generally felt that, in any condition in which metallic implants are present in or near the area to be treated, use of medical diathermy of any type is contraindicated. This is true also in instances in which metallic sutures or foreign bodies, such as bullets or shrapnel, are present.

SPEECH DISTURBANCE

To the Editor:—*Does inhibition of normal speech expression ever have an allergic basis?*

Walter A. Landry, M.D., Chester, Pa.

Answer.—Except for the temporary aphonia that may result from involvement of the vocal cords in allergy of the larynx, disturbance of speech is not one of the manifestations of allergy

CANCER AND INTESTINAL PARASITES

To the Editor:—*Is cancer of the bowel often or ever complicated by parasitic infections of the intestines?*

Henry Folb, M.D., Trenton, Texas.

Answer.—Any association of parasitic infection of the intestines and cancer of the bowel is more than likely coincidental. Some parasites, such as Endamoeba histolytica, may produce an inflammatory lesion of the colon associated with the development of polyps, which may eventually become malignant. In general, however, intestinal parasites are unimportant as a causative factor in colonic cancer. Some reports in the literature have titles that would suggest a causative relationship, i. e., "Malignant Potentialities in the Chronic Intestinal Lesion Produced by Amoeba Histolytica" (*Gac. méd., Guayaquil* **7**:33, 1952). There is, however, no suggestion of proof that the two are related, and no supporting data is given. A pathologist who had experience in the Philippines with the Philippine scouts reports that he did not see a single case of colonic cancer, although intestinal parasitic infection was common. A Greek pathologist stated that in Greece autopsy was done on many persons who had had intestinal parasitic diseases, but no increase in the incidence of bowel cancer was noted. There is a possible relation between schistosomiasis and cancer; there seems reason to believe that the mechanical and toxic irritations of the ova predispose to cancer of the urinary bladder.

ANESTHESIA FOR CIRCUMCISION

To the Editor:—*In Queries and Minor Notes in* The Journal *May 16, 1953, page 294, in answer to a question about anesthesia for circumcision, it is stated that it is necessary to avoid injection into the corpus cavernosum. This is a quotation from Lundy's "Clinical Anesthesia" (Philadelphia, W. B. Saunders Company, 1942, p. 121), and it is not correct. The best type of anesthesia for circumcision is produced by the injection of 10 cc. of 2% procaine into each corpus cavernosum laterally just below the symphysis pubis. I have used this method for 10 years and have never observed any ill effects. I refer you to an article by Magid and Culp entitled "Ideal Penile Anesthesia Obtained by Injection of Corpora Cavernosa"* (J. Urol. **50**:*508 [Oct.] 1943).*

Berwyn, Ill.

NO TESTES IN SCROTUM

To the Editor:—*Regarding the query "No Testes in Scrotum" in* The Journal *May 23, 1953, page 375, I wish to direct attention to an article by Dr. E. T. Engle* (Endocrinology **16**:*506, 1932), in which he states, "In the prepubertal intact monkey chorionic gonadotrophin induces tubular growth, descent of testes and an increase in the number of interstitial cells." Cramer* (Endocrinology **21**:*230, 1937) and Dorff* (J. Pediat. **8**:*704, 1936;* J. A. M. A. **110**:*1799 [May 28] 1938) pointed out that chorionic gonadotropin has been shown to be of definite value in the treatment of cryptorchidism when descent of the testes is not impeded by an anatomic obstruction. Dorff notes also in the same article in the* Journal of Pediatrics *that chorionic gonadotropin will produce in some patients not only descent of the testes but also enlargement of the penis. In a survey of the literature, Thompson and Heckel* (J. A. M. A. **112**:*397 [Feb. 4] 1939) estimated that the rate of successful response to chorionic gonadotropin therapy was 61%. In the limited number of patients that I have treated with this drug the results have been good. Exceptionally good results were obtained in a 32-year-old man who was refused admission to the military service because of small, undescended testes and a minute penis. With chorionic gonadotropin treatment, his sexual characteristics became normal to the extent that he was accepted by one of the services.*

DIAGNOSIS AND MANAGEMENT OF ABNORMAL UTERINE BLEEDING

Walter J. Reich, M.D., M. William Rubenstein, M.D., Mitchell J. Nechtow, M.D.
and
Jerome B. Reich, M.D., Chicago

Abnormal uterine bleeding is difficult to define. It might be stated that any bleeding that deviates from the usual established physiological cyclic menstrual pattern in an individual person must be considered abnormal; these deviations are mainly those of character, time, frequency, and amount of bleeding. One must remember that spotting is just as important a symptom as frank hemorrhage. It is lamentable to note the number of patients who are slow to seek medical attention when atypical bleeding does occur. In many cases undue waiting has prevented adequate relief and salvage. Advice should be sought at the first sign of abnormal bleeding, and the physician must be on the alert to consider the numerous potential etiological sources, making sure, above all, to rule out causes due to malignancy.

Each patient must be individualized and her history carefully evaluated. A thorough general physical and gynecologic examination, including a speculum, vaginal, rectal, and rectovaginal examination, must be done. One must first consider those sources that arise from an abnormality in the uterus per se. By far, the majority of clinical bleedings arise here, and a pathological diagnosis, as a rule, can be found. In those few patients who do not yield to a "source" diagnosis, constitutional and chronic diseases and functional factors must be looked for. Malnutrition, vitamin deficiencies, metabolic derangements, and intoxications must be considered. Hypertension and cardiovascular disease may give rise to local changes in the endometrial arterioles or produce marked passive congestion with manifest excessive bleeding.

Regardless of the presence of obvious disease in the generative tract, or of other constitutional factors, blood dyscrasias must be ruled out as a cause for bleeding. The leukemias and lymphomas must be considered. At times leukemic infiltration takes place in the uterus. Usually the cause of bleeding in dyscrasias is a dysfunction and/or decrease or complete absence in the number of blood platelets. Thrombocytopenic purpura must be differentiated. Here splenectomy may be the treatment, and, indeed, it may be life saving. Blood cell counts and blood smears, including a platelet determination, must be done in all cases of uterine bleeding.

Perhaps the commoner and more important pathological conditions giving rise to abnormal uterine bleeding can be best detected only when the anatomic locale is kept in mind. With this in mind, one might start an examination from the cervix upward.

BLEEDING OF THE CERVIX UTERI

Squamous Cell Carcinoma.—Squamous cell carcinoma is probably the most important diagnosis from the standpoint of the patient. As a rule, when such a cervical carcinoma bleeds frankly, though not excessively, it has already reached the stage of ulceration and, of course, invasion. Postcoital bleeding or occasional spotting on straining may be the first symptom that brings the patient to the examining table. Many of these patients when interrogated in detail may recall a discharge that started weeks or months prior to the presence of the streak of blood. An acquired discharge should never be disregarded in a woman, since we have seen this to be the first subjective symptom of carcinoma of the cervix.

The patient's age is no criterion in cervical carcinoma; the youngest patient we have seen was 18 and the oldest 80 years of age. A careful speculum examination with adequate exposure of the cervix is important. Cervicovaginal smears for cytological study are most informative. Indeed, were they to be taken routinely, the cervical carcinoma might be detected in its very earliest stage—long before bleeding and long before breakthrough of the basement membrane takes place. All cytological reports should be confirmed by biopsy, and a positive smear report read by an experienced cytologist should not go unheeded.

If the cervical carcinoma has reached an advanced stage, a gross lesion that may be granular, raised, papillary, cauliflower, and ulcerated will readily be seen; however, in those patients where the carcinoma is small or very early, only a small erosion-like area or even a "negative" cervix may be encountered. Here the use of

---

Read before the Section on General Practice at the 102nd Annual Session of the American Medical Association, New York, June 3, 1953.
From the gynecologic departments of the Cook County and Grant hospitals, Chicago Medical School, and Cook County Graduate School of Medicine.

Schiller's iodine stain may assist in determining the sites for biopsy. Sites for biopsy should be at the edge of the lesion or at the squamocolumnar junction. Multiple punch biopsies in each of the four quadrants may be done in the office, or a ring excision or cone type of biopsy may be performed in the hospital. Serial sections for microscopic study are often necessary in the early, small lesion.

It is our opinion, at the present writing, that in the young patient in the child-bearing age, who is desirous of having children, a carcinoma in situ can be treated conservatively and the patient allowed to have one or more children. It is here that the repeat cytological examination and biopsy are most helpful for follow-up. Our management of carcinoma in situ in women over 40, or in younger women with their family quota completed, is total hysterectomy. The only time we do radical surgery for carcinoma of the cervix is in the case that does not respond to irradiation. Except for cases of the types mentioned we use radiation therapy.

Adenocarcinoma of the cervical canal must always be kept in mind. Canal curettage cannot be too strongly stressed. A positive Clark test (blood obtained on probing) may be due only to a chronic endocervicitis but, nevertheless, must direct the physician to seek examination of the cells arising from the cervical canal. To this end, cytological smear and a gentle canal scraping are done. At this point, it is well to state that it is our practice in all diagnostic uterine curettages to also do a canal curettage. The material from each source is placed into two separate bottles of a formaldehyde solution (10% Formalin).

Cervical Polyps.—Bleeding from a cervical polyp is usually slight. It may be spotty in nature, occurring after intercourse, examination, straining, or douching. It may also be brisk and may occur at any time. The bleeding takes place because of the congestive ulcerative changes. A cervical polyp is usually benign. Nevertheless, every specimen must be examined histologically and the rest of the cervix carefully screened by cytological and biopsy study.

Many of these polyps are soft and can be easily removed in the office. To be kept in mind are several factors: 1. A concomitant carcinoma of either the cervix or corpus uteri may be present. 2. There may be more than one polyp. 3. What appears as a cervical polyp may arise not from the endocervix but from endometrium. 4. Since many of the simple soft polyps are associated with chronic cervicitis, electrocauterization is very much in order. Also to be emphasized is the possible coexistence of carcinoma of the corpus in cases where the presenting symptom and sign may be only that of bleeding and the presence of a polyp. A diagnostic curettage must be done. Such procedure is comparable to the teaching of inspection of the rectosigmoid in all cases of rectal bleeding in the presence of hemorrhoids to rule out carcinoma of the bowel.

Ectropion, Eversion, and Erosions.—These are very common conditions and give rise to bleeding because of the capillary tufts that appear on the surface of the ectopic columnar-cuboidal epithelium. Ulceration may be present. At times eroded areas may be very granular and papillary, may be friable, and may give rise to even brisk bleeding; however, spotting is the rule. At all times carcinoma of the cervix must be ruled out. Early carcinoma cannot be differentiated grossly from a simple erosion. Cytological and biopsy studies must be made. After carcinoma is ruled out the treatment of choice, in our experience, is electrocauterization followed by dilatations of the canal. This must include a canal cautery in all cases.

Chancre of Cervix.—In very rare instances, a cervical chancre may bleed slightly. The possibility of diagnosis must be kept in mind and followed by a dark field and serologic examinations.

Senile Changes of the Cervix.—The senile cervix can give rise to an atrophic cervix with vascular changes of the superficial vessels, causing bleeding usually in the form of spotting. Treatment must be aimed at local and hormone (estrogen) therapy and systemic use of vitamins, hydrochloric acid, and proper diet.

BLEEDING FROM THE CORPUS UTERI

Corporal bleeding arises from changes in the endometrium owing to vascular interference directly or to interference with the corporal musculature to properly contract. The latter mechanism, if at fault, can allow for excessive bleeding even in the presence of a normal endometrium, or so-called endometrial physiology. Thus intramural infiltration or new growths, regardless of their benignity, may lead to external bleeding.

When the uterine mucosa is primarily involved by an aberration of growth, the immediate cause for bleeding is one of blood supply changes, i. e., congestion, ulceration, poor blood supply, and strangulation. It can thus be seen that bleeding may occur at any time, or perhaps only more excessively during the menstrual period, or only be a prolongation of the menstrual period. The most important corporal bleeding to be kept in mind, just as in the case of the cervix, is that due to carcinoma.

Endometrial Carcinoma.—The endometrial carcinoma, while it may possibly occur at any age, is usually a lesion of the menopause or postmenopausal age. Our youngest patient was 29 and the oldest 78 years of age. Hence, any spotting or bleeding after the menopause must be considered due to adenocarcinoma of the endometrium until proved otherwise. By the same reasoning, any woman who approaches and goes through her menopause with irregular, stormy, or spotty bleeding, that is, any deviation from either the gradual but definite cessation or the sudden ending of menses, may be suspected of having carcinoma of the corpus uteri. Bleeding may only be spotty, but it can be very brisk and continuous even to the point of serious blood loss. The corpus may be normal or only slightly enlarged and very often is freely moveable.

The diagnosis rests on a careful diagnostic curettage, including the cornuisthmic areas. One of the dangers of endometrial biopsy is that often a diagnosis of a "negative" endometrium is obtained although carcinoma is present, the carcinoma being very small, off to a side, and only attainable by the uterine curet. We personally prefer a thorough formal curettage to endometrial biopsy for the diagnosis of cases suspicious of carcinoma of the endometrium. If a corporal carcinoma is shedding cells and/or if an endometrial swabbing is done, a Papanicolaou smear is made. Cells are also found at the cervical os and posterior fornix. It must be remembered that 12 to 20% are missed by this method because of lack of exfoliation.

A picture of adenocarcinoma may be present when the primary source is in the ovary (or even the tube, though quite rarely), with secondary implantation into the endometrium. Careful histological diagnosis is very important in these cases. The first sign of an ovarian carcinoma may occasionally be bleeding from the uterus owing to secondary implantation. Our present treatment of corporal carcinoma is radium irradiation followed by abdominal panhysterectomy, bilateral salpingo-oophorectomy, and then x-ray therapy.

Fibroids.—The submucous fibroid is the usual cause of bleeding in fibroids and need not be very large. Quite frequently other fibroids are present as well, in the wall and under the serosa of the uterus. Bleeding shows itself in the form of excessive and often prolonged flow in the menstrual period. Such repeated menorrhagic episodes may lead to an associated secondary anemia. The fibroid uterus can indeed be very large and the seat of multiple nodules.

In the presence of fibroids there may be associated adnexal masses often thought to be intraligamentary fibroids. These need careful evaluation, for they may be carcinoma of the ovary. In the small uterus, a submucous fibroid can be detected when an irregular filling defect is found on diagnostic curettage or a filling defect on uterosalpingography. Bleeding can also occur owing to interference with proper myometrial contraction due to intramural fibroids.

At times a submucous fibroid is seen prolapsing through the cervical canal. This is usually felt vaginally and seen per speculum. If very large it may even protrude outside the vagina. In these prolapsing fibroids, stasis and ulceration often occur and bleeding is in the form of serosanguinous spotting that may occur at any time. At times a leukometra, pyometra, or hematometra may also be present.

In the treatment of fibroids, age and parity are important considerations. Every opportunity must be given the patient to bear children. We feel that conservative measures include curettage, intravenously and orally administered estrogens, and myomectomy. In the multiparous patient the preferable management in our experience has been abdominal or vaginal hysterectomy; however, in those patients who are poor surgical risks, x-ray examination must be considered.

Adenomyosis.—The presence of endometrial-like structures in the wall of the uterus can interfere with uterine contractility and proper nourishment of the endometrial mucosa. The bleeding is that of a prolonged and/or heavy menstrual period. Associated fibroids may be present occasionally. At times findings of pelvic endometriosis are evident. Acquired dysmenorrhea may be present. The uterus often feels somewhat softened and is usually slightly enlarged and heavy; often it is found in the cul-de-sac. Diagnostic curettage might show a hyperplastic type of endometrium, but menometrorrhagia continues, in spite of the curettage. Our choice of treatment in women in the late thirties and over is hysterectomy. The ovaries are removed, depending on associated pelvic endometriosis and the age of the patient.

The endometrial polyp can be a very annoying cause of excessive uterine bleeding. It may be present in the relatively young patient who has severe menorrhagic periods and whose uterus is of normal size. This patient might have already been subjected to one or more uterine curettages, with no relief of the bleeding. The cavity is often not unusual, and the tip of the curet cannot pick up the polyp. In many cases the polyp has a very broad base, in itself difficult to remove with a curet. A hysterogram will be very helpful in many cases in revealing a filled defect. A direct visualization may also be considered. In contrast to cervical polyps, which are usually benign, the base of the endometrial polyp is often apt to be malignant. The treatment after unsuccessful curettage should be hysterectomy, indeed the only cure possible in many cases.

Tuberculosis of the Endometrium and the Cervix.—Tuberculosis of the endometrium may be discovered quite by accident after a curettage is done for irregular uterine bleeding, spotting, or in the routine endometrial biopsy in a case of sterility. Also cervical tuberculosis lesions may be rather extensive, ulcerate, and bleed. Biopsy again will make the diagnosis. In our cases we use preoperative specific antibiotics, surgery when possible, and postoperative antibiotics and supportive therapy.

Sarcoma of the Uterus.—Sarcomatous degeneration of a preexisting myoma of the uterus may give rise to uterine bleeding. It may be suspected in a rapidly growing uterus containing multiple areas of softening (degeneration). In our experience this occurs in about 0.5 to 1% of all cases of fibroids.

Functional Uterine Bleeding.—During the early menstrual and the childbearing age, when uterine bleeding occurs as a result of nonorganic (uterine) causes, such as a hormonal or metabolic imbalance, or without apparent cause, it can be called functional. It is probably a disturbance of physiological mechanisms. Organic disease must be ruled out before this diagnosis can be made.

Nutritional and vitamin deficiencies must be corrected and nervous and psychogenic factors allayed. Basal metabolic and cholesterol determination may be significant. Conservative observation is justified before doing diagnostic curettage in the younger girl. Thyroid therapy may be tried first. When bleeding is excessive it is often due to anovulatory bleeding. Here one can attempt to establish a cyclic pattern for three consecutive months, usually giving estrogen or diethylstilbestrol for 20 days, 0.5 to 1 mg. daily and then followed by progesterone, 10 mg. three times a day for 10 days. Somehow this may produce normal ovarian function in many of these cases, probably by putting all the concerned organs at rest, namely the pituitary and ovaries. As a rule the follicle stimulating hormone and luteinizing hormone of the pituitary work reciprocally well with the granulosa and thecal elements of the ovary after the "rest." At times a diagnostic curettage must be done, and in some of these patients menstruation will resume.

Not uncommonly the patient is encountered who cannot be relieved of her prolonged or excessive uterine bleeding no matter what form of therapy has been tried. Recently, such patients have responded quite well to the intravenous use of estrogen; 20 mg. (5 cc. aqueous) are given in three doses, six hours apart. The response is very impressive. Bleeding stops almost immediately or within hours, as a rule. Intravenously administered estrogens have also been very useful in the bleeding patient with known organic cause. By slowing the bleeding, it allows blood replacements to act more effectively. The acutely hemorrhaging patient can also be benefited by intravenously administered estrogen, no matter what the underlying cause, by preventing further shock and tiding the patient over until blood flow can be started. The exact mode of operation is not quite understood but may be one of direct action on the coiled arterioles in the endometrium. To prevent withdrawal bleeding, estrogens are continued by mouth in decreasing, staggering doses, or followed by a cyclic regimen of estrogens and progesterone.

Foreign Bodies.—These may be present in either the cervix or corpus. At times a metal pessary left in the cervix works its way into the corpus, engaging itself intramurally. The presence of these foreign bodies leads to infection and necrosis and very commonly spotting of serosaguinopurulent material. The diagnosis may be most puzzling, especially if the foreign body is not immediately identified. To this end roentgenography and vaginohysteroscopy are very helpful. In some cases, the long-standing presence of the foreign body may produce decubitus and even malignant degeneration. Treatment may resort to hysterectomy.

OTHER CAUSES OF UTERINE BLEEDING

In precocious, prepuberty development and onset of menses, a granulosa cell or theca cell tumor (and less commonly, adrenal cortex tumor) of the ovary must be suspected. Rectoabdominal examination (often under anesthesia) may reveal the enlarged ovary. Treatment is surgical removal. In the postmenopausal patient who reestablishes cyclic bleeding one must suspect a granulosa cell tumor of the ovary. Pelvic inflammatory disease may cause derangement and interference with the regulatory mechanism of the endometrium, producing menometrorrhagic periods.

Pregnancy and all its possible complications that cause uterine bleeding will not be fully discussed here. Threatened and incomplete abortion bleeds because of the separation and disruption of blood channels that had previously existed intact between the uterus and the developing conceptus and/or developing placenta. Likewise, postpartum retained placental tissue may cause frank excessive beeding.

There are many other causes for abnormal uterine bleeding, which do not arise from an abnormality of the uterus per se but rather from the influence from without. One might list such conditions as endometriosis, retrodisplacement of the uterus, pelvic stasis, nonestrogen producing tumors of the ovary, retrograde bleeding from tubal disease, and ectopic pregnancy. One must, of course, rule out vaginal bleeding that does not arise from the uterus but rather from the external genitalia, namely, the vulva, urethra, and vagina.

SUMMARY AND CONCLUSIONS

Abnormal uterine bleeding must be regarded seriously no matter in what age group this symptom is found. It may be easier to arrive at the cause of bleeding when the anatomicopathological pattern is kept in mind. Above all, carcinomas must be foremost in the differential diagnosis of any abnormal bleeding. Cytological, diagnostic, and fractional curettage and biopsy all have their proper place. Not to be underestimated are the complete and careful history and physical examination, including a careful bimanual, speculum, rectal, and rectovaginal examination. Constitutional causes must always be kept in mind, especially the interference with the blood platelet function and formation accompanied with the blood dyscrasias; certainly thrombocytopenic purpura must be ruled out, regardless of the presence of known existing organic causes for bleeding. Functional uterine bleeding will less frequently be incorrectly labeled if a strict search for organic causes is made. Functional bleeding does exist and is briefly discussed. Other causes as influenced by extraneous disease and pregnancy are listed.

Blood studies should be done in all cases of abnormal uterine bleeding, irrespective of the obvious gynecological disease, to rule out dyscrasia. Erosions of the cervix should not be treated until the diagnosis of carcinoma has been disproved by smear and biopsy. Certainly all women after the late twenties with aberrations in menstruation must be thought of as having possible carcinoma of the corpus.

All patients with cervical polyps who have abnormal bleeding should have a curettage in addition to a polypectomy so as not to overlook a concomitant carcinoma higher up in the uterus. Patients with asymptomatic fibroids who start abnormal bleeding must be thought to have a possible concomitant carcinoma of the cervix or corpus. One must be cognizant of the possibility of the existence of fibroids with concomitant carcinoma of the ovary. This most important combination must be borne in mind especially when asymptomatic fibroids are present. The carcinoma of the ovary may simulate the asymptomatic intraligamentary fibroid. The latter can be watched but should be reevaluated at frequent intervals, in order to rule out carcinoma of the ovary.

Aerial Application of Pesticides.—The aerial method of application of pesticides is one of increasing popularity. In California alone, in 1951, 2,900,000 acres (1,200,000 ha) were treated by aerial application. The reasons are not difficult to appreciate. For grasshopper control, it took two men with a ground sprayer one day to cover 100 acres (40 ha), whereas the same treatment can be applied over 1,000 acres (400 ha) by two men in 12 minutes in an aircraft. It is obvious, therefore, that more attention should be paid to the proper protection of pilots applying poisonous chemicals from aircraft. According to the Civil Aeronautics Administration (CAA) of the USA, 1,383 agricultural flying accidents occurred in the period 1948-51. An analysis showed that in only 11 of these cases could the cause of the accident be definitely attributed to the effect of a chemical or other noxious agent. . . . The CAA believes that lesser degrees of toxic action "may be partly or wholly responsible for a much greater number of agricultural flying accidents." . . . A surprising number of incidents are reported in which the pilot becomes covered in dust or spray during the operation; this suggests the need for a properly designed aircraft. At present, progress is being made towards this end by a collaborative effort between the United States Department of Agriculture, the CAA, and an aircraft construction company.—J. M. Barnes, M.D., Toxic Hazards of Certain Pesticides to Man, *Bulletin of World Health Organization*, No. 4, 1953.

ANTIBIOTICS IN DISEASES OF THE BILIARY TRACT

Jerry Zaslow, M.D., Philadelphia

As new antibiotic or chemotherapeutic agents have been introduced into the therapeutic armamentarium, many of them have been used in the treatment of biliary tract disease. Improvement observed following the use of these drugs has often been attributed to them. This has been due to the fact that each of these drugs, in the course of pharmacological observations, has been shown to be excreted into the normal biliary tract of lower animals or humans. Until I began to study the excretion and concentration of antibiotic and chemotherapeutic agents in the abnormal human biliary tract, no one had approached the problem from that aspect. Since that time I have studied the excretion and concentration of the sulfonamides, penicillin, streptomycin, aureomycin, and, more recently, oxytetracycline (Terramycin). As a result of these investigations it became apparent that the excretion and concentration in the abnormal biliary tract was entirely different from that in the normal, and that various conditions were necessary for the excretion of those drugs in any therapeutic concentration. The results of those investigation either have been previously reported [1] or will be reported in the very near future.[2]

In the presence of normal liver function and an unobstructed biliary tract each of the agents studied was excreted in high concentration into the extrahepatic biliary tract. In the presence of either impaired liver function or active common duct obstruction, or a combination of both, the drugs either were not excreted at all or were excreted in small amounts, depending on the degree of liver damage or common duct obstruction. When the cystic duct was patent and the drugs were excreted from the liver into the bile ducts, they appeared in the gallbladder bile and remained there for long periods of time. However, when the cystic duct was obstructed, none of the agents studied entered the gallbladder lumen; this was true whether or not the organ was acutely inflamed. It was concluded as a result of these studies that the patency of the cystic duct was the most important factor concerned with the drugs entering the gallbladder lumen. Acute inflammation of the organ did not alter the mode of entrance.

In order to determine whether these experimental findings were useful when applied in the treatment of biliary tract infections, a clinical study was undertaken during the five year period from 1947 to 1951, inclusive. Every other patient admitted to the hospital with the signs and symptoms of acute cholecystitis, other disease such as pancreatitis, duodenal ulcer, or hepatitis having been ruled out, was immediately placed on a regimen consisting of feedings given intravenously, drugs to relieve pain, and gastric suction if there was much vomiting or belching. Nothing was given orally. Every other patient admitted with the same diagnosis was treated in a similar manner, except that an antibiotic was also administered. Only those cases in which acute obstructive cholecystitis proved to be present at operation were included in the survey. A similar program was followed for patients with common bile duct obstruction, often with associated clinical evidence of cholangitis and/or hepatitis, although these patients were encouraged to eat well.

RESULTS OF THE CLINICAL STUDY

Patients with Acute Cholecystitis (Table 1).—There were 171 cases of proved acute cholecystitis. It was observed that in the group of patients with a milder clinical form of the disease unassociated with severe systemic reaction (109 patients) the response to the regimen omitting antibiotics was often prompt and complete, as demonstrated by the return of the leukocyte count and temperature to normal, and by the subsidence of local tenderness and rigidity; however, a mass in the upper abdomen often persisted. There was little appreciable difference in response when an antibiotic was given. What improvement was noted could not be attributed to the antibiotics.

There was a marked difference in response to antibiotics in that group of patients where there was a severe systemic reaction to the local disease (62 patients). In those patients in this group who did not receive any antibiotic (31 patients) the symptoms and signs were slow to respond to ordinary medical measures, or did not respond at all. Five of those patients appeared to become worse. They were then given an antibiotic, and treatment without antibiotics was considered to have failed. The response of the group of patients with marked systemic reaction to the local disease treated with antibiotics was often quite dramatic. In many the temperature promptly returned to normal, chills, if present, disappeared, and the leukocyte count dropped. On the other hand, although the local tenderness and rigidity decreased, a mass in the right upper quadrant ofter persisted, and subsidence, if it occurred at all, was very slow. This was an interesting observation, indicating that the local process was little or not at all affected. However, because of the improvement in the patient's general systemic condition, emergency surgery could usually be deferred. In two patients in the entire series, in spite of large doses of antibiotics, there was local or systemic progression of the disease, making emergency surgery necessary. In all others (169 patients) operation was performed electively 7 to 14 days after admission to the hospital.

When these patients with acute cholecystitis were subjected to operation, it was observed by both the operator

and the pathologist that they were unable to determine, on the basis of the local pathological changes, in which patient an antibiotic had been used in the preoperative period. Empyema of the gallbladder was seen both in those who did and in those who did not receive antibiotics (16% in each group). In some patients the gallbladder had perforated locally or into a walled-off area in the liver, or was densely surrounded by omentum and was adherent to adjacent colon or duodenum (27% of all patients). This observation also bore out the fact that in many patients it was impossible to determine from the clinical picture what the local pathological process would be when operation was performed. Often a patient admitted to the hospital and responding within 6 to 12 hours to ordinary medical measures excluding antibiotics was found to have an empyema with or without local perforation. This was also true in those who received antibiotics.

TABLE 1.—*Results of Study of 171 Patients with Acute Cholecystitis*

Condition of Patient	No. of Patients	Clinical Response	No. of Patients with Empyema
Mild systemic reaction * No antibiotics given on admission	55 (mass noted in 17)	Good No emergency operation (mass persisted in 6)	10
Mild systemic reaction * Antibiotics given on admission	54 (mass noted in 12)	Good No emergency operation (mass persisted in 9)	8
Severe systemic reaction † No antibiotics given on admission	31 (mass noted in 12)	26 improved systemically (mass persisted in 4) 5 became worse and then were given one of the antibiotics, with excellent systemic response; no emergency operations were done	4
Severe systemic reaction † Antibiotics given on admission	31 (mass noted in 14)	Excellent systemic response in 29 (mass persisted in 7); no emergency operations were done. 2 patients became worse and were given emergency surgery	5

* Leukocyte count under 18,000 blood cells per cubic milliliter, temperature under 101 F, and pulse rate usually under 100 per minute.

† Leukocyte count over 18,000 cells per cubic milliliter, a temperature over 101 F, and pulse rate usually over 100 per minute.

Patients with Common Duct Obstruction and Cholangitis (Table 2).—The problem with regard to common bile duct obstruction with cholangitis is quite similar to that described. In many patients with obstruction pain and jaundice were the only symptoms present. In others these were associated with chills, fever, drenching sweats, and high leukocytosis. The administration of antibiotics to those with simple obstruction did not appear to affect the severity of the icterus or the pain; many of them had subsidence of symptoms without any active treatment.

As to the group with associated clinical evidence of cholangitis, many had complete subsidence of all systemic symptoms without any antibiotic treatment. On the other hand, in some of the patients the disease appeared to become progressively more severe. When one of the antibiotics was given to this group of patients, the response was often dramatic; within 24 to 48 hours all systemic symptoms disappeared, with the jaundice becoming less intense in some. On the whole, in that group of patients with clinical evidence of cholangitis of moderate or severe degree who received antibiotics immediately after admission to the hospital the systemic response was excellent.

When surgery was performed on patients with ductal obstruction, the incidence of positive bile cultures was 85.7% for the group treated without antibiotics and 82% for the group treated with antibiotics.

COMMENT

Acute Cholecystitis.—It is generally recognized that many patients with acute obstructive calculous cholecystitis will have spontaneous remission of the disease. Others will have progression of the disease with empyema or rupture, either locally or into the general peritoneal cavity. In the recent literature there have been a few reports indicating that some of the antibiotics have brought about improvement of this disease. In view of what has been stated in the preceding paragraphs, these reports should be evaluated more critically. As a result of the findings of this investigation, it appears that the antibiotics do not affect the local pathological changes. This has been reported by others.[3] On the other hand, the antibiotics in many cases did often promptly relieve systemic symptoms within a few hours after their administration. In several test cases when the drug was stopped the symptoms recurred, only to subside again when the drug was once again given. It appears that in the management of a patient with acute cholecystitis the antibiotics may be particularly useful when there is a severe systemic reaction to the local disease.[4] In the presulfonamide era many patients with acute cholecystitis who had systemic symptoms were often operated on as emergencies. The mortality figures of that day were mainly the mortality figures of that group. However, since the local pathological process is apparently not affected, the physician must not be deluded into a sense of false security in any particular case. It is not within the province of this report to judge the value of immediate as against delayed sur-

TABLE 2.—*Results of Study of Eighty-Four Patients with Common Duct Obstruction*

Condition of Patient	No. of Patients	Clinical Response	*No. of Patients with Positive Bile Cultures*
No clinical cholangitis * No antibiotics given on admission	13	No effect	7
No clinical cholangitis * Antibiotics given on admission	13	No effect	5
Clinical cholangitis † No antibiotics given on admission	29	14 improved,‡ and 15 became worse and were then given antibiotics §	29
Clinical cholangitis † Antibiotics given on admission	29	27 improved, and 2 did not improve	29

* *No obvious signs or symptoms of infection, such as chills, fever, or leukocytosis.*

† Jaundice, chills, fever, and/or leukocytosis.

‡ Systemic symptoms subsided within 24 to 48 hours.

§ Of these 15 patients, 12 had a prompt *response to* antibiotics.

gery in the management of acute cholecystitis. It suffices to say that in any case where the local process continues all agree that operation is indicated. I would suggest the following measures be followed for all patients with acute cholecystitis: (1) absolute bed rest; (2) administration of nothing by mouth; (3) gastric suction if there is much vomiting or belching; (4) administration of meperidine (Demerol) and atropine to relieve pain; (5) administration of fluids and vitamins intravenously; (6) omission of antibiotics for those patients who do not have a marked systemic reaction (this would prevent the occasional anaphylactic or toxic effect of the drug), but administration of antibiotics to patients who do have marked systemic reaction or who do not respond readily to the above measures; (7) early operation when deemed necessary owing to lack of response of systemic symptoms and progress of the local disease.

It would appear that the antibiotics might prove helpful in the management of gallbladder disease when the cystic duct is not obstructed. This includes the occasional case of acute noncalculous cholecystitis (about 5% of all cases of acute cholecystitis) and those of chronic cholecystitis without cystic duct obstruction. I have had several patients with all the signs and symptoms of acute cholecystitis associated with severe systemic reaction in whom other disease was ruled out and who responded promptly to antibiotics, and in whom subsequent cholecystograms and biliary drainages were unable to prove the presence of either calculi or bacteria in the biliary tract. Whether these were cases of acute noncalculous cholecystitis cured by the antibiotics was never definitely established; the evidence was very suggestive. Several years ago I operated on a patient with acute cholecystitis in the days when penicillin and streptomycin were used. Since that patient was sensitive to both drugs as well as to the sulfonamides, he was given neither and was operated on as an emergency. No calculi were found. Cultures of the gallbladder wall and bile showed Streptococcus hemolyticus. This patient may well have responded to one of these drugs had it been considered safe to use them. In three other cases of noncalculous cholecystitis (two cases of Brucella melitensis cholecystitis and one of streptococcic cholecystitis) the administered antibiotic was useful only while it was being given. When the drug was stopped, the disease recurred, both locally and systemically.[5] After the gallbladder was removed, there was no longer any recurrence. This may have been due to the fact that the organisms harbor in the wall of the gallbladder and are most difficult to eradicate in this location. Whether these drugs will prove useful in the management of cases of typhoid cholecystitis is uncertain. As to the group of patients with nonobstructive calculous cholecystitis, I am unable to see how the antibiotics can be of any permanent value, since the pathological changes of acute obstructive cholecystitis depend primarily not on infection but rather on obstruction of the cystic duct with secondary distention of the organ. In addition, since the organisms when present often are buried deep in the wall of the gallbladder, drug therapy is most uncertain in reaching them.[6]

Common Duct Obstruction with Cholangitis.—All who have had any experience with cases of cholangitis are well aware of the fact that this disease is often associated with spontaneous remissions and exacerbations. This is particularly true when the causative agent, such as mechanical obstruction from stone, stricture, or tumor, is not removed. In view of this observation it is most difficult to evaluate the effectiveness of any drug given to "sterilize" the biliary tract in such cases. Numerous reports in the literature have attested to the fact that one or another drug was responsible for curing a patient with cholangitis. As a result of the basic excretion studies carried out and previously reported,[7] it would appear that the antibiotics often prove useless when they are most needed. In patients with biliary tract obstruction and infection proximal to the obstruction it has been shown that the agents do not reach the biliary tree until the obstruction is removed, provided that the liver damage is not severe enough to interfere with excretion of the drug. On the other hand, since the liver is so rich in its blood supply, it can be supposed that the drug would reach it in high concentration and may in this way help resist the ascent of organisms into the liver itself. From the clinical study presented here it appears that this does happen. In many patients with obstructive jaundice and cholangitis the antibiotics did improve the general condition of the patient, so that chills, fever, and, in some cases, even jaundice would abate. In this way the patients could be more carefully and deliberately prepared for operation. It would appear that the offending organisms produce much of their systemic effects as a result of invasion of the liver and subsequently the blood stream. In some cases the drug appears to arrest the organisms at the hepatic level, converting the disease from a systemic to a local one.

In the postoperative period the antibiotics are useful locally in the bile ducts, since, when the obstruction is overcome, these agents are excreted in high concentration as the liver function improves. In this manner they aid the natural antibacterial action of free flowing bile. In cases of infection of the liver secondary to bloodborne organisms or to direct lymphatic spread the antibiotics are useful.[8] On several occasions cases of pyelophlebitis of the portal vein cured by one of these agents have been reported.

No mention has been made as to whether one antibiotic was more effective than another. An attempt was made to do this; however, this was such a difficult thing to interpret, or even to tabulate, that it has not been included in this paper. In any particular patient the ideal drug would be the one that is shown to inhibit the organisms in his biliary tract. However, since such cultures cannot be made in the preoperative period, the next best choice is a wide-spectrum antibiotic.[9]

SUMMARY

The most important factor affecting the entrance of certain drugs into the gallbladder lumen is the patency of the cystic duct. Acute inflammation of the gallbladder does not alter the mode of entrance of these drugs. In the presence of an unobstructed common bile duct and normal liver function the drugs are excreted from the liver into the biliary tract in high concentration. In the presence of an actively obstructed common bile duct or impaired liver function the drugs are excreted either not at all or in very small concentrations. When obstruction is overcome and liver function improves, the drug is again excreted in high concentration.

The local pathological changes of acute obstructive calculous cholecystitis are not affected by the therapeutic agents studied. In an occasional case acute noncalculous cholecystitis may be cured by one of these agents. In the usual mild case of acute obstructive calculous cholecystitis the clinical course is not affected by the administration of these drugs. In the gravely ill patient with acute obstructive cholecystitis the systemic symptoms are often relieved by the administration of these drugs; the local process appears to be unaffected. The percentage of cases of acute obstructive cholecystitis with empyema or perforation is the same, whether or not the drugs are used. The drugs should be used in cases of acute cholecystitis with systemic manifestations in order to better prepare patients for operation. The availability of these drugs should not alter the indications for operation in acute cholecystitis.

In patients with obstructive jaundice the drugs do not overcome any active local infection as long as the obstruction persists. When obstruction is relieved, the drugs are excreted in high concentration and may be expected to aid the natural healing processes. During active common bile duct obstruction the drugs should be given to protect the liver from ascending infection. During active common bile duct obstruction the drugs often do relieve any associated systemic symptoms, making these patients better operative risks. The availability of these drugs should not alter the indications for operation in cases of obstructive jaundice with cholangitis. They should be used only as adjuncts both in the preoperative and postoperative periods.

RENAL FUNCTION DURING GENERAL ANESTHESIA AND OPERATION

E. M. Papper, M.D., New York

Interest in renal function during anesthesia and operation and in the postoperative period has increased greatly in recent years. There has been an intensive effort to gain further knowledge about renal activity in surgical patients, with a greater appreciation of the subtle physiological changes that occur during and after operation. Renal function was not previously emphasized in care of surgical patients because of pressing demands for study of cardiovascular function and respiration, which are immediate problems in every surgical patient. Although not so apparent, the influence of the kidney on the ultimate success of surgical procedures is no less striking.

This paper reviews briefly some of the aspects of renal function during anesthesia and surgery. Perhaps it is not generally realized that the kidney is a circulatory organ of considerable importance; it normally accommodates approximately 25% of the total cardiac output. The kidney undoubtedly has an important role in circulatory adjustments during anesthesia and operation because of the widespread cardiovascular changes that occur during anesthesia in response to stimuli designed to maintain arterial pressure, cardiac output, and adequate blood flow to the vulnerable tissues of the brain and the heart. It will be useful to examine the nature of renal participation in this homeostatic circulatory response.

It has long been known that urine formation is diminished during and after anesthesia. This is associated with retention of salt in the postoperative period and inability of the body to tolerate certain types of salt loads. There appear to be acute persistent derangements in distribution, volume, and composition of body fluids during the period of convalescence.[1] Since the kidney is so directly involved in selective secretion and retention of water and electrolytes it is of interest to study the influence of anesthesia and operation on kidney function from this standpoint.

Studies over the last few years suggest that serious disturbances in normal acid-base balance may occur during anesthesia and operation and sometimes in the postoperative period. So far as is known, the changes in acid-base control are largely respiratory in origin.[2] These originate chiefly in the factors associated with hypoventilation and, therefore, impaired excretion of carbon dioxide, with subsequent development of respiratory acidosis. It has not been adequately appreciated that the kidney, which is the other important organ of acid-base control, under normal conditions can effect sufficient compensation for this type of respiratory dysfunction. Whether the kidney is able to do so during anesthesia is open to question. There are, unfortunately, insufficient data on this question, but the possibility of renal dysfunction under these conditions cannot be ignored.

Finally, interest is directed to the kidney because of the infrequent but serious total disruption of renal function in the postoperative period. This has been attributed to insufficient perfusion of blood through the kidney, with consequent anoxia of renal tissues. The kidney has been alleged to be extraordinarily sensitive to oxygen lack under these conditions; an otherwise satisfactory

anesthesia and operation may result in either fatal anuria or stormy convalescence with a lower nephron nephrosis syndrome. Anesthesia may have some bearing upon the development of this syndrome.

EFFECT OF ANESTHESIA ON DISCRETE RENAL FUNCTIONS

It appears logical, therefore, to investigate the nature of changes in discrete renal functions during anesthesia by studies of glomerular filtration, renal blood flow, and urinary excretion of water and electrolytes. In 1943, Coller and his associates [3] studied the influence of ether and cyclopropane on glomerular filtration and renal plasma flow. They found no essential change in these functions with ether anesthesia but observed depression of glomerular filtration and a variable effect on renal plasma flow with cyclopropane. This relative lack of effect of anesthesia agents on glomerular filtration and renal plasma flow has not been corroborated by subsequent studies. From other observations the absence of disturbances in renal function during anesthesia found by Coller and his associates may be explained by the time during the course of anesthesia at which observations were made. Control measurements were made prior to the establishment of anesthesia, and the changes associated with anesthesia were measured at the end of operation. Studies by Habif and others [4] indicate that recovery in glomerular filtration and renal plasma flow changes occurs at the termination of anesthesia.

Another variable that may influence these observations concerns depth of anesthesia. Craig, Visscher, and Houck,[5] found that, in the dog, renal plasma flow, glomerular filtration, and renal tubular activity were not altered significantly during light anesthesia with ether or cyclopropane; however, during deep anesthesia these functions were reduced approximately 50%, which was attributed to neurogenic constriction of afferent renal arterioles. In view of this work it should be pointed out that no studies are available in which the depth of anesthesia was monitored rigidly either by measurement of the concentration of anesthetic agents in the arterial blood or by electroencephalographic control. Thus some of the confusion in observation and interpretation of renal changes may be attributed to the fact that different workers have studied anesthesia at different depths, relying on relatively crude clinical signs.

In 1949, Burnett and his associates [6] also studied the influence of ether and cyclopropane on renal function in man. Depths of anesthesia used were "moderate to light," and the variables of premedication and operation were eliminated by terminating the observations just prior to operation and omitting premedication. With ether anesthesia glomerular filtration decreased an average of 21% and tended to improve as anesthesia progressed. Renal plasma flow fell an average of 39%, and the filtration fraction rose an average of 25%. Urine flow during anesthesia decreased 51% because of increased tubular reabsorption of water as well as a decrease in glomerular filtration and renal plasma flow. During cyclopropane anesthesia the changes were similar but increased in intensity. Glomerular filtration decreased an average of 31%; renal plasma flow fell an average of 52%; and the filtration fraction rose 35%. The changes in renal function were clear, significant, and marked; however, the influence of ether on renal functional changes was less marked.

The influence of the barbiturates on these phases of renal function has not been extensively studied. In 1943 Corcoran and Page [7] pointed out that pentobarbital sodium in doses of 30 mg. per kilogram of body weight given to a dog intraperitoneally does not significantly alter glomerular filtration or renal plasma flow. Glauser and Selkurt [8] found that barbital sodium and pentobarbital sodium had no apparent effect upon glomerular filtration in a dog during a 5 to 6 hour period, Renal plasma flow decreased about 18% during the same interval; this change was not thought to be significant.

Another factor of importance is the state of hydration of the patient prior to measurement of renal functions. Breed and Baxter [9] point out that the surgical patient may be in various stages of dehydration and starvation preoperatively. These conditions undoubtedly influence subsequent studies and should be considered in comparing functional values in the surgical patient with those observed in normal persons under nonsurgical conditions.

STUDY OF 34 PATIENTS

In 1951, Habif and his associates [4] reported a study of 34 patients subjected to a variety of major surgical procedures. Studies of glomerular infiltration, renal plasma flow, urine excretion, and excretion of sodium, potassium, and chloride were made. Agents studied were the premedicant drugs meperidine, morphine, and atropine, and the anesthetic agents cyclopropane, ether, and the combination of thiopental sodium and nitrous oxide and oxygen. Insofar as possible, the depth of anesthesia was kept at the second plane of surgical anesthesia as judged by clinical signs.

The effect of meperidine (100 mg. doses in the average adult) was a reduction in glomerular filtration ranging from 21% to 45% below the control value. Renal plasma flow also decreased 24% to 50%. There was an associated slight rise in filtration fraction. These changes were not interpreted as caused by the slight, relatively inconstant fall in blood pressure seen subsequent to the use of this drug, but as evidence of intrarenal vasoconstriction. Similar but less marked changes in these two functions were observed with the use of 10 mg. of morphine subcutaneously. The most striking change was a sharp decrease in urine flow with use of meperidine. This decrease in water output was associated with increased urinary concentrations of sodium, potassium, and chloride. Despite these changes in concentration, total output of electrolytes actually diminished. Output of potassium was nearly always reduced to the same extent as glomerular filtration. It was inferred that potassium reabsorption remained relatively unchanged during the influence of meperidine but that there was an increase in tubular reabsorption of water, sodium, and chloride relative to glomerular filtration. Atropine in doses of 0.5 mg. had no apparent effect on renal function.

In 11 patients changes in renal function were observed during cyclopropane anesthesia and major surgical procedures uncomplicated by shock or hemorrhage. Cyclopropane produced a definite decrease in glomerular filtration, averaging 55%. Renal plasma flow was reduced approximately 70%. These changes occurred immediately or shortly after induction of anesthesia, were associated with a rise in filtration fraction, and were interpreted as evidence of marked intrarenal vasoconstriction affecting both afferent and efferent arterioles. The surgical procedure itself had no further influence on renal function. In fact, as operation progressed, glomerular filtration and renal plasma flow tended to return toward normal. Urine output was remarkably reduced and in some instances ceased entirely. Changes in urinary potassium excretion were variable; however, almost without exception the output of sodium and chloride was remarkably reduced. These electrolyte changes were interpreted as due to a relative increase in tubular reabsorption of water and electrolytes. When anesthesia was discontinued all measured functions returned quickly to, or nearly to, the control levels. This was observed despite an occasional reduction in blood pressure (cyclopropane shock) following termination of anesthesia. There was, however, no evidence of reactive hyperemia in the kidneys. As glomerular filtration was restored to normal, urine output and excretion of electrolytes increased, with no tendency to rise above preanesthetic control levels.

During ether anesthesia there was a 40% reduction in glomerular filtration and 54% decrease in renal plasma flow. These changes were similar to those observed with cyclopropane, although the response was not quite so marked. The observations of Burnett and his associates [6] were, therefore, corroborated. During ether anesthesia there was also increased reabsorption of water, sodium, and chloride, relative to filtration. Changes in renal function observed during thiopental and nitrous oxide-oxygen anesthesia were similar to those observed with cyclopropane and ether.[4]

PHYSIOLOGICAL INTERPRETATIONS

It is necessary, therefore, to examine all these data in order to define and interpret the nature of renal functional changes during anesthesia and operation. Anesthetic agents that produce loss of consciousness apparently have a profound, reasonably consistent, and relatively nonspecific effect on output of urine, excretion of electrolytes, and on certain circulatory changes within the kidney. This is true if the depth of the anesthesia is reasonable and if observations are made during administration of anesthesia, rather than at its termination. Hemodynamic changes in the kidney are those of vasoconstriction, which persists only as long as the patient is unconscious with general anesthetic agents. Because of the reduction in glomerular filtration as well as renal plasma flow, there is probably both afferent and efferent arteriolar constriction in the kidney; in fact, this vasoconstrictor response in the kidney circulation is also associated with vasoconstriction in the splanchnic circulation.[4] Reduction in blood flow is approximately 50% through these two major peripheral circulatory components. The impact of this marked redistribution of blood flow during anesthesia must be great; its significance in terms of physiological activity during anesthesia and operation remains for future interpretation. At present, the cause of these vascular adjustments is unknown; however, it appears reasonable to assume that trauma of operation has no influence, since the changes occur during anesthesia without operation and tend to decrease as operation progresses, provided there is no shock or hemorrhage. Renal vascular changes are also rapidly reversible after termination of anesthesia, which suggests that there is probably little significant direct action of drugs on the renal circulation. It is unlikely, for example, that ether could be eliminated from the tissues within a period of 10 to 20 minutes in sufficient concentration to permit reversal of the renal changes described. Thiopental in this period of time (10 to 20 minutes) remains almost unchanged with respect to tissue and plasma concentration.[10] Renal hemodynamic changes observed during anesthesia resemble changes seen with a variety of clinical situations such as congestive heart failure, violent exercise, pain, chronic anemia, and shock. In these circumstances intrarenal vasoconstriction may serve a useful purpose in diverting blood temporarily from organs relatively resistant to anoxia to more vulnerable tissues such as the brain and heart. Even if this response during anesthesia can be accepted as a homeostatic influence of stress, the mechanism of production of these changes is obscure. Changes in arterial pressure do not account in general for the renal changes. Autonomic interruption by high spinal anesthesia or sympathectomy does not alter the responses described during cyclopropane, ether, or thiopental, nitrous oxide, and oxygen anesthesia.[11]

Elaboration of antidiuretic hormone by the posterior pituitary does not account completely for the urinary changes during general anesthesia, since electrolyte excretion is also profoundly disturbed. Habif and his associates [4] attribute electrolyte changes to the increase in tubular reabsorption resulting from a decrease in glomerular filtration, which in turn is the result of intrarenal vasoconstriction.

There is also the question whether the profound renal functional changes described are responsible for failure of the kidneys to make appropriate adjustments to administration of water and salt in the postoperative period. The studies of Habif and his associates [4] indicate that renal functional changes are temporary and reversible. It is reasonable to assume that postoperative changes are not caused by a defect in glomerular filtration; however, it is possible that the renal tubules have been conditioned in some manner by anesthesia or operation or both, so that they do not function adequately with regard to water and salt loads in the postoperative period. Corroboration of this interpretation is presented by Ariel and Miller,[12] who showed that renal plasma flow was essentially normal in the postoperative period, and, in fact, glomerular filtration actually increased an average of 12.7%, with an associated increase in filtration fraction of 17.4%. The authors concluded that, in the absence of shock and hemorrhage, postoperative water and electrolyte alterations are not the result of kidney dysfunction. Moyer [13] also stated that the anesthetic agent per se is not implicated in postoperative derangements of urine formation and electrolyte control. He believes these changes are probably due to distributional shifts of body fluids and afferent stimuli from the operative area.

VENOUS CONGESTION, ANOXIA, AND HYPOTENSION

Another point of interest is the effect of chronic peripheral venous congestion on renal sodium excretion. Venous congestion or dilatation during anesthesia is not uncommon; either condition may be associated with increases in venous pressure. This effect on the veins is not clearly understood, but it may be caused by subtle increases in resistance to breathing, unrecognized respiratory obstruction, and venodilatation from the autonomic effects of anesthetic agents. Frieden and his associates [14] showed in the dog that the kidney may retain abnormal amounts of sodium by increased tubular reabsorption during venous congestion and that this renal mechanism is not necessarily accompanied by a fall in glomerular filtration or renal plasma flow. This change apparently occurs with a generalized elevation of venous pressure and does not necessarily involve specific increases of venous pressure in renal circulation.

The influence of anoxia on renal function is important during anesthesia, because anoxia may occur at any time; in fact, reduction in renal plasma flow may cause relative renal anoxia. In studies on unanesthetized dogs and men, Axelrod and Pitts [15] found no significant effect on renal tubular function or glomerular filtration during anoxia induced by inhalation of gas mixtures deficient in oxygen. They also pointed out that in moderate hypoxia there was no major change in oxygen consumption in the kidney. No satisfactory data are available defining the influence of anoxia on renal functional activity during anesthesia.

Increasing use of induced hypotension with autonomic ganglionic blocking agents during anesthesia presents the problem of the influence of this type of anesthetic management on renal function. Miles and his associates [16] reported the effects of hypotension produced by pentamethonium bromide during inhalation anesthesia with ether and cyclopropane. Both ether and cyclopropane caused a fall in renal plasma flow and glomerular filtration similar to that reported by others. After induction of hypotension with pentamethonium bromide there was no further change in renal blood flow. A slight increase in glomerular filtration was observed during induced hypotension. Miles and his associates interpret the fact that renal plasma flow was well maintained in spite of considerable reduction in arterial pressure as indicative of a substantial renal vasodilatation. They believe that the mechanism for maintenance of a relatively constant renal plasma flow is more directly associated with the inherent capacity of these vessels to adjust their caliber than it is with blockade of sympathetic impulses to the renal vessels by pentamethonium bromide. The authors point out, however, that renal blood flow was maintained during hypotension in healthy patients undergoing minor surgery. It is by no means certain that the same changes would occur under less favorable conditions.

SUMMARY AND CONCLUSIONS

In interpretation of these data on the influence of general anesthetic agents on renal function, it is clear that general anesthesia produces a stereotyped response in the kidney, depending somewhat on depth of anesthesia; the greater the depth, the more profound the changes. These stereotyped changes are a striking intrarenal vasoconstriction associated with a fall in glomerular filtration and reduction in urinary concentration and excretion of electrolytes and water. There appears to be a relative increase in renal tubular reabsorption of both electrolytes and water. The changes are similar to those seen with various lesions and physiological alterations that may be considered stressful. Operation itself, in the absence of shock and hemorrhage, has little effect on renal function that can not be accounted for by the effect of anesthetic agents. It is probable that renal dysfunction in the postoperative period is due not directly to influence of the anesthetic agent during operation but to other factors involving responses from the wound and shifts in body fluids. The anesthetic agent itself may affect the renal tubules so that they are unable to manage increased water and salt loads in postoperative parenteral fluid treatment.

Renal Tumors.—The diagnostic methods now available for recognition of renal tumor are noted for their accuracy and rarely fail if properly applied and the results correctly interpreted. It appears, therefore, that if a number of asymptomatic lesions are to be diagnosed during a stage when nephrectomy may effect a cure, more routine studies of the urinary tract will have to be done than are currently being done. Rarely does a general physical examination fail to include a roentgenogram of the chest, and few pulmonary lesions are encountered which are of more importance than renal tumors. The ease with which excretory urography is carried out and the information gained from it have largely eliminated the objectionable features of studying the urinary tract which formerly existed. As already indicated, it does not within itself suffice to diagnose space-occupying masses of the renal parenchyma but in the presence of good renal function it will indicate variations from the normal that suggest the necessity for other supplementary studies. It is not suggested that routine study of the urinary tract be done on every patient, but tumors of the renal parenchyma are found largely in those between the ages of 40 and 55 years, and it seems reasonable to suggest that this group be subjected to the same careful consideration of the urinary tract that is given the chest, the gastrointestinal tract and other systems.—Edgar Burns, M.D., Clinical Diagnosis of Tumors of Adult Renal Parenchyma, *The Journal of Urology*, July, 1953.

THE SOCIOPSYCHOLOGICAL TREATMENT OF EPILEPSY

William G. Lennox, M.D.
and
Charles H. Markham, M.D., Boston

Epilepsy is no longer inscrutable; its control is no longer in the state of wishful thinking. The electroencephalogram, new medicaments, and fresh surgical techniques promise recovery to countless victims of the disease and to their physicians. However, there are obstructions as formidable as the seizure barriers already passed. The good physician cannot abandon his charges at this point, but he must study these obstacles and assist in surmounting them. He must match modern drug and surgical therapy with practical sociopsychological therapy. The good physician is concerned not only with turbulent brain waves but with disturbed emotions and with social injustice, for the epileptic is not just a nerve-muscle preparation; he is a person, in health an integrated combination of the physical, the mental, the social, and the spiritual. Disruption of any part can cause or aggravate illness.

EMOTIONAL PROBLEMS

Epilepsy is not characterized by a continuous prolonged condition but a recurrent spasmodic crisis. A healthy person, happy and productive, is suddenly bereft of awareness, of control of body and mind and becomes a fearful spectacle to all who behold him. He wonders about the reasons for these attacks and whether he will finally be institutionalized. Emotional and social dislocations represent the debris of successive inundations. Though present in nearly all epileptics, they differ widely in substance and degree.

Psychological and emotional consequences of seizures, such as anxiety, uncertainty, and fear, may accompany any serious disease; however, for the victim of other illnesses there is public sympathy and support and for the epileptic only, public dislike and rejection. The emotions of the epileptic then include shame, depression, bitterness, secrecy, and deception. In a vicious circle, consequence becomes cause and anxiety aroused by social mistreatment can precipitate some of the seizures. These emotional difficulties are on the conscious level and fully understandable (and treatable) by an understanding physician, whatever his specialty.

Emotional perturbations may accentuate but do not initiate epilepsy. If they originate the illness, it is not epilepsy but hysteria. Epilepsy is due to physiological, not psychological, disturbances. The brain waves are evidence of this. Nevertheless, some Freudians insist that a devastating convulsion is the person's unconscious attempt to retreat to the comfortable cavern of the uterus. They believe that hope of release from this "womb sickness" lies in protracted and expensive delving into childhood experiences and frustrations. We believe this view is erroneous and that the practice of psychoanalysis, sans medicine, for the person with uncomplicated epilepsy is malpractice. True, some epileptics, in company with many persons who are physically normal, have aberrations of thought or of personality that require the aid of the mind specialist; however, this is afield from the restricted subject of epilepsy.

Psychic seizures relate to the temporal lobes. Certain hallucinations, automatisms, and amnesias, some with criminal content, may be epileptic seizures. The diagnosis is supported if spikes from a temporal lobe appear in the electroencephalogram. The epileptic may have mood or personality changes that accompany the seizure state. After successful drug or surgical treatment of the epilepsy, these changes may vanish.

The restrictions, justified and unjustified, that are placed on the person's activities seriously affect his prospects and accomplishments; however, the larger injury is not apparent. Repeated rebuffs lead to timidity or to irritations and anger ending in aggressiveness and antisocial behavior. But the most grievous injury is to the person's spirit, which assumes the furtive fear of the hunted, the guilt of the criminal, the sense of uncleanness of the patient with leprosy. Decay of confidence, ambition, and hope may follow.

The emotional reactions aroused by epilepsy are not confined to the person seized. They are communicated to his family and close friends, often in exaggerated form. Epilepsy is then the immediate concern not of 800,000 but of at least 4 million persons. The pressure of anxiety and shame does not become eased through shared experience, because the fact of seizures, the family feels, must be kept a secret. Shamed secrecy maintained over the years is a corroding influence. Shakespeare in "Hamlet" had a phrase for it, "But like the owner of a foul disease, to keep it from divulging lets it feed even on the pith of life." The epileptic knows that at any moment a convulsion may reveal his carefully guarded secret to a gaping public.

Every patient and every family confronted with epilepsy has apprehensions born of general misunderstanding. The physician can counteract these sentiments by words such as these: "Epilepsy is not a mysterious disease and certainly is no disgrace. Simple epilepsy, like diabetes, is a metabolic disorder. It is, perhaps, an enigma, but not a stigma. It does not tend to get worse with time. There are effective medicaments. The mind is rarely affected. A child should continue schooling, and the adult should work. Activity is an antagonist of seizures. Marriage and children are not necessarily precluded. Given social acceptance, the great majority of patients can lead normal lives."

General conclusions such as these must be tailored to fit the individual person. The good physician must search for and dispose of specific questions that fester in the

From the Children's Medical Center.

Read before the Section on Nervous and Mental Diseases at the 102nd Annual Session of the American Medical Association, New York, June 3, 1953.

This article is No. 59 in a series, Studies in Epilepsy. The Rockefeller Foundation and the United States Department of Public Health, Social Security Agency, aided in this study.

mind of a patient and his relatives. Because most anxieties about epilepsy are unfounded, most persons should leave the physician's office more hopeful than when they entered. Maintenance of the person's good hope and morale is more important than adherence to details of doubtful importance such as the time of taking medicine, the diet, and avoidance of excitement.

Unnecessary prohibition of social events or of sports such as bicycling, horseback riding, or swimming may affect the relationship between the child and his parents or his physician. To understand the patient's anxieties and to do something about them takes a sympathetic understanding of the person and his emotional problems. This many physicians lack. For example, the writings of John Hughlings Jackson, epilepsy's great benefactor, display no spark of interest in the patient as a person.

Thus, for the patient adequate treatment hinges on finding an adequate physician. The patient wants to be sure that the physician knows or will inform himself about epilepsy, that his words can be trusted, and that his interest is genuine. An incorrect diagnosis can be forgiven, but distraught patients do not forget the impatience, callousness, and downright inhumanity displayed by a few physicians, some of them specialists in high places. Scientific interest is no substitute for doing good just for love of goodness. As by osmosis, the trusted physician conveys confidence and hope to the downhearted. In return, through intimate association with the cheerful endurance and courage of his patients, he may receive more than he gives.

The physician's treatment of emotional and social handicaps involves two fields. The first is personal contact with the patient and his family and friends. The disability due to epilepsy for different persons is from near 0 to near 100%. In the latter zone are those, usually children, who are beyond restoration of reason or of health. The physician who can communicate courage in such a disaster is extraordinary. "The physician is privileged," said Dr. Holmes, "to cure seldom, to relieve often, to comfort always." The second contribution is correction of the public misunderstanding of epilepsy and revision of laws that discriminate unfairly.

PUBLIC RESPONSIBILITY

The widespread discrimination against the epileptic is the heritage of many centuries during which there was no treatment and the epileptic inmate of the insane asylum or the town idiot was considered representative of all those who had convulsions. Because of the electroencephalograph and modern drug and surgical therapy public prejudices are fading. However, mistaken conceptions of early physicians and politicians have hardened into rigid laws and have been inherited. "Demon possession" is dated, but some laws contain a chain-gang-like procession of words no less sinister: the criminal, the insane, the morally and mentally defective, the epileptic. These, some statutes intone, shall not be accorded certain general rights.

For example, present immigration laws forbid the entrance of an epileptic into the United States even on a visitor's visa, unless the seizures are due to brain damage. The judge of a supreme court bringing his daughter for medical advice was detained at Ellis Island and required to post bond that he would leave. A music teacher coming from Canada had phenobarbital in her suitcase; she was taken from the train, not permitted to communicate with those expecting her, and returned home under guard. A Canadian businessman on one of his numerous trips to the United States was asked at the border why a chauffeur was driving; that ended his visits. Certain rights tend to be curtailed either by law or by public practice. Three are outstanding: the right to learn, the right to marry and bear children, and the right to work.

EDUCATION

Mental and physical activity results in formation of the acids that tend to inhibit epileptic seizures. The epileptic person needs education also as an offset to his handicap, as a stimulant to morale, and for social development. The departments of education of certain states deny to him the facilities of rehabilitation, but the largest difficulty is the complaint of teachers and the parents of other children that the epileptic child is a hindrance to the healthy. Yet the child whose seizures are reasonably controlled can be a positive asset in the classroom. Deft handling of convulsions is a lesson in first aid. Association with a person who carries on in spite of such a handicap is a lesson in brave living. One must reconsider the effect of the sight of a convulsion on school children when the murder and mayhem that they view every night on television is remembered.

Another difficulty is the inherited conception of mental deterioration and an unpleasant personality. Too little has been written about the majority group, those treated as office patients. Under Dr. Alice Collins, 600 of our patients have been given routine intelligence tests. The average score was 109 (90 to 110 being the normal range). Those with evidence of brain disease scored about 7 points below the metabolic (essential) group. Not epilepsy but natural endowment or acquired brain disease determines mentality. The older the patient, the higher the intelligence quotient. Of the older group with normal mental states, 28% had a score of 120 or more; hence they are classed as mentally superior.[1] However, uncertainty of acceptance by schools increases with the ascent of the educational ladder.

Schools of higher education, to the number of 1,676, were asked regarding acceptance of educationally qualified epileptic students.[2] Only 21% did not reply; 21% said epileptics were admitted if certain conditions were met; 44% had not formulated a policy; and 14% did not accept them. Distribution of answers with respect to the type of education offered is shown in figure 1. Besides the type of education offered, the size of the student body, the section of the country, the presence or absence of a department of student health, and previous experience with epileptic students were items that influenced the degree of hospitality. Many schools criticized family physicians for lack of candor; many asked for guidance.

MARRIAGE

Discouragement and prohibition of marriage stems from the Dark Ages. The Swedish law dates from 1757.[3] Seventeen of the United States forbid marriage. The discrimination is not practiced because the degree of inherited or physical impairment is unusual, for obesity or diabetes is probably a greater threat to life than essential (metabolic) epilepsy, and migraine is more clearly hereditary. The ancient fear is of mental decay. But the cause of decay, when such is present, rests not on the metabolic disturbance of brain cells that causes simple epilepsy nor (except rarely) on the seizures themselves but on some structural damage to the brain. Such damage is usually acquired subsequent to conception and hence is without genetic influence. The federal law that forbids entrance of the epileptic without brain damage but admits the one whose seizures are due to such damage (and is the likelier to become a public charge) is, of course, ridiculous.

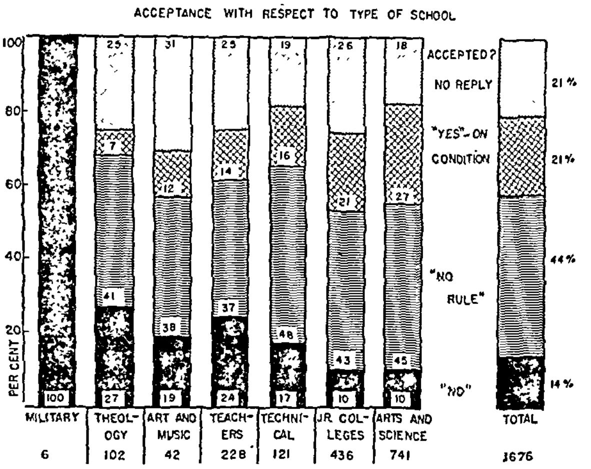

Fig. 1.—Distribution of replies from questionnaires sent to 1,676 colleges and universities with reference to the type of instruction given. The number of schools appears at the bottom; numbers within columns are percentages.

At this section meeting three years ago one of us presented electroencephalograms and other data on 122 twins subject to seizures.[4] The series now numbers 155 pairs. That a genetic factor (probably recessive in type) is important cannot be questioned, but five other considerations must also be weighed: 1. The degree of heredity for epileptics varies widely. The average epileptic, if such existed, could expect that the chance for seizures in any given child would be about 1 in 30, but there would be a 50-50 chance that these would be limited to a few in childhood. Hence, likelihood of recurrent attacks would be perhaps only 1 in 60, or three times the chances of the average nonepileptic. A few of these cases, the most serious, would be the direct result of some acquired brain disease. 2. Epilepsy per se is not inherited, and only the tendency is. Hence carriers of the tendency, many times more numerous, are genetically much more important than the affected. Unless carriers are controlled, even sterilization of all epileptics would not appreciably reduce the incidence for many generations. 3. Possession by parents of transmissible mental and physical traits that are desirable may outweigh an undesired tendency to seizures on the part of one parent. 4. A transmitted predisposition, what Galen called "an aptitude of the body," is no more important for epilepsy than for many other diseases. Progeny denied for one should be denied for all. 5. Methods of prevention and control of acquired epilepsy are at hand. Prevention of brain disease and also successful drug treatment have advanced importantly in recent years, and additional gains are probable.

Certainly persons with strong evidence of heredity of seizures and of poor mental or physical traits should not procreate. They might marry and practice continence or, if not Catholic, birth control. Clearly the case of each couple proposing marriage must be judged individually. Only rarely do we find it necessary to give adverse advice to those who consult us. Because physicians were responsible for the unfair laws of the past century, they have a present duty to press for their annulment. Under leadership of Dr. Edward Schwade, Wisconsin's marriage law has recently been rescinded. Although these laws are rarely enforced, the emotional trauma of the stigma persists.

The laws and public opinion on marriage and birth rates have had some effect. In Sweden the law against marriage, nearly 200 years old, has not reduced the marriage rate except for those who contracted the disease early or who were mentally affected; however, the live births per patient numbered only one-half of the 3.3 children per family for all Sweden.[3] We have tabulated data concerning 943 office patients 18 years of age or older. The proportion who are married (figure 2) for the total group is 45.5%. Among 143 clinic patients in Montreal,[5] the proportion was 37.1%. The U. S. census for 1940 reported 68.9%. The men of our group were married in the proportion of 43.4% and women 48.1%; corresponding percentages for the U. S. population in 1940 were 65.2% and 72.7%, respectively.

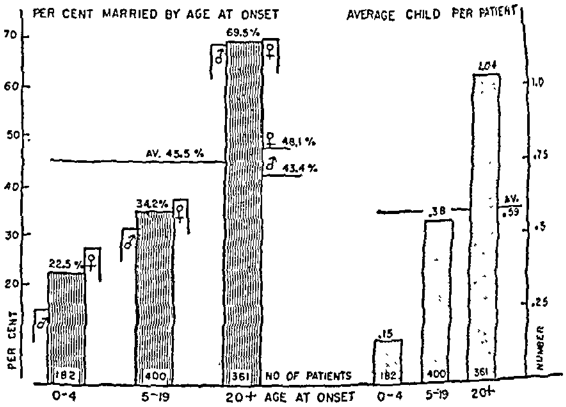

Fig. 2.—Of 943 epileptic patients, the percentage who married and the average number of children (of the 943 patients) with reference to the age of patients at the onset of epilepsy are tabulated. In this and figure 3 *numbers at base of columns refer to patients.*

The marriage rate of patients is depressed by those whose epilepsy began early in life. (Febrile or isolated seizures of childhood were disregarded.) If the onset was in the first decade, the marriage rate (22.5%) was only a third of the rate (69.5%) if the illness began at

[5] Thomas, J. C., and Davidson, E. McL.: Social Problems of the Epileptic Patient, Montreal Neurological Institute, Montreal, 1949, p. 64.

20 years or later. This difference is greater for men than for women. Chances of marriage for persons whose seizures began after the age of 19 were the same for men (69.3%) and women (69.7%), but if seizures began in the second decade the rates were for men 30.9% and for women 37.7%. If they began in the first decade, the rate of the men (14.8%) was only half that of the women (29%). For the whole group, the birth rate (0.59 child per patient) is proportionately far less than the marriage rate (45%).

That a long history of seizures should prejudice the chances of marriage is to be expected, although mentality and the frequency and character of attacks should also play a part. The relative disadvantage of the man may be due to his role as wage earner. The housewife would not lose her job because of seizures. Neither this series nor that of Alström[3] took into account the age of patients and whether in those with late onset the epilepsy antedated marriage. In the Montreal study seizures of 53% of the 53 married patients were present before marriage. The average age of our patients was about 32, which means that the full expectancy of marriage and children had not been realized.

Figure 2 also gives the average number of children of the 943 patients, again divided on the basis of the person's age at the initial attack. For the whole group there was a trifle more than half a child (0.59) apiece. The numbers reflect the additive effect of both marriage and birth rates. Thus, of the 182 who became epileptic in the first decade there was but 0.15 child for each; for those epileptic after 19 years 1.04 child for each, a sevenfold increase. There was only a threefold increase in marriages between these two groups; hence a long history of seizures reacted especially on births.

Of more particular interest are birth rates for the 493 patients who achieved marriage. The results are displayed in figure 3. The proportion with one or more children was 41% when seizures began in the first decade, 62% for the second decade, and 67% when attacks began after the age of 19. Here again the proportion of women was higher than for men; namely, 64% against 60%. Certainly the wife's epilepsy did not interfere with her child bearing; however, even the top rate of 67% is below the expected. In replies received from 939 married nonepileptics 86% had one or more children. Among 3,022 American college teachers, 80%[6] had children.

Figure 3 shows the number of children per married couple. The average total was 1.28. If the patient-parent had seizures in the first decade the number was 0.66, in the second decade 1.1, and after the age of 20, 1.5. In this tabulation the number of children was the same for men and women. Even in the favored group in which seizures began after the age of 19, the number of children, 1.5, is well below the number of children in the average American family. In a study of the group of 939 persons already mentioned the average number of children was 2.3.

Of the 554 children, 12, or 2.2%, had experienced one or more seizures. This proportion (one in 45) does not seem large enough to dissuade parents from having more children, but the general hue and cry about heredity is often a deterrent to the more conscientious. The data suggest that natural selection rather than legal restraints determines the marriage of epileptics and that those who marry tend to exercise birth control. It is still questionable whether this is true for patients who are Catholic, and if not whether lack of control would help to explain the reputed high incidence of epilepsy among Catholics.[7] Obviously, the whole subject of marriage deserves continued study.

EMPLOYMENT

Perhaps the most difficult social problem for those who treat the adult epileptic is employment. Of what use is it to rid the person of fits, says the physician, if he remains an economic invalid because he is denied the right to work. Enforced illness is a menace to pride and morale, but it also drains the public purse. To sustain in idleness masses of men and women because of a dislike of seizures is wasteful folly. As a rule, employment is refused the known epileptic. Hence, many conceal their history and may be given work (such as the operation of moving vehicles) that is hazardous for themselves and the public.

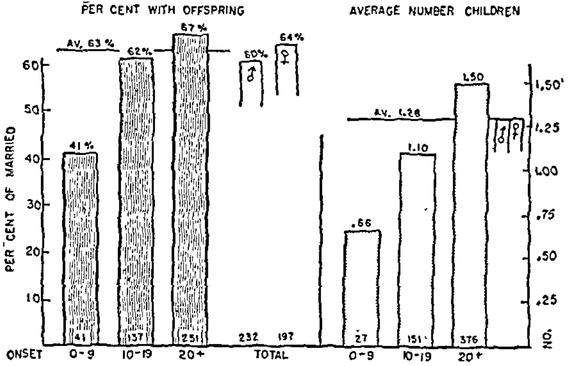

Fig. 3.—Of 429 patients who married, the proportion with offspring and the average number of children per marriage, with reference to the age of patients when seizures began, are tabulated.

In four states epilepsy, like syphilis and smallpox, is reportable to health authorities. The effort to prevent highway accidents is laudable, but in catching the rare offender lawmakers conveniently forget the everyday one, the alcoholic. Besides violating professional confidence, the law tends to keep the patient from seeking the treatment he needs or it encourages the physician to hedge his diagnosis. Permission to drive should be considered individually, depending on the advice of a physician qualified in epilepsy. Some physicians act obstructively. Thus, a company physician specified that a worker who, with medication had been seizure-free for five years, must have a companion with him always, a condition that could not be fulfilled. Civil Service requires a sedentary job, something both undesirable and unnecessary.

Refusal to employ is based in part on the emotional reaction of fellow workers or of customers to the sight of a seizure. More important, however, is the supposition that the epileptic will have a high accident rate, which might increase the employer's insurance rates under the provisions of the Workmen's Compensation Law. As a matter of fact, an unusual accident rate has not been demonstrated. Any observed rate would be artifically high because it would be based on only a portion of the epileptic enrollment. Those who have not had attacks and injury while at work are not known to the management. More general enactment of "second injury" provisions would solve the difficulty. The American Federation of the Physically Handicapped proposes an assessment of 0.1% of wages. This would provide a special fund from which compensation would be paid for injuries the result not of the employment but of the person's disability.

[7] Roberts, B. H., and Myers, J. K.: Religious Sects and Mental Health, read at the American Psychiatric Association, May 8, 1953.

Data collected between 1931 and 1941 from a group of 1,105 clinic patients 18 years of age or over found 73% employed.[8] The employers presumably in most cases were unaware of the epilepsy. Among 639 men, professional men, business men, and college students formed 27%; clerical and skilled workers 28%; sales clerks and servants 20%; and unskilled laborers 25%. The danger of secrecy is emphasized by a 4% representation of taxi, bus, and truck drivers.

Certainly, except for the increasing emphasis on accident compensation, the social conditions of the epileptic are improving. A Gallup poll of public opinion in 1949 [9] disclosed that 57% of persons knew an epileptic; 56% had witnessed a seizure; 57% would not object to having an epileptic in school with their children; 59% did not think epilepsy a form of insanity; and 45% thought they should be employed in jobs like other persons. The relative low position of employment may reflect failure of the question to eliminate jobs clearly dangerous. Persons with a college education gave the most favorable answer to all these questions.

To acquire additional and more recent evidence from the private patient class of patients, we sent questionnaires to 375 office patients seen in the past two years. Replies were received from 173 (46.1%). Ages were from 20 to 65, the average being 32 years. Seventy-five per cent had gone beyond grade school, 54% through high school, and 21% through college. Excluding housewives and students not specifically employed, 80% of the remaining 140 persons were employed. Of the 112 with jobs, 19 were in protected positions, employed by relatives or themselves. Of the 28 without a job, epilepsy was the reason in 15 (54%). Thus, of the whole 140, only 11% were unemployed because of their seizures. As for the difficulties of securing employment, 70% of 149 replying said that epilepsy had not prevented getting a job; however, whether prospective employers had been informed of the illness was not specified. Of 91 men who were not in protected employment, the illness was known to the employer in 55%. In the known cases the patient felt in almost every instance that he was getting fair treatment. The unions knew about the seizures in less than 4% of cases. Of 140 persons, 89 (63%) had experienced seizures while at work. Fifty, or 35%, had been discharged because of the illness. A seizure on the job was responsible in 40 cases. The employer heard of the illness through others in 10. In reports from 156 persons 15, or 9.6%, experienced some injury while at work. Of these 15, 2 were fired and 2 signed papers for release from compensation. Replies of patients emphasize the crucial role of adequate medical treatment. Above all they appealed for efforts to further a better understanding on the part of the public.

A more searching analysis of the work history of a larger group is needed. We members of the Physicians League Against Epilepsy have been remiss in not collecting a body of data showing the employment and accident record of patients with demonstration of what a good record this can be, given proper medical treatment and job placement

PHYSICIAN EPILEPTICS

As competition increases, employment becomes more difficult. Maximum competition is encountered at the doors of medical schools. Important advancements in certain diseases have been made by men who themselves have that disease. Yet, the applicant for training in medicine who admits epilepsy is at a severe disadvantage.

Experience with 43 epileptic physicians, a small subgroup of the employed not included in the preceding study, is appropriate for this occasion. Usually the self-employed are in a preferred position; however, the public that hires the services of a physician may be even less tolerant than the factory foreman. This accounts for the hesitancy of medical schools to admit epileptics. Seizures began before medical school in 8 of the 43 and during school years in 3. Of the eight, five (two pediatricians, an internist, and two neurologists) have specialized in epilepsy. Specialties represented are: internal medicine 10, surgery 9, pediatrics and psychiatry each 4, general practice 3, roentgenology, anesthesiology, laboratory technology, gynecology, and neurology, 2 each, and tuberculosis, research, and ophthalmology 1 each. Two physicians hold full professorships in medical schools.

Twenty-four had grand mal alone, 12 grand mal and psychomotor disturbances, 1 grand mal and petit mal, and 6 psychomotor disturbances alone. Nine died: two from brain tumor and one each from diabetes, lung cancer (he was a chain smoker), cerebral hemorrhage, fall in a seizure, burning, drowning, and unknown causes.

The social and emotional complications of this group seem to have been greater than for an average group, and follow-up has been unusually difficult. Three of the physicians had only one seizure. In 10 others seizures, at last report, had been absent for three years or longer. The others have carried on in spite of epilepsy. Perhaps of greatest interest is the fact that, so far as is known, only one has had to abandon the practice of medicine because of his seizures. As already stated, five have made the study and treatment of epilepsy their life interest. Epilepsy is most in need of dedicated physicians. What better source than physicians who are themselves affected?

SUMMARY

Epileptics and those who treat them are today thrice blessed. First, they have the electroencephalograph, a device that displays essential disease activity of the brain. Second, they have the benefit of new medicines and of fresh surgical techniques. Third, they have the stimulus, the exhilaration of a fight yet to be fully won, a battle against ignorance, prejudice, and fear.

USE AND ABUSE OF CORTISONE AND CORTICOTROPIN (ACTH) IN DERMATOLOGY

Paul A. O'Leary, M.D.
and
John G. Erickson, M.D., Rochester, Minn.

Four and a half years have elapsed since we first treated patients who had lupus erythematosus and psoriasis with cortisone, and in four previous reports [1] our colleagues and one of us (P. A. O'L.) have recorded our experiences with and impressions of the value of cortisone and corticotropin (ACTH) in the treatment of various dermatological conditions. From the beginning, it was apparent that cortisone did not cure patients with skin diseases, although in some cases the symptoms were minimized and in other cases of fatal diseases the life expectancy may have been extended. At the present time, cortisone and corticotropin are used extensively and sometimes indiscriminately in the treatment of cutaneous diseases of all types, and patients with dermatoses that run a short and self-limited course and those with fatal skin diseases now receive these drugs uniformly. It is not a new experience for physicians to use a drug that does not cure but that may give temporary symptomatic relief and while doing so lead to the production of serious sequelae. Both cortisone and corticotropin have these qualities. The administration of excessive doses of these drugs or their prolonged use may produce serious and prolonged undesirable reactions, which sometimes disappear when treatment is discontinued. The experience thus far accumulated suggests that these unfavorable sequelae may become manifest months after the administration of the drug is stopped and that they may be of a serious nature. It is evident that patients differ in their tolerance of these hormones.

The physiological effects of the steroids have been recorded repeatedly, but they are significant enough to warrant restating.[2] Although the details of the mechanism of their action are not completely understood, it is now accepted that the administration of cortisone or corticotropin suppresses the secretion of endogenous adrenocorticotrophic hormone by the anterior lobe of the pituitary body. In addition to the unfavorable side-effects as noted in the skin, namely increased pigmentation, hirsutism or alopecia, seborrhea-like dermatitis, acne, atrophic striae, and the "moon face" of Cushing's syndrome, it is necessary to bear in mind that cerebral disturbances such as euphoria, depressed states, frank psychoses, convulsive attacks, and changes in personality may develop. In addition, alterations in the electrolyte metabolism resulting in retention of salt and water associated with edema and gain in weight may require adjustment of the intake of sodium chloride and potassium. The transient hyperglycemia usually disappears when administration of the drug is stopped, although the hypertension that develops may persist and be serious. Intercurrent infections, such as tuberculosis, peritonitis, streptococcic and staphylococcic infections, and influenza, may be masked by the administration of these drugs and accordingly overlooked.

Gastric and duodenal ulcers may bleed or perforate; suppression of gonadal activity with irregular menses and decrease in libido may be noted, and local urticarial reactions and anaphylactic shock may follow intramuscular injection of corticotropin. Teicher and Nelson [3] called attention to the appearance of osteoporosis in cases in which cortisone had been administered for a long time. This may be related to a prolonged negative nitrogen balance. The question of hypercoagulability of the blood as the result of steroid therapy is not definitely established, as there are advocates for and against the idea. Thromboembolic phenomena and thrombophlebitis may occur, but the cause or mechanism of their production is unknown.

According to Sulzberger and Baer,[4] the actions of corticotropin and cortisone on cutaneous physiological, pathological, and immunologic processes have been studied by Herrmann, Sauer, Millberg, and their associates at the New York University Post-Graduate Medical School and by other investigators elsewhere. The following actions were mentioned: "The skin temperature tends to become elevated. . . . The delivery of sweat to the surface tends to be increased. . . . The delivery of sebum to the skin surface tends to be diminished. . . . The flow in the peripheral blood capillaries tends to be accelerated. . . . The nonallergic and allergic immediate urticarial response to scratch or intradermal tests appears to remain grossly unaltered or to be but slightly diminished. . . . According to some reports, in many cases the 48 hour tuberculin type response undergoes a more or less marked reduction or even becomes abolished. . . . There appears to be an inhibitory effect on the activity of hyaluronidase. . . ."

Ill-defined clinical signs of varying degrees of severity that suggest depressed adrenal cortical function may occur in the form of weakness, fatigability, and a drop in the blood pressure.[5] These may be noted after the

administration of cortisone or corticotropin is stopped. Nausea and depression also may be present. All taken together indicate that the administration of the drug has been discontinued too rapidly. These symptoms may persist for varying periods of time and are not dependent on the dose of the drug or on the duration of the treatment. In addition, the excretion of 17-ketosteroids is sometimes decreased shortly after administration of cortisone is started, and this decreased excretion may persist during administration of the drug and for a variable period thereafter. In fact, this decrease is used as a test for adrenal function by some investigators. Neither the shortest period of treatment nor the minimal dose of cortisone that will produce suppression of adrenal cortical function is known, although it is suggested that any dose that equals or exceeds the daily requirement may suppress the endogenous function of the adrenal cortex, and this dose may be as small as 20 mg. a day.

Salassa, Keating, Bennett, and Sprague [5] said that cortisone has been known to produce atrophy of the adrenal cortex and thus impair adrenal cortical function. These effects may last for a considerable time after the administration of cortisone is discontinued. They are believed to be the result of impaired production of endogenous adrenocorticotrophic hormone by the anterior lobe of the pituitary body. Adrenal atrophy may lead to acute insufficiency of the adrenal cortex in cases in which the patients undergo any stress such as that associated with a surgical procedure. These authors said that the administration of corticotropin may produce the same effects as the administration of cortisone.

The administration of cortisone in cases of dermatological disease may produce other clinical effects, which cannot be explained at this time. In some cases, the morphological features of the disease change and are replaced by another clinical syndrome. This effect is exemplified in cases of the mild systemic type of lupus erythematosus in which the features of lupus erythematosus may disappear and be replaced by the classic clinical and pathological signs of psoriasis. Patients who have incompletely generalized dermatitis may be benefited by the first course of cortisone therapy, but they may not receive any benefit from the second course after the disease has recurred. In some cases of classic dermatosis, the administration of cortisone or corticotropin distorts the morphological features of the lesions so much that they cannot be recognized. The generalized hyperpigmentation that may follow a course of cortisone therapy may confuse the clinical picture. Diseases such as psoriasis and lichen planus, which occasionally become generalized, may spread rapidly and become universal while the patient is undergoing treatment with one of the steroids.

Contraindications to the use of cortisone or corticotropin include heart failure, hypertension, renal insufficiency, psychotic tendencies, duodenal ulcer, and tuberculosis. Diabetes mellitus is not a contraindication to the administration of these drugs, since it is not difficult to control unless large doses of these drugs are used.

BENEFICIAL EFFECTS OF CORTISONE AND CORTICOTROPIN

There are several indications for the use of cortisone and corticotropin, and certain benefits follow their administration in dermatological practice. It is now generally agreed that neither of these drugs is curative and that the favorable results of treatment of different types of dermatoses with these drugs are variable. In those diseases in which treatment is said to produce marked improvement, the good results do not appear regularly in each case. On the other hand, in cases in which benefit from treatment is not anticipated the patients occasionally will display evidence of remarkable improvement. This therapeutic inconsistency tends to make treatment with these drugs a trial procedure in each case. Corticotropin and cortisone have been of value in two diseases that cause death, namely, pemphigus vulgaris and systemic lupus erythematosus. They apparently are more effective on the vulgaris type of pemphigus than they are in the foliaceous and vegetative types.

If a remission occurs, it lasts longer in cases in which the disease is of the foliaceous type than it does in cases in which the disease is of the vulgaris type. In most cases of pemphigus, the oral administration of 200 mg. or more of cortisone per day will stop the formation of blebs and blisters. In an occasional case, the oral administration of 400 to 500 mg. of cortisone per day or the intramuscular injection of 100 to 150 mg. of corticotropin may be necessary to control the pemphigus. We have not found it necessary to administer larger doses. Oral administration of 50 to 100 mg. of cortisone per day usually is necessary to maintain a remission, and we have found that potassium chloride and ascorbic acid are valuable adjuncts. When the administration of cortisone is discontinued or its dose is reduced too rapidly, the cutaneous lesions usually recur, and the recurrent lesions are severer and more resistant to treatment than were the original lesions.

In a few cases of pemphigus vulgaris in which cortisone has been administered for three years, there has not been any recurrence of the disease.[6] In other cases of pemphigus the disease has not recurred although the administration of cortisone has been discontinued. Many patients have not derived any benefit from the administration of cortisone or corticotropin and have died of the disease.

In cases of lupus erythematosus of the acute and severe systemic type, administration of cortisone frequently will produce a remission, which may be maintained for several years. Although the severity of the clinical symptoms is lessened, laboratory examinations reveal little change since hematological examination still discloses lupus erythematosus cells, an increased sedimentation rate of the erythrocytes, and leukopenia, and urinalysis reveals evidence of renal disease. The clinical improvement is characterized by an increase in sense of well-being, by a decrease of fever, and by a lessening of the severity of the arthralgia and facial erythema. A decrease in the extent of the pleural and peritoneal effusion occasionally will occur. In the acute type of this disease, a recurrence is uncontrollable if it develops while the patient is receiving cortisone. In the subacute types of lupus erythematosus, in which the clinical symptoms are less severe than they are in the acute type and the laboratory findings are less significant, the symptomatic results are less striking. In our experience, with a rare striking exception, the remissions that occurred in most of our patients with acute systemic lupus erythematosus have been of short duration and the patients eventually have died of the disease. Neither time nor space warrants our enumerating detailed experiences in the treatment of other cutaneous diseases with cortisone or corticotropin, but there have been decidedly more therapeutic disappointments than successes.

[5] Salassa, R. M.; Keating, F. R.; Bennett, W. A., and Sprague, R. G.: Postoperative Adrenal Cortical Insufficiency: Occurrence in Patients Previously Treated with Cortisone, J. A. M. A. 152: 1509-1515 (Aug. 15) 1953.

[6] Lever, W. F.: Personal communication to the authors.

In cases of sarcoidosis, lymphoblastoma, dermatomyositis, scleroderma, and acrosclerosis, the results of treatment with cortisone or corticotropin are unsatisfactory. In fact, we now believe, contrary to our early opinion, that acrosclerosis is a definite contraindication to the use of corticotropin or cortisone. We know of six cases in which the patients, who were young women with acrosclerosis of two years' duration or less, died of cerebrovascular accident associated with severe hypertension and renal disease. These are not common complications of acrosclerosis but are significant in view of the fact that they appeared three to four months after the administration of cortisone was started. Since necropsy was not performed in any of these cases, evidence that cortisone was responsible for the development of these complications is presumptive. We feel, however, that these cases are worth recording. Neither corticotropin nor cortisone will produce permanent improvement in cases of cutaneous sclerosis of the localized, generalized, or acrosclerotic type.

The influence of cortisone and corticotropin on the less severe skin diseases, those characterized by inflammatory cutaneous reactions, is often striking and really worth while; however, the improvement is variable and not predictable. In dermatitis venenata (poison ivy), Wrong and Smith[7] reported that the administration of cortisone produced excellent results in 8 of 15 cases of contact dermatitis due to Rhus toxicodendron (poison ivy). In these cases, it shortened the course of the disease, caused softening and drying of the blisters, and reduced the severity of the erythema and edema. Equally favorable results have been obtained in cases of acute drug eruptions, urticaria, angioneurotic edema, and erythema multiforme. In the treatment of these diseases, cortisone or corticotropin should be administered for two or three days. Cortisone should be administered orally in daily doses of 200 mg. or less, or corticotropin should be administered slowly by the intravenous route in doses of 25 to 50 mg. per day.

Some physicians believe that atopic dermatitis is helped materially by cortisone therapy. Our experience would indicate that the only significant benefit in cases of this disease is the relief of paroxysms of itching, and this is not great enough to warrant the use of cortisone. Occasionally, a remission will occur and may be maintained by constant treatment. As is true in cases of other diseases that have been mentioned, if the dermatitis recurs after the administration of cortisone, it is severe and resistant to all types of treatment.

Dillaha and Rothman[8] reported that a rapid regrowth of hair occurred after the oral administration of 100 to 150 mg. of cortisone acetate per day in cases of alopecia areata and alopecia totalis. We also noted a definite return of hair in cases in which cortisone therapy was administered, but the growth was irregular and the hair fell out when the administration of cortisone was stopped. In some cases, it even fell out while the drug was being administered. Cortisone will cause hair to regrow, but the patient is usually unable to keep it.

In an occasional case of eczema, psoriasis, seborrheic dermatitis, or similar type of dermatosis, the patients will derive great benefit from the oral administration of 100 mg. of cortisone a day for three or four days. The second or third course of treatment may not produce a similar response, and not all of the patients will be benefited by the initial course.

Although the topical application of cortisone or corticotropin generally has not proved satisfactory in the treatment of dermatological diseases, Sulzberger, Witten, and Smith[9] recently reported that an ointment containing 1, 2.5, or 5% of hydrocortisone acetate was of considerable value as an antipruritic in cases of atopic dermatitis, eczema, pruritus ani, pruritus vulvae, and localized neurodermatitis, The ultimate effects of the local application of this drug are not known. Whether or not it will cause undesirable side-effects can be determined only by further trial and study. At present, this drug is prohibitively expensive.

INVESTIGATIVE DATA

Although extensive investigations have been undertaken in the field of immunologic reactions and hypersensitivity, there is still some controversy as to the exact site of the blocking of allergic responses by cortisone or corticotropin. Perhaps the blocking occurs in the tissues rather than as an antigen-antibody neutralizing reaction in the blood. The data accumulated by various investigators suggest that (1) cortisone and corticotropin do not alter the result of skin tests with specific antigens, either urticarial or eczematous[10]; (2) these drugs do not act as antihistaminic agents or affect the passive transfer reaction[10]; and (3) they do not influence the result of the tuberculin, Dick, or Schick tests.[11] The result of most experimental work suggests that they do not protect a patient from anaphylactic shock or interfere with the delayed type of hypersensitivity reaction such as the Jarisch-Herxheimer reaction.[12] It recently has been postulated that an antihyaluronidase activity of the cortisone or corticotropin may be responsible in part for the amelioration of the collagen diseases[13]; however, none of the mechanisms suggested thus far seems to explain satisfactorily the action of the steroids in the collagen diseases.

EFFECTS ON INFECTIONS AND LYMPHOID TISSUE

Cortisone and corticotropin have a suppressive effect on inflammatory reactions and have a tendency to mask the signs of intercurrent infection. As a result, abscesses may form; tuberculous lesions may become more extensive; peritonitis, septicemia, and other serious complications may develop, and systemic fungous infections may be disseminated. These complications may not be recognized until they are far advanced. If the administration of cortisone or corticotropin is discontinued abruptly when one of these complications occurs, adrenal cortical insufficiency may develop. Cortisone and corticotropin cause destruction of some types of neoplastic tissue and normal lymphoid tissue.

CONCLUSIONS

Our therapeutic experience over the past four and a half years and our growing appreciation of the severer complications that may ensue during or after the administration of cortisone and corticotropin have led us to reduce our absolute and relative indications for the use of these hormones to the following conditions: (1) self-limited hypersensitivity reactions of severe degree unresponsive to more conservative measures, such as acute urticaria, certain acute drug eruptions, acute angioneurotic edema, acute dermatitis venenata, and erythema multiforme, and (2) serious or otherwise fatal conditions, such as pemphigus and systemic lupus erythematosus.

Although temporary benefit may be obtained from the use of these drugs in some cases of neurodermatitis and in an occasional case of dermatomyositis, psoriasis. dermatitis herpetiformis, and seborrheic dermatitis, the short duration of the improvement, the frequency of severe relapses that often are severer than the original condition, and the character of the complications that the drugs may produce contraindicate their use except under exceptional circumstances. Dermatological conditions in which there is no place for the use of cortisone and corticotropin are too numerous to list here. This group includes the great majority of skin diseases.

The effects of cortisone and corticotropin are seen in almost every system of the body. Therapeutically, their usefulness in dermatological practice is limited primarily to decreasing the reaction of tissue to injury and to decreasing allergic and hypersensitivity reactions. Although the healing of self-limited lesions may be accelerated, although chronic conditions may be temporarily ameliorated, and although life may be prolonged in cases of serious fatal diseases, the physician must weigh the potential dangers and probable undesirable side-effects, including death, of cortisone and corticotropin against the advantages in each case. Once therapy is instituted, it is necessary to maintain adequate but not excessive dosage, to discontinue administration of the drug gradually and slowly, and to anticipate the onset of complications during and after treatment.

As in the appraisal of all new therapeutic agents, the display of enthusiasm begins to wane as experience points out the inadequacies of the agents and complications produced by them. The praise for cortisone and corticotropin in the treatment of skin diseases has waned considerably in the past year, and their overenthusiastic use has stimulated us to join other authors in cautioning against their unnecessary use.

COMMON WHIPLASH INJURIES OF THE NECK

James R. Gay, M.D., White Plains, N. Y.
and
Kenneth H. Abbott, M.D., Columbus, Ohio

Interest in whiplash injury of the neck was aroused by the frequency in which this type of injury was encountered in neurosurgical practice and by the chronic nature of the symptoms that were observed after an accident that appeared to be of little consequence. In our experience, most of the accidents that involved a whiplash injury of the neck were caused by a collision in which one vehicle was rammed from behind by another vehicle. Since it has been estimated [1] that about 15% of all automobile accidents resulting in death, injury, or property damage are caused by a rear-end collision, it occurred to us that whiplash injuries might be encountered frequently in general medical practice. However, very little information on this subject has been published in textbooks or in the current medical literature.

PERSONS STUDIED

Fifty persons who suffered a whiplash injury of the neck between the years 1948 and 1952 were studied. Persons who received a direct blow on the head or neck were excluded. In this study, there were 35 women (70%) and 15 men (30%). Of those injured, 70% (35) were between 30 and 50 years of age (table 1). Housewives (17 cases, or 34%) made up the largest occupational group; other occupational groups represented in this series included 7 (14%) skilled laborers, 7 (14%) persons in clerical positions, 6 (12%) persons in managerial positions, 5 (10%) semiskilled laborers, 4 (8%) persons in sales positions, 3 (6%) professional persons, and one (2%) student. Farmers and unskilled laborers were conspicuously absent in this series, although the group of 50 patients lived in or near an industrial city that is surrounded by a large agricultural region.

Read before the Section on Nervous and Mental Diseases at the 102nd Annual Session of the American Medical Association, New York, June 2, 1953.

[1] National Safety Council: Personal communication to the authors.

Each patient had symptoms and findings characteristic of a sprain of the neck. In case of a simple sprain, the symptoms consisted of pain in the lower cervical spine, limitation of motion of the neck, and spasm and tenderness of the cervical spinal musculature. Movement or jarring of the neck made the symptoms worse, and, in an acute case, it was characteristic for the patient to support the head and neck with his hands. When the injury was remote, some experienced a sensation of difficulty in supporting their head. In rare instances in which a second whiplash injury occurred, all symptoms were immediately intensified. Tenderness and spasm were often present in adjacent musculature, including the muscles of the upper thoracic spine and shoulder girdle. No abnormal reflex or sensory changes were found in the extremities. Even without the complication of a cerebral concussion or more painful condition of the neck, the patient with a sprain showed marked hypertonicity of the neuromuscular system and general nervous symptoms.

Table 1.—*Age Distribution of Persons with Whiplash Injuries by Decades*

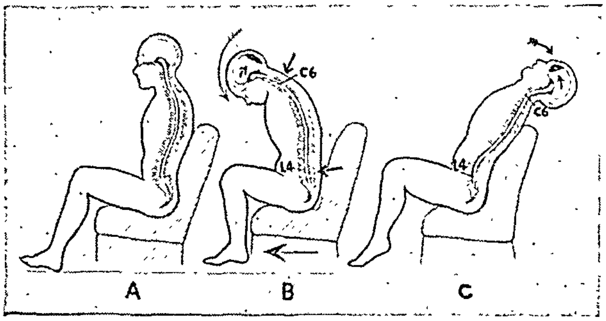
Age, Yr.	No. of Cases	%
10-19	1	2
20-29	6	12
30-39	15	30
40-49	20	40
50-59	6	12
60-69	2	4
	50	100%

The mechanics of the injury were interpreted as a sudden and forceful flexion of the neck, followed, in some instances, by several other less violent oscillations of the neck in alternating flexion and extension (see figure). The basic pathological change was mechanical trauma of the supporting ligaments of the cervical spine. The severity of the sprain was variable from case to case, but the seriousness of the injury was dependent on the number and variety of complicating conditions.

COMPLICATIONS

The commonest complication encountered was cervical radiculitis (35 cases, or 70%). These persons had intense pain in the posterior cervical region, with radiation of pain into the occipital region of the skull, lower jaw, shoulder girdle, upper anterior chest, or upper extremities. The pain was intermittent, had a sharp quality, and oftenest followed a pattern that suggested irritation of the fifth, sixth, or seventh cervical nerve root on one side. Severe cervical radiculitis was usually accompanied by marked spasms of the cervical muscles. There were occasional transitory abnormalities of reflexes and sensation in one or both upper extremities.

In 31 patients (62%), there was historical and symptomatic evidence of a cerebral concussion. These patients suffered a momentary lapse of consciousness (from seconds to one-half hour). They described a blinding or explosive sensation in the head at the time of the crash. Some recovered consciousness after the car was driven ahead several hundred feet by the impact, and sometimes the car was still in motion when they recovered consciousness. Immediately after the accident, they had a sensation of being bewildered, stunned, dazed, or dull. Headache usually developed within a few minutes or hours and was severest in the frontal region. Nervous symptoms were especially intense in this group of patients. Marked neuromuscular tension, restlessness, irritability, subjective vertigo, poor concentration, insomnia (sometimes caused by disturbing dreams of the accident), vasomotor instability, recurrent headaches, mood changes, and general nervousness developed in all of them. These symptoms were intermittent and recurrent but tended to improve within a few days or weeks. However, when there were severe symptoms from the neck injury, a profound emotional reaction due to the circumstances of the accident, or a predisposition for a psychoneurotic reaction to develop, it was usual for the nervous symptoms to return, recur, and persist for many months. By careful evaluation of the history, it was often possible to separate the symptoms of the concussion syndrome from the symptoms of psychoneurosis on a temporal basis. The mechanics of the concussion were interpreted as sudden mechanical deformity and pressure on the frontal and temporal lobes of the brain, which occurred when the forward movement of the brain was arrested against the anterior walls of the skull when the head and neck were whipped backward immediately after the initial acute flexion of the neck. It was possible that secondary and lesser concussions occurred to the frontal, temporal, and occipital lobes of the brain in some instances when multiple oscillations of the head and neck occurred in alternating flexion and extension (see figure). Another phenomenon in the production of a concussion in these cases, which may be more important than the mechanical factors already described, is acceleration or deceleration influence on brain tissue, which has been described in the experiments of Denny-Brown and Russell.[2]



Mechanics of whiplash injury; *A*, normal sitting position in automobile; *B*, collision from behind thrusts body in position of acute flexion, with maximum stresses at lower cervical and lumbar spinal regions; *C*, position of extension usually follows acute flexion posture. There may be more than one oscillation of head and neck in alternate flexion and extension. Shading of brain indicates that a concurrent concussion of the brain occurs from mechanical deformation or the influence of acceleration or deceleration.

A protruded intervertebral disk in the cervical region was diagnosed clinically in 13 cases (26%). These patients had persistent cervical radiculitis, with pain and paresthesias extending into one upper extremity or alternating in both extremities. When the pain and paresthesias radiated into the hand, the thumb and forefinger or the ring and little fingers were oftenest involved. Muscular spasm and limitation of motion of the neck were more marked in the instances of a protruded intervertebral disk than in those of cervical radiculitis alone. It was common to find tenderness over the spines of the lower cervical vertebrae. There were persistent changes in reflexes and/or sensation in the painful extremity. The brachioradialis and biceps reflexes were often either hyperactive or hypoactive when compared with those of the unaffected side. When there was loss of sensation to touch and pinprick, it was most easily demonstrated over the dorsum of the thumb and forefinger. All patients suffering from a protruded intervertebral disk were treated by conservative measures, but eventually two patients required neurosurgical intervention for removal of a protruded cervical disk.

[2] Denny-Brown, D. E., and Russell, W. R.: Experimental Cerebral Concussion, Brain 64: 93-164 (Sept.) 1941.

Hypertrophic arthritis of the cervical spine was diagnosed by roentgenographic examination in five patients. In each instance, the arthritic changes were most marked in the lower cervical region. All of these patients showed a persistent cervical radiculitis, which involved the lower cervical nerve roots. From a clinical standpoint, the presence of arthritis was considered a complicating factor of the neck injury. Narrowing of the lower cervical foramens was demonstrated roentgenographically in only one instance.

One patient showed subluxation of the lower cervical spine when lateral roentgenograms were taken with the neck in a position of flexion and extension. In one patient, a fracture of a lamina was detected by roentgenograms taken in an oblique direction.

The complication that was most distressing for both patient and physician was a persistent psychoneurotic reaction. More than half of the patients in this series (26 cases, or 52%) were seriously handicapped in this way. In our opinion, the circumstances inherent in a whiplash injury make all persons prone to the development of a disturbing emotional reaction.

The accident involved a sudden, violent, and unexpected jolt that was a disturbing experience. Since the victim was seldom incapacitated immediately after the accident, there was opportunity for development of considerable hostility toward the offending motorist. A tedious investigation usually followed the accident at a time when the patient was bewildered, emotionally disturbed, and uncomfortable. If an examination was conducted in a hospital emergency room or a physician's office, very little injury was found and the patient was usually sent home equipped with a vague program of rest and recovery. It was usually several hours later or during the next day that frightening symptoms began, such as pain in the neck and head, radiating pain and paresthesias in the limbs, or aching in the lower back. Most of these sensations had never been experienced before. Lacking understanding of the variety, extent, and nature of their injuries and ill-prepared to alleviate their discomfort, these patients were prone to the development of apprehension, anxiety, and neuromuscular tension.

From the clinical standpoint, the basic physical discomfort from a whiplash injury occurred from physiological hypertonus of the cervical muscles (splinting). Whenever hypertonicity of the cervical muscles occurred in response to anxiety, the patient's symptoms were definitely aggravated. Since some persons seem to be peculiarly prone to react to stress by hypertonicity of voluntary muscles, it is likely that such persons would be predisposed to the development of profound discomfort after a whiplash injury.

The symptoms of a psychoneurotic reaction were similar to the nervous symptoms that occurred after a concussion. They occurred, however, with full intensity late in the convalescent period. The development of psychoneurosis was the most important factor in delaying recovery. In some patients, the aggravation of legal action was considered important, but, even after settlement, these patients were often partially disabled by recurrent nervous symptoms. The first few hours and days after the accident seemed to be the critical period in the management of the patient, if a severe psychoneurotic reaction was to be minimized or avoided. Whenever the patient was carefully examined soon after the accident, informed of the nature and extent of the injuries, told what to expect in the way of symptoms, placed on a definite treatment program, and seen regularly with friendly reassurance, the psychoneurotic reaction that developed was mild and nervous symptoms did not delay recovery. On the other hand, when patients treated themselves, were inadequately informed about their injury, or obtained little or no relief from their symptoms by symptomatic measures, they were usually seriously disabled by a psychoneurosis and their recovery from the injury was jeopardized.

Injury of the lower back was a complication in 15 patients (30%). The basic low back injury was sprain or mechanical trauma of the supporting ligaments of the lumbar spine that occurred from acute flexion of the lower back at the time of the accident (see figure). Lumbosacral radiculitis developed in six patients with an injury to the lower back, and clinical evidence of a protruded intervertebral disk at the fourth or fifth lumbar interspace on one side developed in only four persons. One patient suffering a combined whiplash injury of the neck and protruded intervertebral disk required neurosurgical intervention for removal of the protruded lumbar disk. Minor chest injuries complicated the whiplash injury in five patients; all five were behind the steering wheel when the accident occurred.

EXAMINATION

A detailed neurological examination was performed on each of the 50 patients. Attention was directed especially to the head, neck, and upper extremities. Muscular spasm was observed and confirmed by palpation. Movements of the head and neck were tested in all directions. Pressure was applied to the cervical spine as a whole by pressing down on the head in both normal and tilted positions in order to reproduce radicular symptoms. The cervical spine, neck and shoulder musculature, and brachial plexus were palpated for tenderness. The reflexes, muscular strength, and sensation were tested in the neck and upper extremities. Similar examinations of the lower back and extremities were carried out in the case of a complicating low back injury.

The roentgen examination of the cervical spine was an important adjunct procedure in defining the pathology of the injury. Even if the results of this examination were normal, as they were in 25 cases in this series, the clinical diagnosis of sprain was supported by excluding fractures, dislocations, and arthritic changes. In our experience, six views of the cervical spine were considered important —anteroposterior, lateral, right and left oblique, and lateral views in flexion and extension (table 2). The roentgen examination was most valuable as a clinical tool when technically excellent films were obtained, and they were reviewed personally with the radiologist.

In this series, five patients were examined by electroencephalography. Two patients had cerebral dysrhythmia that was interpreted as suggestive evidence of a brain injury.

TREATMENT

Therapy began with a thorough and unhurried history and physical examination that included roentgenograms of the cervical spine. Whenever there was any question of a direct head injury or a low back injury, a roentgenographic examination of the skull or lumbosacral spine was performed. Once the injury was defined, it was important to explain to the patient the nature and variety of injuries that had occurred. Persons who suffered a whiplash injury required unusual personal attention, explanation, and reassurance. Patients who understood their condition thoroughly and who had confidence in their physician were less likely to be profoundly apprehensive, anxious, and tense.

TABLE 2.—*Roentgenograms of Cervical Spine Recommended in Whiplash Injury*

View	Look for
Anteroposterior	Tilting, fracture, or dislocation
Lateral	Straightening of curve, fracture or dislocation
Lateral flexion and extension	Subluxation
Right and left oblique	Narrowing of foramen or fracture of lamina

Emergency hospitalization was advised in the case of an acute injury whenever a patient was emotionally disturbed, had a moderate concussion, or was known to have a subluxation, fracture, or dislocation of the cervical spine. In this series 23 patients were treated in hospitals.

In the case of an acute, mild, or moderate whiplash injury, the patient was usually managed at home. Rest in bed was advised for 24 to 72 hours. Most patients were more comfortable in a firm bed, and usually it was necessary to place a bedboard between the mattress and springs. Analgesics were necessary in all cases and were most effective when prescribed at regular intervals during the day for a stated period of days. Sedation during the day and at bedtime was necessary for the first few days. When the neck symptoms were intense or when cervical radiculitis was a prominent feature, a comfortable cervical collar support was prescribed for about two weeks. It was considered important for the patient to wear this collar intermittently. In our experience, constant wearing of a neck support results in atrophy of the cervical muscle and adds the complicating factor of weakened cervical muscles to the patient's problem. Later in the convalescence, the collar was worn when the patient was likely to jar his neck, such as when riding in a car, walking over rough ground, and at the end of the day, when fatigue of the neck muscles was most pronounced. Our experience corresponded with that of Eastwood and Jefferson who state that neurosis increases with the increase in efficiency of immobilization.[3] In cases of protracted muscular spasm, warmth was directed to the neck several times a day. We felt that intense heat increased muscular spasm and exaggerated rather than relieved the patient's discomfort. Warmth was applied by means of an ordinary floor or table lamp with a 100 watt bulb or an infra red bulb. The lamp was placed at least 2 ft. (60.96 cm.) away from the neck so that the patient experienced only a warm breeze on the back of the neck. Standing in a warm shower, the use of an electric heating pad adjusted to the lowest temperature, or application of warm moist towels to the neck were other measures available in the home.

In the severer instances of muscular spasm and radiculitis, it was useful to instigate cervical traction. A Sayre-type of head halter was purchased from a local hospital supply company. Patients were usually very resourceful in rigging the traction apparatus with sash cord or chain, pulleys, and a pail of sand for a weight. About a 7 lb. (3.2 kg.) weight provided satisfactory traction and was easily tolerated by the injured person. Cervical traction provided enforced rest and reduced muscular spasm. Since most of these patients experienced marked nervous symptoms, it was found that an intermittent program of traction best served the interest of the injury and the person. Two hours in traction and two hours out were advised during the acute phase of the illness, and one hour of traction several times a day was found useful later in the convalescent period. Anticonvulsants, such as diphenylhydantoin (Dilantin) sodium and phenobarbital, were prescribed for patients who had a moderate cerebral concussion.

Symptoms of tension were sometimes combatted by the use of warm baths.[4] The patient was advised to stretch out in a warm bath in which the water had been regulated to exactly 98 F according to a bath thermometer. Hydrotherapy was prescribed at least twice a day for a minimum of 20 minutes each time. Such treatment before bedtime promoted sleep and reduced the neuromuscular tension. Another important factor in management of the nervous patient consisted of control of daily activities. It was important to insist on regular rest periods each day and to limit activities to essential tasks. These patients were encouraged to participate in some manual activities that distracted them from preoccupation with the injury, reduced the neuromuscular tension, and improved morale. When a year or more had elapsed after an injury, it was our impression that the legal aspects of the injury were sometimes contributing factors in the psychoneurotic reaction. In those instances, it was advised that legal settlement be consummated.

In general, those persons who had signs and symptoms of a protruded intervertebral disk or roentgenographic evidence of a subluxation, dislocation, or fracture of the cervical spine required more extensive treatment in the form of hospitalization, cervical traction, and neck support. When these complications occurred, the services of a neurosurgeon were promptly requested.

CAUSE AND PREVENTION

The details of each accident were unusually complete in our records because 33 patients (66%) had threatened, started, or completed legal action in connection with the accident. A rear collision between two vehicles was responsible for the injury of 45 persons (90%). In 43 of these, only one car was moving, while, in the other 2, both were moving. Almost all of these accidents (39 out of 45) occurred near an intersection when the car ahead stopped to observe a traffic signal. Four other collisions were head on or from the side. The driver of the offending car was alleged to have been drunk in only two instances. All types of collisions numbered 49 and in only 6 of these cases was a truck or bus at fault. The other accident in this series involved only one automobile.

We were impressed in our experience with these patients by the importance of preventing accidents that commonly cause whiplash injury of the neck. The symptoms from this condition were so tenacious and the rate of recovery so slow that it was felt that every effort should be made by public authorities to prevent this kind of suffering. Drivers in many states are instructed to "drive ahead"; this means that they should observe what is happening some distance in front of their car so that they can anticipate changes in traffic conditions. To this advice should now be added the instruction to "drive behind"; this means that a motorist should keep the driver behind informed of stops and turns by the use of proper hand signals and that he should watch the driver behind him in the rearview mirror to be certain that these signals are observed. Some of the suggestions that may be useful to motorists are listed here. 1. Keep brakes in good condition. 2. Stay a safe stopping distance behind the car ahead. 3. Be alert for sudden changes in traffic conditions, especially a quick stop by the car ahead. 4. Allow a car that follows too close to pass. 5. Make use of proper hand signals to indicate stops and turns. 6. When stopping, observe driver behind in rearview mirror to be sure your signal is seen. If it is impossible to prevent a collision from behind, the best protection can probably be obtained by covering and supporting the head and neck with the arms or by falling in this same protected posture across the seat of the car.

REPORT OF CASES

Case 1.—While riding in the right front seat of a passenger car during July, 1951, the car in which this 47-year-old housewife was riding was struck from behind by a faster moving vehicle. The impact snapped her head and neck forward and backward several times. She was not unconscious but had severe pain in the neck and suspected that her neck was broken. Immediately after the accident, there was spasm of the cervical spinal muscles, limitation of motion, and tenderness of the lower posterior cervical region. Roentgenographic examination of the cervical spine was normal, and the neurological examination revealed no additional abnormalities. A program of rest was advised that included sedation and cervical collar support. In the weeks that followed, the woman experienced moderate nervous symptoms consisting of tension, restlessness, head sensations, moodiness, and general nervousness. Nineteen months after the accident, it was estimated that she had obtained only 80% recovery.

Case 2.—About August, 1950, this 44-year-old store manager stopped at a traffic light when her car was struck from behind by a semitrailer truck. She remembered the forceful snapping of her head forward and backward; she was bewildered but suffered no other injury. At the scene of the accident, she noticed aching of the neck and lower back. These symptoms persisted, and a few days later excessive fatigue, insomnia, generalized headache, subjective vertigo, and paresthesias in the right arm developed. She was first examined by one of us almost a year after the accident. At that time, there was hyperirritability of the neuromuscular system and tenderness and limited motion of the neck. Roentgenograms of the cervical spine, which were taken soon after the accident, were reviewed and found to be normal. It was concluded that she was suffering from a chronic sprain of the neck, with a mild concussion syndrome. There was definite evidence in the history that the woman had also had occasional cervical radiculitis involving the right arm. In the fall of 1950, definite nerve root pain developed in the left arm, and the neck symptoms became intensified. Later examinations revealed more marked limitation of the motion of the neck, tenderness of the spinous processes of the lower cervical vertebrae, hyporeflexia of the brachioradialis and biceps reflexes on the left side, weakness of grip of the left hand, and an area of hypesthesia over the dorsum of the left forefinger. A protruded intervertebral disk in the cervical region was suspected. Myelography performed in November, 1951, indicated a protruded disk at both the fifth and sixth interspaces on the left side. A conservative program was followed that consisted of cervical traction, application of warmth to the neck, use of a bedboard, administration of analgesics, limitation of activities, and wearing a comfortable neck collar support (all accompanied by an abundance of reassurance). Signs of nerve root compression disappeared in a few months. Thirty months later, it was estimated that there was about 75% recovery. The lack of complete recovery was largely because of a mild psychoneurotic reaction.

Case 3.—A 28-year-old housewife stopped at an intersection to observe a traffic light; her car was struck from behind by another passenger vehicle. She was momentarily unconscious. Profound pain was experienced in the neck, and the woman was forced to hold her neck rigidly in order to prevent aggravation of discomfort. Some pain radiated into the region of the right lower jaw and across the upper anterior chest wall on the right side. Roentgenograms of the cervical spine were normal. In the days that followed, insomnia, headache in the right frontotemporal region, syncope attacks, subjective vertigo, irritability, tension, and general nervousness developed in addition to pain, tenderness, and limitation of motion of the neck. When she was examined in June, 1951, two months after the accident, the neurological system was normal. She had evidence of a subsiding sprain of the neck and was considered to have a concussion syndrome. An electroencephalogram performed on June 7, 1951, was normal. The woman was treated with sedation, rest, and a comfortable cervical collar support and required an unusual amount of reassurance. In the interval of 22 months after the accident, she recovered approximately 75%. In our opinion, complete recovery was delayed by the development of a mild, chronic anxiety tension disorder.

Case 4.—About September, 1951, a 45-year-old interior decorator was a passenger in a taxi cab when the taxi was involved in a collision. The woman's knees were thrust against the back of the front seat, and both her neck and lower back were thrust forward in acute flexion. She was not unconscious but was shaken up. About an hour later, a sensation of tension developed in the back of her neck, and, for several days, she was irritable, restless, tense, and nervous. She noticed that bending her neck caused discomfort. An examination conducted about a month after the accident showed a generalized hyperreflexia and moderate limitation of motion of the neck. It was concluded that the woman had a sprain of the neck and mild cerebral concussion. One month later, she experienced some pain and paresthesias in the right arm. An examination showed hyporeflexia of the brachioradialis and biceps reflexes on the right side. Low back and right leg pain developed and was accompanied by muscular spasm in the lower lumbar region. These findings were interpreted as moderate cervical and lumbosacral radiculitis. There was insufficient evidence on clinical grounds to report a protruded disk in those regions. During the period of observation, the patient was treated with warmth supplied to the neck and low back, cervical traction at home, comfortable neck collar support, sedation, and sleep on a firm bed. Thirteen months after the accident, she had recovered completely.

Case 5.—A 33-year-old engineer was seated between the driver and another passenger when the car in which he was riding was involved in a head-on collision with another vehicle. Anticipating the crash, he braced himself and turned to the right to protect his daughter from possible injury. He was not unconscious but, immediately after the accident, noticed pain in the back of the neck that radiated into the left shoulder and arm as far as the thumb and forefinger. A few hours later, he experienced pain in the lower back; this radiated into the left hip and lower leg. All these symptoms persisted, and the man became disabled because of the low back and left leg pain. Lumbar traction and other conservative measures under hospital conditions failed to lessen his disability. The clinical findings and myelography indicated a protruded intervertebral disk at the fifth lumbar interspace on the left side. A cervical protruded disk was also suspected on the left side between the fifth and sixth cervical vertebrae. Laminectomy was performed, and a protruded intervertebral disk at the fifth lumbar interspace on the left side was found and removed. During the period of convalescence after the laminectomy, cervical traction was instituted for persistent low cervical and left upper extremity pain. On discharge from the hospital, most of the therapy was directed toward symptomatic relief of cervical radiculitis. Three months after the injury, the patient had recovered completely and was able to return to work. There have been only minor recurrences of the cervical radiculitis since that time.

RESULTS

Only 12 patients were examined by us within a few hours or days after their accident. The other 38 were first seen from one to 24 months after they were injured. In general, those persons who were managed a few hours or days after their injury improved more rapidly and their recovery was more complete. In our opinion, this difference in result was largely due to the personal attention that was provided, including discussion of the condition, reassurance, and a detailed program for relief of symptoms. The object of such attention was largely designed to prevent the development of a severe or intractable psychoneurotic reaction that would handicap full recovery.

There were 37 patients (74%) who were seen after their first examination. These patients were reexamined from 1 to 21 times. A detailed questionnaire sent out in February, 1953, was answered by 23 persons. The lapse of time between the accident and our last contact with the patient ranged from one month to five years. All 37 patients who were seen more than once were improved (30 cases, or 81%) or well (7 cases, or 19%). A study of the 30 persons who improved indicated that recovery was delayed by a psychoneurosis alone in 16, by a somatic condition alone in 3, and by a combined somatic condition and psychoneurosis in 11. In those who improved, 22 out of 30 were considered to have progressed to at least 75% of full recovery. These statistics supported the clinical impression that a whiplash injury is a chronic condition in which recovery is slow and the complication of a psychoneurotic reaction is common.

COMMENT

From the clinical standpoint, there are multiple organic pathological factors involved in radiculitis that follows a whiplash injury. It is reasonable to assume that there is trauma of the spinal ligaments because of the characteristic symptoms of a sprain of the neck, and, in some severe ligamentous injuries, an actual subluxation can be demonstrated by roentgenographic examination. It is likely that there is some hemorrhage and edema in the region of the damaged ligaments that may be a source of nerve irritation. Later on, fibrosis and cicatricial changes may be a chronic source of irritation of the nerve roots. At the instant of the whiplash, direct trauma of the nerve roots from stretching, compression, or even trauma of the spinothalamic pathways in the lateral columns of the spinal cord might conceivably occur.

In the acute case, swelling and vascular congestion of the nerve root and narrowing of the foramen due to protrusion of the intervertebral disk or swelling of adjacent ligaments may be important factors producing symptoms. In chronic cases, fibrosis, which is the late counterpart of hemorrhage and edema, may involve the nerve root directly, produce adhesions between the spinal ligaments and the nerve root, or cause a relative narrowing of the vertebral foramens. An additional factor may be the abnormal mobility of the vertebral joints because of damage of the ligaments.

Vertigo, which is described as part of the postconcussion syndrome and which may be due to vasomotor instability, might instead be due to a disturbance of the vestibulospinal system through either direct nerve root irritation or chronic abnormal hypertonicity of the cervical spinal muscles (tonic neck reflex system).

The presence of the vertebral artery as an integral structure of the upper cervical spine, with its investment of sympathetic nerve fibers, raises the question of the participation of the sympathetic nervous system (afferent or efferent) in the production of symptoms after a whiplash injury.

Headache has been mentioned as a symptom that follows a concussion. This may also be secondary to the pathological changes in the neck, either a referred pain from nerve or muscle sources or a reflex vascular phenomenon elaborated through the sympathetic nervous system.

These clinicopathological conditions are very difficult to prove, but a study of patients who suffered from persistent pain many months after their accident suggests that the original injury and late secondary organic changes are, in fact, severer and more complicated than have generally been supposed among laity, legal authorities, and physicians.

Beside the organic pathology of the whiplash injury, there is always the ever-present personal reaction of the patient that particularly complicates evaluation of symptoms, treatment, and recovery. It seems to us that, in addition to the factors already discussed, injury of the head and neck is of particular significance to the patient. These patients as a group are much more apprehensive, tense, and anxious than those suffering injury elsewhere in the body. We suspect that injury of the head and neck represents a special insult to the personality structure of the injured person.

The fact that more women than men, more housewives than any other occupational group, and more persons between the ages of 30 and 50 were injured gives rise to many speculations regarding the causes of whiplash injuries. Most of the speculations having to do with factors such as alertness, sex, age, skill in driving, and degree of exposure to traffic hazards cannot be proved. It is reasonable to state, however, that the collision from behind, which causes most whiplash injuries, is definitely the product of high speed motor transportation, increasing traffic congestion, and mounting traffic restrictions in the form of signs, lights, signals, and regulations.

SUMMARY

Fifty patients who suffered a whiplash injury of the neck were studied. These patients received a sprain of the neck that was often complicated by associated conditions. Characteristically, these patients were more disabled and remained handicapped for longer periods than was anticipated, considering the mild character of the accident. A majority of patients were injured in collisions from behind occurring when the first vehicle stopped to observe a traffic light. The findings in these 50 cases are reported, and a program of treatment is outlined. Some suggestions are made for motorists in the interest of preventing whiplash injuries.

ANALYSIS OF ONE THOUSAND CONSECUTIVE RESIDENCE VISITS TO ACUTELY ILL MEDICAL PATIENTS

William T. Couter, M.D., Alvin T. Held, M.D.
and
Charles L. York, M.D., Decatur, Ill.

Although residence visits may occupy a large share of a physician's working day, statistical knowledge concerning these visits is largely a matter of conjecture and hearsay. This study was inspired by a great variation in opinion among the older practitioners in our community regarding their impression of residence visits. We felt that by analyzing 1,000 consecutive residence visits some useful, and to a large extent unknown, statistical information could be obtained.

In order to make such a study, its basic unit—the residence visit—had first to be defined and then that definition rigidly followed. All patients 13 and under were automatically excluded. As far as was possible over the phone, complaints belonging to specialties other than internal medicine were referred to other practitioners, and only the remainder were then seen. Only the initial visit to any patient with a medical complaint or to the same patient for a medical complaint unrelated to a chronic condition was counted; the entire series was also screened to prevent any duplication in patients. The day of the call cards were completed by each of us, and these cards then formed the basis of the study. These cards contained spaces for the name, age, and sex of the patient, as well as the time and date of the call, drugs used, diagnosis, and an evaluation of the need of the call. At regular intervals the cards were checked to determine any changes in the initial diagnosis, which might have been clarified by time. For instance, an initial impression of gastroenteritis in one patient became a proved lymphosarcoma of the stomach later, and the card was changed to the final and correct diagnosis. One hundred and seventy-nine patients were hospitalized (an additional 48 patients needed but refused hospitalization) and received laboratory work as needed for diagnosis. The remainder of the patients with nonevanescent conditions were seen either on subsequent visits or in the office, with outpatient laboratory work as deemed necessary. This study was started in November, 1950, and completed in March, 1953. It represents 29 months of residence visits for two of us (W. T. C. and C. L. Y.) and 15 months for one of us (A. T. H.), or an aggregate of 73 months of residence visits. This period of time becomes important, in that for half of the patients there is a follow-up period of at least 15 months and for three-fourths a similar period of at least 8 months.

One of the most interesting facts to emerge from this study was the preponderance of female patients requiring residence visits. The over-all percentage of female patients was 65.5% as compared to 34.5% for male patients. All three individual series were in close agreement: 68.9% female (A. T. H.), 66.6% female (C. L.Y.), and 63.3% female (W. T. C.).

To some extent the time that the residence visit was made was weighted by the fact that we try to make such visits in the morning while en route to or from the hospital and in the evening after office hours. For the purpose of the study all seven days were assumed to be equivalent. There were 325 visits from 7 to 12 a. m., 311 from noon to 6 p. m., 206 from 6 to 8 p. m., 111 from 8 p. m. to midnight, and 47 after midnight.

In our discussion prior to embarking on this study, there was a universal cynicism about the urgency of the visit after midnight. Yet in these 47 screened calls, 15, or 31.9%, required a physician within 4 hours; one additional patient should have been seen within 12 hours. Twenty-seven patients were symptomatic but not urgently so and from the physical symptoms only could have been seen the following morning; however, the emotional impact of disease occurring after midnight in particular cannot easily be resolved over a telephone. We felt that the remaining four patients needed neither physical therapy nor emotional reassurance at that hour. There were 27 visits to female patients and 20 to male

---

Presented at the Southern Illinois Regional Meeting of the American College of Physicians, Bloomington, Ill., March 21, 1953.

patients, a female preponderance of 57.3%, which is not too far removed from the over-all female majority. There were 26 diseases among the 47 visits: appendicitis (1), anxiety state (2), bronchial asthma (1), acute back (1), bronchiectasis (1), bronchitis (1), bronchogenic carcinoma (1), Laennec's cirrhosis (1), cerebrovascular accident (2), cholecystitis (2), collapsed vertebral body (1), congestive heart failure (7), coronary occlusion (3), dysmenorrhea (1), acute failure of the left side of the heart (dead on arrival) (1), hypertensive epistaxis (1), gastroenteritis (4), hyperventilation (1), fractured ribs (1), "influenza" (3), migraine (1), pneumonia (4), pleurisy (1), renal colic (1), tonsillitis (3), and urinary tract infection (1).

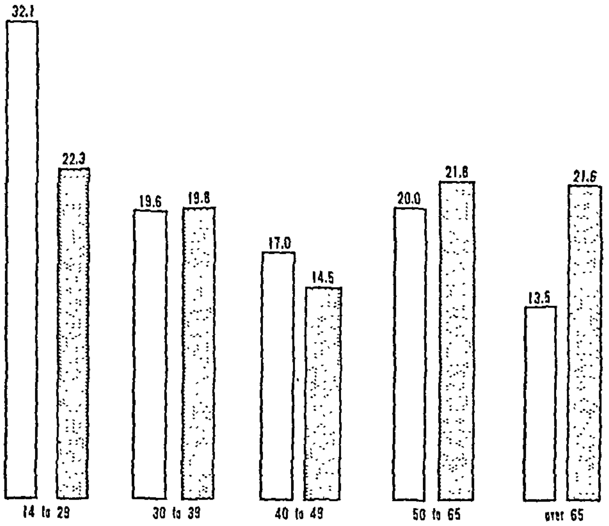
The patients were classified into five age groups—namely from 14 through 29, 30 through 39, 40 through 49, 50 through 65, and finally over 65 (see figure). The statistical incidence of each age group was then compared against its population density, as computed from the 1950 census of Macon County. The imbalance, stressing the high incidence of visits to those over 65, serves to emphasize the importance of geriatric medicine.

Our primary purpose in analyzing these residence visits was to determine, if at all possible, the actual need for such a visit. Early in the study we concluded that we were not competent to answer this question; we could not be objective enough in our evaluation, and we were not able to assess the value of reassurance for a seemingly trivial complaint. We assumed that a physician's presence was necessary for the patient, which nullified our original question of "Is this call necessary?" We substituted the question "Could this patient have been seen in the office?", and this question we could answer with a greater degree of objectivity and accuracy. We were then able to place our patients into four groups. In the first were those patients whose complaints were of such a nature that a residence visit within four hours of receiving the call was necessary, and in this group were 8.2% of the total calls. In the second group were those patients whose complaints could tolerate a 12 hour time lag, and in this group were 4.3% of the total visits. The largest group, 62.6%, was composed of those patients who had symptoms but whose complaints were not urgent and who for various reasons were unable to visit the office; in this group was included, for instance, a mildly ill mother taking care of three children and without a baby sitter. The fourth group was a controversial group and was composed of those patients we felt could easily have been seen in the office, and this group comprised 24.9% of the total. The individual series for this last group reflect the difficulty in evaluating a patient's need: two of us were in close agreement (A. T. H. 17.8% and C. L. Y. 18.4%), as compared to the 28.9% of our third member (W. T. C.).

We were interested in trying to determine whether there was any shift in the sexual predominance in any of these four groups. The over-all percentage was that of 65.5% female and 34.5% male. In the group of 249 patients that we felt were able to visit the office, there were 66.6% women and 33.4% men. In the large group of patients with nonurgent symptoms requiring a residence visit 68.8% were women and 31.2% were men. In the 43 patients requiring a visit within 12 hours 68.2% were women and 31.8% were men. It was only in the group that needed a visit within four hours that a shift in the general pattern was present, for in this group of 82 patients only 46.3% were women, as compared to 53.7% men.

There were 135 different clinical entities encountered during the 1,000 residence visits. Fourteen of these entities covered 66.4% of the total calls, leaving 121 others distributed throughout the remaining 336 visits. The commonest entities in the order of their occurrence were: "influenza" 148, follicular tonsillitis 84, nasopharyngitis 79, pneumonia 70, gastroenteritis 67, anxiety state 51, cardiac failure 36, bronchitis 25, acute back pain 23, urinary tract infection 23, coronary artery disease 22, cholecystitis 20, cerebrovascular accident 15, and bronchial asthma 15 (see table).

The diagnosis "influenza" was used to classify a clinically repetitive pattern of illness occurring in our community in 1952-1953. This group was differentiated from the nasopharyngitis group by the severity of the acute symptoms and more importantly by the prolonged postinfectious asthenia. In the 1,000 acutely ill patients primary cardiac disease was discovered only 70 times, or in 7%; however, 27 of these patients were hospitalized (another 10 needed but refused hospitalization); this group formed 16.3% of the total hospitalized group. In the neuropsychiatric group there were 67 women and 36 men: the female percentage of 65.0% is in close agreement with the over-all female percentage of 65.5%. The ruptured ectopic pregnancy deserves special mention, as several days previously the patient had passed a complete fetus and the possibility of a combined uterine and tubal pregnancy was initially almost ignored.



Comparison by percentage of age groups requiring residence visits as against the population density, according to the 1950 census. Shaded bar denotes total residence visits.

On four occasions the patient died prior to our arrival. On each of these occasions the telephone summons was so urgent that the call was answered within 15 minutes. One patient died of bronchial asthma and the other three of acute failure of the left side of the heart.

A disconcerting paucity of neoplastic disease was encountered in the series. The comparatively long period of time occupied by this study becomes important now in evaluating our low incidence. We discovered four primary neoplasms: a squamous cell carcinoma of the throat, a lymphosarcoma of the stomach, and two bronchogenic carcinomas. It is entirely possible that some of the conditions encountered in the last six months may represent neoplastic disease in an occult form, but, judging from the follow-up studies on the remaining patients, any such changes will not add a significant number to the total.

Classification of the Diseases Encountered in 1,000 Consecutive Residence Visits

Site or Type of Disease	Number of Visits	Clinical Entities
Cardiorespiratory system	198	Pneumonia 70, cardiac failure 36 (rheumatic 3, hypertensive 7, arteriosclerotic 25, and cor pulmonale 1), bronchitis 25, coronary artery *disease 22 (coronary occlusion 12 and coronary insufficiency 10)*, bronchial asthma 15, pleuritis 7, paroxysmal auricular tachycardia 6, varicose ulcer 3, thrombophlebitis 3, uremia 2, paroxysmal auricular fibrillation 2, bronchogenic carcinoma 2, pericarditis 1, dissecting aneurysm 1, auricular flutter 1, bronchiectasis 1, and acute rheumatic fever 1.
Ear, nose, and throat system	191	Follicular tonsillitis 84, nasopharyngitis 79, labyrinthitis 10, sinusitis 9, otitis externa 2, otitis media 2, hypertensive epistaxis 2, conjunctivitis 1, *carcinoma of the throat 1*, and laryngitis 1.
Specific infectious diseases	158	"Influenza" 148, infectious mononucleosis 2, mumps 2, chickenpox 2, herpangina 2, rubella 1, and meningococcic meningitis 1.
Gastrointestinal tract	141	Gastroenteritis 67, cholecystitis 20, appendicitis 12, irritable bowel syndrome 9, bleeding duodenal ulcer 5, diverticulitis 4, small bowel obstruction 4, hemorrhoids 3, rectal impaction 3, perforating duodenal ulcer 3, large bowel obstruction 2, anal fissure 2, obstructed duodenal ulcer 2, esophageal stricture 1, lymphosarcoma of the stomach 1, bleeding gastric ulcer 1, Laennec's cirrhosis 1, and hepatitis 1.
Neuropsychiatric	103	Anxiety state 51, alcoholism 14, hyperventilation syndrome 13, senile dementia 7, chronic fatigue syndrome 5, conversion hysteria 5, barbiturate intoxication 4, reactive depression 3, and menopausal psychosis 1.
	52	Cerebrovascular accidents 15, hypertensive encephalopathy 12, migraine 10, epilepsy 4, collapsed vertebral body 4, peripheral neuritis 4, transverse myelitis 1, concussion 1, and electric shock 1.
Musculoskeletal system	51	Acute back pain 23, myositis 7, sprains 7, fractures 5, dislocations 3, bursitis 3, rheumatoid arthritis 2, and osteoarthritis 1.
Skin	36	Contusions 8, urticaria 6 (of which 3 were penicillin urticaria), herpes zoster 4, paronychia 4, dermatitis medicamentosa 4, cellulitis 3, lacerations 2, dermatitis venenata 1, sunburn 1, infected eczematoid dermatitis 1, erythema multiforme bullosum 1, and furuncle 1.
Genitourinary organs	32	Urinary tract infection 23, renal colic 6, prostatism 2, and postoperative urethral stricture 1
	22	Pelvic inflammatory disease 6, dysmenorrhea 4, fibroids 2, pregnancy 2, intermenstrual pain 2, attempted abortion 1, ruptured ectopic pregnancy 1, menopausal bleeding 1, senile vaginitis 1, relaxed pelvic floor 1, and *endometriosis 1*.
Endocrine organs	7	Insulin reaction 3, acute gout 2, prediabetic coma 1, and heat exhaustion 1.
Miscellaneous	9	Periapical abscess 3, postviral asthenia 2, pernicious anemia 2, and angioneurotic edema 2.

Decatur, a city of about 70,000 population, has a strong tradition of residence visits, and a well-used bag is a part of both the general practitioner's and specialist's basic armamentarium. Most of the drugstores close in the early evening, and all are closed by 11 p. m. The working pharmacopeia then has to cover the nonhospitalized patient until a complete therapeutic battery is available the following morning. We have found that the following 16 drugs were used the most frequently: aspirin compounds (364), penicillin with or without streptomycin (we carry both) (291), soporifics (216), barbiturates (188), meperidine (Demerol) hydrochloride (92), Triple Sulfas suspension (combination of sulfadiazine, sulfamerazine, sulfamethazine, and alcohol) (44), cough syrup (39), morphine (36), aminophylline intravenously (32), meralluride (Mercuhydrin) sodium (24), sodium salicylate orally and parenterally (19), dihydroergotamine methanesulfonate (D. H. E. 45) (14), dimenhydrinate (Dramamine) parenterally (12), Kaopectate (adsorbent for intestinal dysfunction) (11), diphenhydramine (Benadryl) hydrochloride parenterally (10), and codeine orally (10). The amount of soporifics utilized is weighted by the fact that one of us (W. T. C.) dispenses a small amount of secobarbital (Seconal) on many of his visits. All three of us consistently used more meperidine hydrochloride than morphine. The dihydroergotamine methanesulfonate and diphenhydramine hydrochloride were consistently employed together in migraine; the dimenhydrinate was used in the same syringe with meperidine hydrochloride for gastroenteritis.

There were 14 drugs that were used sparingly but whose presence in the bag was vitally necessary. These were digitoxin orally and parenterally (8), camphorated opium tincture (7), amobarbital (Amytal) sodium parenterally (4), epinephrine (Adrenalin) in oil (4), atropine parenterally (4), quinidine orally (3), glucose intravenously (2), methantheline bromide (Banthine) parenterally (2), pentylenetetrazol (Metrazol) (1), nitroglycerin (glyceryl trinitrate) (1), procaine amide (Pronestyl) hydrochloride intravenously (1), neostigmine (Prostigmin) parenterally (1), calcium gluconate parenterally (1), and methantheline bromide orally (1).

All of us have had experience with drugs that have been carried uselessly in the bag for years prior to final discard. We carried camphor in oil, aqueous epinephrine, coramine (25% solution of nikethamide) caffeine and sodium benzoate, and methylisooctenylamine (Octin) for a total of 73 months without finding a suitable indication for their use in these acutely ill patients.

SUMMARY

One thousand consecutive residence visits to acutely ill medical patients are analyzed as to the sex and age of the patient, the time and necessity of the call, the diagnoses established, and the drugs utilized.

250 N. Water St. (Dr. Couter).

Achalasia.—In an examination of the gullets of thirteen patients who died suffering from achalasia, Lendrum found that the only deviation from normal was that the ganglion cells of Auerbach's plexus were always deficient or absent. Due allowance was made for the fact that the cells are more scarce in a distended gut. Lendrum stated that the deficiency affected the dilated part of the gullet as well as the narrow segment. These findings have been confirmed by many competent pathologists; and it may be that, in the light of the work upon Hirschsprung's disease, the deficiency of ganglion cells in the narrow segment may be the key to understanding achalasia. Achalasia and Hirschsprung's disease could be comparable diseases.—N. R. Barrett, M.D., Achalasia: Thoughts Concerning the Aetiology, *Annals of the Royal College of Surgeons of England,* June, 1953.

USE OF OCTAMETHYL PYROPHOSPHORAMIDE IN THE TREATMENT OF MYASTHENIA GRAVIS

FURTHER OBSERVATIONS

Sidney Schulman, M.D., J. Alfred Rider, M.D., Ph.D.,
and
Richard B. Richter, M.D., Chicago

Octamethyl pyrophosphoramide (OMPA) is the most recent organic phosphorus anticholinesterase agent used in the treatment of myasthenia gravis. The pharmacology of this drug has been extensively studied by DuBois, Doull, and Coon.[1] It is not itself an active antisterase agent, but it is converted to an active substance by the liver. Like the other organic phosphorus compounds, such as di-isopropyl fluorophosphate and tetraethyl pyrophosphate, and in contrast to neostigmine, the active metabolite of octamethyl pyrophosphoramide inhibits cholinesterase irreversibly. It is for this reason that all of these compounds have the advantage over neostigmine of a longer duration of action. The advantages of OMPA over the others lie in its greater chemical stability and less severe toxic side-effects. Muscarinic symptoms from octamethyl pyrophosphoramide are more easily controlled with atropine than are those produced by di-isopropyl fluorophosphate and tetraethyl pyrophosphate, and, furthermore, OMPA, because of its exclusively peripheral action, does not cause the central stimulant effects that the others do.

Octamethyl pyrophosphoramide is taken orally in a 1% solution in propylene glycol. Two daily doses given at 12 hour intervals have been sufficient to maintain strength evenly in most of our patients, but a few persons have required a small midday dose in addition. The transfer from neostigmine to OMPA is accomplished while the patient is in the hospital. First, a small dose, 5 to 7 mg. twice a day, is given and it is gradually increased. At the same time, neostigmine is given as necessary only until it is no longer required at all. Generally, it is possible to replace neostigmine in this way in one or two weeks. Although in most of our patients serum and red blood cell cholinesterase determinations were made daily during the period of transition this is not necessary, and, in fact, once a maintenance dose of the substitute drug has been established, such determinations are of little value, because the blood esterase levels no longer closely reflect the theoretical esterase depression at the myoneural junction. It is known, however, that the full therapeutic effect of octamethyl pyrophosphoramide is not achieved unless the red blood cell esterase activity is well below 10% of normal.

EARLIER RESULTS

We reported the results of the treatment of the first six patients who received OMPA in 1951.[2] Since then two more reports have appeared in the literature by others who have used the drug, and both groups have said that it is the most satisfactory agent now available for the management of myasthenia gravis.[3] Our own experience at the time of our initial report led us to conclusions that were not this sanguine, and, with further experience, we are even more certain that octamethyl pyrophosphoramide cannot be endorsed as a substitute for neostigmine without strong reservation.

Our total experience with this drug includes its use in 15 patients. Of this number, seven are now dead and two were unable to make the change from neostigmine to OMPA. The mortality in this series, therefore, approaches 50%, and, if the two patients who could not tolerate the drug are excluded from the total, it is slightly more than 50%. This is certainly a higher mortality than would be expected in a similar group of myasthenic patients treated with neostigmine, even considering that the selection in this series was in favor of severe cases. Our results then, when they are stated in this way, not only would appear to indicate that OMPA is no more effective than neostigmine in cases of severe myasthenia but also raise the questions of whether the drug itself might cause death, and, if so, whether its use should be continued at all in the treatment of myasthenia gravis. It is with the purpose of providing an answer to these questions that the following analysis is presented.

Of the seven patients who died, we think there is good reason to believe that four died in myasthenic crisis and three from direct intoxication by the drug. In reviewing the fatal cases in the order of decreasing probability that the drug was responsible for death, it is possible to begin with one patient whose death was unquestionably caused by the drug.

DEATHS CAUSED BY OMPA

This patient was a 37-year-old woman with severe myasthenia gravis and a thymoma. She apparently had had an undiagnosed, rapidly progressing myasthenia for a year by the time she was first seen at Billings Hospital, in October, 1950. At that time she was in rather critical condition because of advanced bulbar and respiratory weakness. She was treated with neostigmine, 300 mg. daily, for six months with results that were at first fairly satisfactory but that soon became more and more disappointing. In May, 1951, therefore, neostigmine was replaced by OMPA in a maintenance dose of 16 mg. in the morning and 15 mg. at night. The patient's strength on receiving OMPA was about the same as it had been when the effect of neostigmine was at its height, but there was no question that she was benefiting more from the substituted drug because of its sustained action. She was no longer awakened

Med. **37**: 574 (Sept.) 1952. (*b*) Gregory, L., Jr.; Futch, E. D., and Stone, C. T.: Octamethyl Pyrophosphoramide in Therapy of Myasthenia Gravis, Am. J. Med. **13**: 423 (Oct.) 1952.

during the night by dyspnea, as had frequently happened when she was taking neostigmine. She took 0.6 mg. of atropine four times a day to overcome mild muscarinic side-effects (cramps, diarrhea, and excessive perspiration). Except for the perspiration, this dose of atropine controlled the symptoms completely. During the next four months, however, she complained of increasing general weakness and of difficulty in chewing and swallowing late in the day, and she began to lose weight. For this reason, the dose of OMPA was gradually increased so that by the middle of September, 1951, three months after administration of the drug was begun, she was taking the unusually large amount of 24 mg. in the morning and at night and 8 mg. at noon, a total of 56 mg. daily. Apart from the size of the dose, however, there was no indication that a dangerously toxic level was being approached. On the contrary, although her course in general during this period was one of deterioration, there had been a transient improvement in her strength after each increase in the dose, and her requirement for atropine remained the same.

The patient was admitted to the hospital again in October, 1951, in the hope that thymectomy might benefit her. During her first two weeks in the hospital while she was on a program of bed rest and high caloric feedings, she improved appreciably and gained 5 lb. (2.3 kg.). The dose of octamethyl pyrophosphoramide was not increased but was maintained at 56 mg. a day. At this time it was felt that the patient could withstand a thymectomy, and the procedure was scheduled for late in October. There was some concern about the relative inflexibility of a large maintenance dose of OMPA during surgery. For this reason it was decided to ascertain the effect of small parenteral doses of neostigmine in addition to the established dose of OMPA, so that, if occasion should arise during surgery or the postoperative period for an attempt at rapid further depression of esterase, we would know beforehand what, if anything, might be caused by parenteral administration of neostigmine. We were well aware of the probability that neostigmine would not improve the patient's strength and that it would much more likely result in a toxic parasympathetic reaction and, perhaps, even an increase in weakness. We did not believe, however, that a cautious trial of small doses compensated by atropine would be excessively dangerous. It was found that a dose of 0.25 mg. of neostigmine given subcutaneously had no effect of any kind. A few days later, at 5:30 p. m., the patient was given 0.5 mg. of neostigmine and 0.4 mg. of atropine subcutaneously in the same syringe. During the next half hour, there was a distinct improvement in her strength, and, at 6 p. m., when she began to take her evening meal, she said that chewing and swallowing were easier than usual. At 6:15, however, 45 minutes after the injection, she began to feel generally weak. By 6:30 she was apprehensive and dyspneic, and, within the next 10 minutes, she became completely paralyzed. Oxygen and manual artificial respiration were given, and, although there were no signs of parasympathetic stimulation, she was given 0.6 mg. of atropine intramuscularly. At 6:45, the patient was comatose, and, by 7 p. m., the heart beat had stopped. Shortly before death there had been slight siallorhea, but there was no other evidence of a cholinergic reaction, in the ordinary sense, during the interval of an hour and a half between the injection of neostigmine and the woman's death. There were no abdominal cramps or diarrhea and no bradycardia, lacrymation, diaphoresis, or miosis.

There is little question that this patient died as a direct result of 0.5 mg. of neostigmine administered parenterally in addition to a high maintenance dose of octamethyl pyrophosphoramide and that death was due to generalized paralysis despite the suppression of muscarinic symptoms by atropine. It might be argued, of course, that, since neostigmine was the precipitating cause of death, OMPA should not be held responsible. Nevertheless, a dosage that transforms an ordinarily innocuous amount of neostigmine into a lethal dose is much too near the upper limit of safety to be accepted as a feasible method of treatment.

There were two other deaths that were in all likelihood from antiesterase intoxication, although they did not occur under observation in the hospital. These two patients were included among the favorable cases in our first report.[2] One of them was a young, energetic man living in the backwoods of northern Wisconsin, far from immediate medical attention. As our patient, he had been under treatment with neostigmine for a number of years. With time, however, his requirement for neostigmine increased until he was greatly handicapped by severe general and bulbar weakness, even while receiving large doses. In view of the severity of his symptoms and his inaccessibility, we were reluctant to give him octamethyl pyrophosphoramide, but finally decided to do so because of his repeated threats of suicide, which we regarded as serious. For several months he did very well on 27.5 mg. a day. He was able to enter again the activities of his circle of friends and to drive a truck for a living. Then his requirement for the drug increased; improvement of his symptoms followed each time the dosage was increased. We increased the dosage cautiously, with due warning to him and his local physician to be on the alert for toxic symptoms. We had reason to believe, however, that with the heedlessness of youth he was regulating the dose more or less to suit himself. Then one day, unexpectedly, six months after this form of therapy had been started, he was found dying. He died a few minutes after the arrival of his physician.

The other patient who died at home was a middle-aged man who had had myasthenia gravis for three years.[2] He had been leading a life of moderately restricted activity while receiving large doses of neostigmine. Octamethyl pyrophosphoramide, 18 mg. twice daily, resulted in a gratifying improvement. After the maintenance dose was established, however, the patient never returned to the clinic for follow-up supervision but kept us informed by mail. He soon increased the dose to 25 mg. twice a day, and later, despite our objections, he began to experiment with the dosage and to supplement it with neostigmine in an irregular way. This patient also died suddenly at home about six months after treatment with OMPA was begun.

CAUSES OF DEATH

The cause and nature of death in these three patients is deserving of special emphasis. We are quite certain, in the case of the first patient and reasonably so in the other two, that death was a result of rapidly developing, generalized paralysis precipitated by excessive inhibition of cholinesterase. In this connection, it has been known for some time that the phenomenon of complete block in neuromuscular transmission is part of the nicotinic action of acetylcholine.[4] This occurs when acetylcholine is present in excess at the neuromuscular junction. There is now ample experimental evidence that such an excess of acetylcholine and its consequence, fatal paralysis, can be produced in animals by large doses of the organic phosphorus anticholinesterase compounds.[5] It is also known that atropine has no influence on the nicotinic action of acetylcholine and that it is, therefore, not an antidote to this phase of antiesterase toxicity. In fact, in most animal species, it is only after the suppression of the lethal muscarinic effects of acetylcholine by the use of atropine that the independently lethal nicotinic action becomes apparent. Theoretically, it would seem possible to overcome nicotinic neuromuscular block by the administration of a drug having a curare-like action. Curare itself has been reported to be ineffective in this respect in animals poisoned with di-isopropyl fluorophosphate,[5a] but magnesium sulfate does protect such animals to some extent if it is given before paralysis develops.[6] On the other hand, if magnesium sulfate is given after flaccid weakness appears, it is apt to precipitate death.[5a] Apparently the chemical equilibrium involved is so critically poised that attempts to influence it pharmacologically are far too crude to be successful, and they are obviously inapplicable in myasthenic patients in whom the problem is further complicated by a primary defect in neuromuscular transmission, the nature of which is still unknown.

---

[4] Rosenbleuth, A., and Morison, R. S.: Curarization, Fatigue and Wedensky Inhibition, Am. J. Physiol. 119: 236 (June) 1937.

The point we wish particularly to emphasize, in regard to myasthenic patients being treated with OMPA, is the insidious way in which this nicotinic toxicity can build up to the final, sudden, catastrophic collapse. We had expected, when we began treating patients with the drug, that toxic muscarinic symptoms would give ample warning of danger, but this has not been so. In general, once a maintenance dose of octamethyl pyrophosphoramide is established, our patients have shown no increased salivation, perspiration, or gastrointestinal symptoms with subsequent increases in the dose. This is probably accounted for by the facts that they were taking atropine as a regular part of their treatment and that much smaller doses of atropine are required to control muscarinic symptoms in patients receiving this agent than are necessary in those receiving di-isopropyl fluorophosphate or tetraethyl pyrophosphate. This offers no practical solution to the problem, however, for, although the atropine requirement is small, it has been necessary, for comfort's sake alone, for almost all of our patients to take some atropine if OMPA is given at all. With increasing weakness, then, as the only indicator of serious toxicity, one can say that it is always difficult and sometimes impossible to distinguish between an inadequate dose and one that is gravely toxic for a particular patient. It would appear that this margin may be a very narrow one indeed.

CAUSE OF DEATH DEBATABLE

Of the remaining four deaths, there was only one in which it might be argued that the drug was responsible, though in a less direct way than in the three patients already discussed. This case was recorded in our initial report as a myasthenic death. In view of possible alternative interpretation and because it illustrates another objectionable feature of OMPA, the pertinent details are repeated here.

A 30-year-old woman, with very severe myasthenia gravis that was poorly controlled with large doses of neostigmine, was brought to the hospital for treatment with octamethyl pyrophosphoramide more or less as a last resort. It was felt that she might benefit from the combination of a small maintenance dose of OMPA and a reduced amount of neostigmine. This compromise in management, which has been reported by others [3b] as useful in severe cases of myasthenia gravis, proved to be out of the question for this patient, because, after therapy was begun, severe nausea, cramps, and diarrhea followed each dose of neostigmine. These symptoms could not be controlled entirely with atropine, which was administered in amounts as large as she could tolerate, and they appeared when the dose of OMPA was quite small and when the blood esterase levels were only moderately reduced. For this reason and because of the patient's precarious existence on neostigmine alone, it was believed that an attempt to replace neostigmine completely with octamethyl phosphoramide would be justified. The dose was, therefore, slowly increased over a period of three weeks to 11 mg. twice a day. On this dose the red blood cell esterase activity was about 10% of normal, a level approaching but not actually within the full therapeutic range. Throughout the period of transition, neostigmine continued to produce severe muscarinic symptoms, but, although the requirement for neostigmine gradually diminished, small doses were always necessary to maintain sufficient strength for respiration and swallowing. Finally, after the second, 11 mg. dose of OMPA, neostigmine, for the first time, did not result in any increase in strength but seemed to make the patient distinctly weaker. Six hours after the second dose of OMPA was administered, complete respiratory paralysis developed. Tracheotomy was performed, and the patient was placed in a respirator. Administration of OMPA was discontinued, and neostigmine was withheld for 14 hours, after which it was found that small doses still had no beneficial effect. The woman died 48 hours after receiving the second 11 mg. dose of OMPA. A few hours before her death, the patient was given 3 mg. of neostigmine intravenously as a heroic measure. This had no apparent muscarinic or nicotinic effect.

In this instance, it would seem that either of two interpretations is possible. One is that this patient had severe myasthenia gravis that happened to become worse spontaneously and to cause the patient's death while an attempt was being made to establish a maintenance dose of OMPA. On the other hand, it is also possible to say that the drug contributed significantly to the woman's death in two ways: first, by interfering with the patient's nutrition and rest through the production of severe muscarinic symptoms in the long period during which both OMPA and neostigmine were being taken, and, second, by leading to the peculiar state existing in the last few days of life in which, apparently, the dose of OMPA was inadequate to sustain life and yet large enough to allow the further esterase depression produced by small doses of neostigmine to go beyond the optimum and to result in an increase in weakness rather than an increase in strength.

We believe that precisely this sort of disagreeable impasse was avoided in the two patients in whom it was impossible to substitute OMPA for neostigmine. In these patients, severe muscarinic symptoms developed without any increase in strength, during the process of substituting OMPA for neostigmine and at a time when the dose of OMPA was comparatively small and the blood esterase levels were only moderately reduced. Management of these patients on the combination of drugs was also impossible, but we chose to discontinue the use of OMPA entirely rather than to attempt to achieve the full therapeutic levels.

[6] Footnotes 5*a* and *b*.

Of the remaining three patients who died, all had severe myasthenia gravis. One died at home and two died in the hospital. One of these latter had taken the same dose of octamethyl pyrophosphoramide for two years before her death. In none of these three is it possible to say that the drug caused death except, in the two who died under observation in the hospital, there was the impression that, because of the lack of flexibility imposed by a full maintenance dose of the drug, nothing could be done to prevent death. Under such conditions, neostigmine is of no value and is even dangerous and it is impossible to make significant changes in the dose of OMPA quickly without danger of overdosage. In myasthenic crises in patients receiving neostigmine, on the other hand, one can at least give larger amounts of neostigmine without as much probability that death may result from the treatment.

COMMENT ON FURTHER USE

These seven fatal cases and the two living failures, then, obviously confirm the suspicions that octamethyl pyrophosphoramide is no better than neostigmine in the treatment of severe myasthenia gravis and that it can itself contribute directly to death, when given in the large doses that are required and tolerated with minimal muscarinic side-effects by some patients with severe myasthenia gravis. Whether, for these reasons, its use in myasthenia gravis should be discontinued entirely is another question, and it is one for which the answer should be based on evidence from our cases that responded favorably and from those in which OMPA was used successfully by others. At the present time, we have six patients who have been receiving the drug without neostigmine for periods of from seven months to two and one-half years. In all of these patients who had previously been taking neostigmine, we can say unreservedly that octamethyl pyrophosphoramide has been more satisfactory. While four of them have mild myasthenia gravis and two have only moderately severe cases, all have been much less disabled during therapy with OMPA than when they were taking neostigmine, and all are now leading active and useful lives. The average dose of OMPA among these patients is 20 mg. per day. The largest dose is 28 mg. daily, and all of them find it necessary to take 0.4 or 0.6 mg. of atropine three or four times a day to control muscarinic side-effects.

FAVORABLE RESULTS

Three patients, who have taken the drug for the longest periods of time, are briefly described as representative examples of this group. One of them, a 48-year-old woman who was accustomed to a very active social life and much traveling, was restive and discontent because her activities were so hampered while she was taking neostigmine. She has taken OMPA for two and one-half years and has been able to resume her former activities fully. The maintenance dose of the drug has never been greater than 18 mg. a day. In the summer of 1952, she managed her country house without servants and spent much time outdoors every day while taking a single dose of 4 mg. a day. At present she takes 9 mg. per day.

Another woman, 52 years old, whose disease has been somewhat more than mild, has been taking OMPA with satisfactory results for more than two years and has apparently stabilized the dosage at 28 mg. a day. During the period of her treatment, she underwent a total hysterectomy and, recently, took care of two active grandchildren.

The third patient, a 32-year-old man with comparatively mild myasthenia gravis, had been receiving neostigmine for five years. While the results were objectively satisfactory, he was greatly dissatisfied and made his own life and that of his family miserable by his bad humor. For that reason, he was treated with OMPA, which gave him maximum benefit in a dose of 28 mg. a day. He has been on this regime for more than two years, has been quite contented, and works regularly at his job with the city fire department.

In view of the excellent results in these patients, we find it very difficult to say, in spite of the hazards involved, that octamethyl pyrophosphoramide has no place in the treatment of myasthenia gravis and that its use should be abandoned.

SUMMARY AND CONCLUSIONS

This survey of the results of treatment of a group of 15 patients with myasthenia gravis with octamethyl pyrophosphoramide makes it quite clear that the very advantages of the drug, over the other organic phosphorus compounds and over neostigmine, can become serious disadvantages under certain circumstances. One of the advantages of OMPA over the other phosphorus compounds is that it produces muscarinic side-effects that are much more easily controlled by atropine. Thus, while it is true that nearly all our patients have had to take small amounts of atropine, subsequent increases in the dose of OMPA have not often required an increased amount of atropine. Since the action of an irreversible esterase inhibitor in myasthenic patients, beyond a certain critical point, leads to paralysis rather than to further increase in strength, the absence of muscarinic symptoms can be very deceptive, and situations may arise in which it is quite impossible to decide from the appearance of a patient alone whether an increase in weakness is a result of too much or too little of the drug. Furthermore, this toxic weakness can appear suddenly and progress rapidly to fatal, generalized paralysis.

Like the other organic phosphorus compounds, octamethyl pyrophosphoramide has the single advantage over neostigmine of a longer duration of action, and, as is also true with the others, the peak effect of a single dose is delayed for several hours. This combination of slow onset of action and prolonged effect, however, under conditions of myasthenic crisis, compares quite unfavorably with the flexibility provided by the rapid and reversible action of neostigmine administered parenterally.

We believe that OMPA does have a place in the treatment of myasthenia gravis, in spite of the hazards involved, but we cannot endorse its general use without strict qualifications. We think it should certainly be restricted to the treatment of the patient with mild or, at the most, comparatively mild symptoms and for whom neostigmine is not satisfactory. Also the patient should be intelligent and cooperative and should be watched carefully. It will sometimes happen that such a patient will do well on small amounts of the drug for a time, only to have his requirement increase later, just as with neostigmine. In these instances, repeated but temporary improvement may occur after each increment in the dosage. Under these conditions we now would abandon the use of OMPA and would revert to treatment with neostigmine alone, regardless of how unsatisfactory its effects might be. We believe, too, that some safe upper limit of dosage should be set and never exceeded under any circumstances. Our patients who died from intoxication were receiving prescribed doses of 40, 50, and 56 mg. a day, respectively, at the time of death. Among those who are doing well, one takes as little as 9 mg. a day; the largest dose is 28 mg. On the basis of our experience and that reported by others, we have arbitrarily set the dose of 30 mg. a day as the upper limit. We try, however, to administer the smallest possible dose that will result in reasonably good therapeutic effect.

CLINICAL NOTES

HEMORRHAGIC ENCEPHALOPATHY DURING ARSENIC THERAPY FOR ASTHMA

Louis E. Prickman, M.D.
and
Clark H. Millikan, M.D., Rochester, Minn.

A serious potential danger inherent in the use of potassium arsenite (Fowler's solution) in the treatment of asthma is illustrated in the following case.

REPORT OF A CASE

A 34-year-old man came to the Mayo Clinic on June 8, 1952, and was hospitalized at once, because he was in critical condition. The patient had had both pneumonia and asthma in 1941 while in the Army. Nonseasonal asthma had recurred each year, usually in association with respiratory infections. There was no family history of allergy; the patient had no other known allergic condition and had shown no allergy to drugs that had been administered for respiratory infections.

On April 18, 1952, the patient had begun to take a liquid that contained arsenic prescribed by a physician. He had followed the directions the physician provided to eliminate danger from the arsenic and had even written to the physician for advice when trouble developed. Three weeks before admission to the Mayo Clinic, however, the patient could not read or drive, because his vision had become blurred. He had been able to do some work on his farm until about that time and then had to stop work because of dyspnea, although he was not bedfast. About two weeks before admission, edema of the ankles and puffiness of the eyelids were noted. Increased visual changes (blurring and partial loss of vision) were noted about the same time. The patient's walk had been unsteady since about June 1.

On June 7, after eating a fair noon meal, he complained of pain in his neck, had difficulty in walking, had numbness of the feet, and said they "felt like clubs." He ate little that evening, did not feel well, and noticed twitching. He retired at 9:00 p.m., awakened about 10:00 p.m., and got out of bed but could not find his way around the house and was frankly disoriented. He gradually became worse and more restless until at 6:00 a.m. on June 8 he did not recognize his wife. He continued a restless muttering and was delirious during the day of June 8, until he was brought to the clinic and hospitalized. The physician who had prescribed the arsenic preparation practiced far from the patient's home. Before he came to the clinic, therefore, the patient had consulted his family physician, who had administered seven doses of dimercaprol (BAL) to counteract arsenic poisoning.

On admission to the hospital, the patient was stuporous, delirious, and irritable and resisted passive motions of the extremities. He had twitching of the arms and stiffness of the neck, and Babinski signs were elicited bilaterally. The pupils were contracted and did not react to light. The eyes were in the sleep position, from which they did not deviate. He made defense reactions with the right hand but not with the left. The right leg reacted well to a pin prick, but the left leg did not. The rectal temperature on admission was 101.2 F, the pulse rate was 122 beats per minute and regular, respirations were 30 per minute, and the blood pressure was 130/86 mm. Hg. Cyanosis was present, and the patient was sweating profusely. The lips were dry and crusted. The heart was not enlarged. Inspiratory and expiratory crepitant and wheezing rales and rhonchi were heard over the entire lung fields. No consolidation was noted in the lungs. The liver was not palpable. Pitting edema, grade 2+ (on a grading basis of 1 to 4), was present in the ankles. Pigmentation and keratoses were not noted on the hands or feet. Examination of the ocular fundus was relatively inconclusive, but gross choking of the disks could not be seen. The pressure of the cerebrospinal fluid was elevated to 480 mm. of water, and the fluid was slightly yellow. It contained 10 lymphocytes, 1 polymorphonuclear leukocyte, 2 undifferentiated cells, and 2,400 erythrocytes per cubic millimeter. Cerebrospinal fluid protein was 20 mg. per 100 cc. (corrected for erythrocytes to 17 mg. per 100 cc.). A tentative diagnosis of diffuse hemorrhagic encephalopathy due to arsenic was made, and dimercaprol was administered. The patient was given oxygen, fluids intravenously, with aminophylline, crystalline and procaine penicillin, and phenobarbital sodium.

On the morning of June 9 the patient was disoriented, singing, and responded at times by speaking, which he had not done on the night of admission. He made more purposeful movements of the right hand and was able to deviate his eyes slightly. Edema had almost disappeared from the right leg and foot, and edema in the left lower extremity had decreased. Urinalysis disclosed a specific gravity of 1.027, acid reaction, albumin 2+, no sugar, erythrocytes 2+, and an occasional pus cell. The urine contained 0.10 mg. of arsenic per liter. The hemoglobin concentration was 16.4 gm. per 100 cc. of blood, and there were 4,770,000 erythrocytes per cubic millimeter and 12,000 leukocytes per cubic millimeter, of which 13% were lymphocytes, 7.5% monocytes, and 79.5% neutrophils. The erythrocyte sedimentation rate (Westergren method) was 1 mm. per hour. The concentration of blood urea was 28 mg. per 100 cc., plasma chlorides 88.5 mEq. per liter, and plasma carbon dioxide 38.0 mEq. per liter. A roentgenogram of the thorax showed scattered areas of increased density suggestive of diffuse early pneumonitis in the midzone of the right lung.

On June 9, the patient was transferred to the neurological section of the hospital, where treatment with dimercaprol 2 cc., preceded by doses of ephedrine, was continued at eight hour intervals. Oxygen, phenobarbital sodium, and penicillin also were given. The course was stormy for approximately 10 days. The patient was placed in an oxygen tent, and particular attention was given to maintaining the electrolyte balance. Administration of dimercaprol was continued until June 23, during which time he received a total of 34 cc. Treatment with one million units of penicillin daily was continued until June 17, and during this period the highest daily temperature was 100.7 F.

Asthmatic paroxysms, on June 9, responded poorly to epinephrine given subcutaneously and aminophylline, 7.5 grains (approximately 0.5 gm.) given intravenously, so 10 mg. of corticotropin, administered intravenously, was added to the

From the Division of Medicine and the sections of neurology and psychiatry, Mayo Clinic.

fluids. Intravenous use of aminophylline, oral use of ephedrine, and subcutaneous use of epinephrine usually controlled later asthmatic paroxysms, but asthmatic rales and rhonchi were always present. By June 12, the patient was clearing secretions from his throat; he swallowed the secretions, and the chest was then almost clear. Use of the oxygen tent was discontinued on June 14. The indwelling catheter was removed on June 20.

The cerebrospinal fluid was examined again on June 10 and 12. On June 10, the pressure was 520 mm. of water. The fluid contained 2 lymphocytes, 12 polymorphonuclear leukocytes, 8,000 erythrocytes per cubic millimeter, 40 mg. of protein per 100 cc., 115 mg. of sugar per 100 cc., and 660 mg. of chlorides per 100 cc. Cultures were negative for microorganisms. On June 12, the initial pressure was 140 mm. of water. The values in the fluid were: 4 lymphocytes, 3,733 erythrocytes, 25 mg. of protein per 100 cc., 88 mg. of sugar per 100 cc., and 680 mg. of chlorides per 100 cc. Smears of the cerebrospinal fluid were negative for acid-fast bacilli, and cultures for tubercle bacilli were negative. A specimen of urine on June 11 was small but was estimated to contain 0.40 mg. of arsenic per liter, and a specimen on June 13 contained 0.05 mg. of arsenic per liter. An analysis of the medicine that the patient had been taking before his hospitalization (until about May 31) showed 5 gm. of arsenic per liter.

On June 14, the patient was still stuporous, answered "yes" and "no," and obeyed commands to expectorate. The left upper extremity was completely flaccid and did not respond to stimulation, nor did the left leg respond except for spontaneous movement. The Babinski sign was elicited on the right. He could not see well enough to count fingers, and his neck remained stiff.

Examination of the ocular fundus on June 14 was still inconclusive because of the patient's restlessness, but the disks were flat, and there was a large flame-shaped retinal hemorrhage of the superior temporal margin of the left disk and a deep retinal hemorrhage below the left disk (2 D. away from the disk). The right disk was flat, and the veins were large, especially the inferior temporal vein, but no evidence of hemorrhage or hypertensive changes could be seen.

By June 15, the patient was generally much improved, although he was completely disoriented. He could turn himself, drink out of a glass, and follow simple directions. By June 16, he recognized relatives and could see light but apparently did not see fingers. Examination of the eyes on June 17 revealed slight reaction of the right pupil to light; the left pupil was fixed. The hemorrhages in the left eye were smaller and apparently being absorbed. Four round spots indicating deep hemorrhages were noted in the right eye. A diagnosis of amaurosis and toxic retrobulbar neuritis was made. On June 20, the patient was eating well and was able to walk. He was still amaurotic but seemed to see light consistently in the right temporal field. Extensor toe signs were absent. Roentgenograms of the chest and skull on June 17 showed nothing abnormal. The leukocyte count on June 21 was 6,300. Urinalysis showed specific gravity of 1.017, acid reaction, a trace of albumin, no sugar, and only an occasional pus cell.

The patient continued to improve generally and was discharged on June 26. He had no dyspnea, felt well, was eating well, was able to walk, and was oriented, but seemed completely blind and had poor memory. He was emotionally labile and facetious. He was advised to return in two to three months for further observation, but he has not felt this necessary.

An etiological investigation of the asthmatic bronchitis was not carried out during hospitalization because of the patient's serious illness; however, the history and findings were consistent with those seen in intrinsic asthmatic bronchitis. He was advised to avoid respiratory irritants such as colds, dusts, smoke, fumes, sudden temperature changes, cold frosty air, and any situation that promotes coughing and to use symptomatic remedies such as iodides, epinephrine, and aminophylline if necessary.

On March 16, 1953, the patient's wife wrote that he was able to distinguish dark colors, such as red, blue, and purple, could name a few playing cards, and could distinguish large letters. He had frequent headaches, and his head felt "thick." Some sensation was returning to his left arm and hand, and he could carry a pail in his left hand. He was also able to walk well. His memory, except for the period from January to September, 1952, was good. His attitude was pleasant, and he behaved normally. He was unable to ride in a car, because it made his head ache and made him feel "jumbled" for two or three days.

COMMENT

In discussing treatment for asthma, Gay and Gay[1] stated: "There have been no known deaths attributed to the medication, but there have arisen occasional episodes of arsenical and iodide reactions which have been corrected without mishap." Our experience does not agree with this statement. Sollmann[2] wrote that "Inorganic arsenic is capricious, unpredictable, and uncontrollable both as to good and harm, but the harm is more certain and generally more frequent than the good." Arsenic, particularly in the trivalent form, is a potentially dangerous drug and may cause changes in the skin, liver, peripheral nerves, and central nervous system. Our patient probably had some damage to certain peripheral nerves, but the most important toxic effects were in the brain. Hemorrhagic encephalopathy due to ingestion of arsenic is acute, and, unless treatment is started immediately, death may ocur in 24 to 72 hours after the onset of symptoms. This patient was able to eat dinner the evening of June 7 and by 6:00 a. m. of the next day was delirious. Stupor, coma, many types of abnormal movement (in this instance restlessness and twitching of muscles), convulsions, and almost any neurological deficiency may be associated with the disorder. Damage to the nervous system occurs quickly, is severe (multiple hemorrhages in the brain or spinal cord or both), and, although improvement can occur, may leave serious residual defects of function. When such symptoms appear in a person who has been taking arsenic therapeutically or who possibly has been exposed to the ingestion of arsenic, the diagnosis of arsenical encephalopathy must be considered and treatment with dimercaprol started immediately.

Dimercaprol is the compound 2,3-dimercaptopropanol. In arsenic poisoning, competition develops in the body between sulfhydryl groups of tissue enzyme systems and the sulfhydryl groups of dimercaprol. The sulfhydryl groups in the drug combine with the arsenic, permitting those of the tissue enzyme systems to return to normal action. The arsenic combined with the sulfhydryl groups of dimercaprol is excreted from the body. As implied, sulfhydryl groups already combined with arsenic can be made to release the metal when large doses of dimercaprol are given, and the toxic effects of arsenic on cells may be counteracted in this manner. Dimercaprol can be administered intramuscularly every four to six hours to patients who are acutely ill. Each vial contains 4 cc. of a 10% solution. Each cubic centimeter, therefore, equals 100 mg. of the drug. A dose of 2 to 2.5 mg. per kilogram of body weight is used. Toxic effects of dimercaprol are paresthesia, sweating, pain in the limbs and jaws, excessive lacrimation, blepharospasm, excessive salivation, vomiting, restlessness, and weakness.

---

[1] Gay, F. S., and Gay, E. D.: The Gay Treatment of Asthma, Mississippi Doctor 29: 142-143 (Nov.) 1951.

[2] Sollmann, T. H.: A Manual of Pharmacology and Its Applications to Therapeutics and Toxicology, ed. 7, Philadelphia, W. B. Saunders Company, 1948, p. 1132.

When dimercaprol is administered as directed, the toxic effects are not ordinarily dangerous; therefore, if a diagnosis of arsenic intoxication is suspected but has not been completely established, immediate treatment with dimercaprol is indicated. The serious action of arsenic on the nervous system may occur so quickly that the patient may die before laboratory confirmation of the diagnosis is possible. The physician who administered seven injections of dimercaprol before the patient's arrival at the Mayo Clinic is to be commended. This prompt and adequate administration of dimercaprol may well have saved the patient's life.

Even though arsenic is eliminated from the body the damage produced may be permanent. As with any severe vascular lesion or lesions of the brain, a definite defect in neurological function may persist, as in this case. Physical therapy and measures aimed at training the patient to perform certain ordinary actions constitute treatment in the months after the acute phase of the illness is past.

SUMMARY

The treatment of asthma with potassium arsenite (Fowler's solution) is potentially hazardous. Hemorrhagic encephalopathy developed rapidly in a man who was given potassium arsenite for treatment of asthma. This case illustrates only one of several hazards incident to arsenic therapy for asthma; others have been reported in THE JOURNAL [3] and elsewhere.[4] The self-administration of arsenic compounds without the supervision of a physician is strongly condemned.

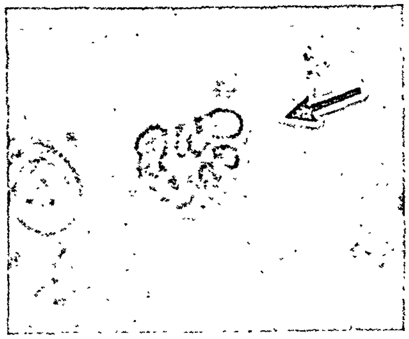
STAIN FOR LIPID BODIES IN URINARY SEDIMENT

Alvin E. Parrish, M.D.
and
Louis K. Alpert, M.D., Washington, D. C.

Staining urinary sediment to facilitate the identification of various constituents has not been widely utilized until recently.[1] Sudan III has long been used, to a limited extent, for the identification of fat in the urine.[2] Since the presence of fat in casts or cells in the urinary sediment is frequently associated with renal tubular degeneration in diseases such as glomerulonephritis, intercapillary glomerulosclerosis, renal amyloidosis, lupus erythematosus, and "lipoid" nephrosis, the recognition of fat in the urinary sediment is helpful in making a correct diagnosis. Usually it is observed through a Nicol prism or other polarizing mechanism in the lens system of a microscope. By using Sudan III, we have developed a simple technique for the demonstration of fat globules in urinary sediment.

METHOD

Fresh urine specimens are centrifuged and the supernatant fluid decanted, leaving approximately 0.2 to 0.3 cc. in the tube. Two to three drops of a saturated solution of Sudan III dissolved in 70% alcohol are mixed with the sediment. A drop of this mixture is placed on a microscope slide and covered with a cover glass. Fifteen to 60 minutes later, this specimen is examined under an oil immersion lens. Fatty material in casts and cells appears as salmon-red globules (see figure). A blue light source enhances the color. These globules stand out in contrast to the other material that is not stained.



Lipid globules in renal tubular cell stained with Sudan III.

This method has been used in the examination of the urine of 24 patients with renal disease associated with the presence of lipid in the urinary sediment and has been compared with the usual procedure for observing doubly refractile bodies with the use of polarized light. In all instances in which doubly refractile lipid was found, staining with Sudan III was also observed. Usually a greater quantity of Sudan III staining material was noted than birefringent bodies.

SUMMARY

A simple procedure for the demonstration of lipid bodies in the urinary sediment is described.

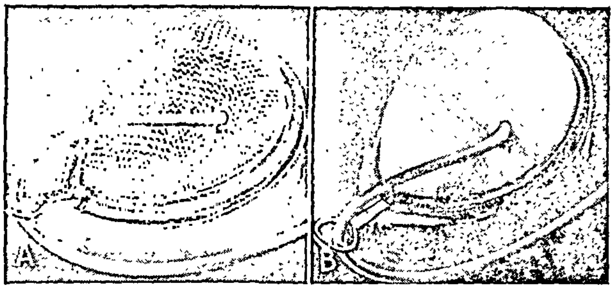
Tumors in Region of Optic Chiasm.—Early in their development, tumors of the region of the optic chiasm impair vision; as they increase in size they lead to blindness. Preservation of vision is the chief aim of treatment, whether it be by surgical intervention or irradiation, and the effectiveness of treatment is judged on the basis of visual fields and acuity. Consequently, ophthalmologists must be on the alert for these tumors in every case of visual loss not explained by ophthalmoscopic examination.—C. W. Rucker, M.D., Tumors of the Region of the Optic Chiasm, *Digest of Ophthalmology and Otolaryngology*, July, 1953.

MODIFIED ETHER MASK FOR SIMULTANEOUS ADMINISTRATION OF ETHER, AIR, AND OXYGEN

Bernard Stodsky, M.D., Chicago

Significant reduction in oxygen saturation of arterial blood by the application of an ether mask to the patient's face and further reduction by the application of ether to the mask have been demonstrated by Faulconer and Latterell.[1] They showed that addition of 500 cc. of oxygen per minute to the ether and air mixture under the mask would restore the arterial oxygen saturation to normal levels and suggested that this procedure be practiced routinely in semiopen ether-air administration. Acting on this suggestion, I devised a modification of the standard Yankauer ether mask that provides a simple, dependable, and unencumbered method for addition of oxygen.

As shown in the figure, shower curtain eyelets, or grommets (Dot eyelets no. 659), are riveted in place through the screening on the right and left sides of the mask (to accommodate right-handed and left-handed anesthetists). The eyelet of this size accommodates a no. 14F red rubber urethral catheter. Four to six additional holes are punched in the end of the catheter, and it is "strung" through the mask, as shown in the figure. It is important that the catheter be threaded through the ring of the retaining spring before it is passed through the gauze mesh and eyelet, since this provides strain relief and prevents the catheter's slipping out of the mask. A pencil point is twirled through the gauze and into the eyelet to separate the gauze mesh for passage of the catheter. The catheter is connected to a metered source of oxygen, and, with the flow set at a starting rate of 500 cc. per minute, the mask is applied to the face. Induction is smooth and pleasant, and cyanosis due to reduced arterial oxygen saturation is eliminated.



A, modified ether mask, showing position of eyelet and rubber catheter; *B*, the mask ready for use.

SUMMARY

A simple modification of the standard Yankauer ether mask that makes possible efficient, unencumbered, simultaneous administration of ether, air, and oxygen by the semiopen method is described.

8827 Dorchester.

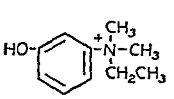
COUNCIL ON PHARMACY AND CHEMISTRY

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

R. T. Stormont, M.D., *Secretary.*

Edrophonium Chloride.—Tensilon Chloride (Hoffmann-La-Roche).—$C_{10}H_{16}ClNO$.—M.W. 201.69.—Dimethylethyl(3-hydroxyphenyl)ammonium chloride.—The structural formula of edrophonium chloride may be represented as follows:



Actions and Uses.—Edrophonium Chloride is a competitive antagonist of skeletal muscle relaxants such as tubocurarine, similar-acting curare derivatives, and gallamine triethiodide, which produce their effect by interference with the ability of acetylcholine to depolarize the endplate at the myoneural junction. It displaces such curare-like drugs from their attachment to the muscle cell, permitting resumption of the normal transmission of neuromuscular impulses. Therefore, the drug is useful as an antidote against the peripheral action of curariform agents, either to terminate their therapeutic relaxant effect when it is no longer required, or to reverse respiratory muscle paralysis caused by overdosage. Edrophonium chloride does not combat circulatory collapse which is sometimes associated with respiratory depression produced by a central effect of curariform drugs. With extremely large doses, the action of edrophonium becomes curariform and capable of potentiating rather than antagonizing the peripheral paralytic effect of curare. In the presence of apnea, the response to the antidotal action of edrophonium cannot be observed, and there is no clinical guide to effective dosage. For these reasons, the drug should be employed only as a supplement to artificial respiration and oxygen therapy in the treatment of respiratory depression caused by curare overdosage; but, in order to avoid overdosage, edrophonium should be used for this purpose only when some definite sign of voluntary respiration, such as excursion of the diaphragm, can be observed. Under no circumstances should the drug be employed without observing proper precautions in the administration and dosage of curariform agents.

Edrophonium exhibits the parasympathomimetic actions characteristic of neostigmine to some degree, but in the antidotal dosage range, it is slightly shorter-acting and produces a lower incidence of side-effects. Like the anticholinesterases such as neostigmine, edrophonium prolongs rather than antagonizes the skeletal muscle relaxant action of succinylcholine chloride and should not be used as an antidote for that drug. Increased salivation and bronchiolar spasm have been occasionally reported in patients with asthma, bradycardia, and cardiac dysrhythmia in conjunction with electrocardiographic changes in older patients. The drug, therefore, should be employed with caution in bronchial asthma or cardiac disease. Atropine usually relieves such side-effects.

Edrophonium chloride is also useful as a diagnostic agent to differentiate between the presence or absence of myasthenia gravis, and for the emergency treatment of myasthenic crises. Its action is too short for maintenance therapy of that disease. Because of its shorter action, edrophonium has the advantage over neostigmine as a diagnostic agent of permitting repeated tests on the same patient several times in an afternoon. The diagnostic use of edrophonium is based upon its ability to produce increased muscle strength without fasciculations when administered to patients with myasthenia gravis. In nonmyasthenic patients the drug produces fasciculations but no increase in strength.

Dosage.—As an antidote for curariform drugs, edrophonium chloride is administered by intravenous injection in doses of 10 mg. (1 cc. of a solution containing 10 mg. per cubic centimeter). Smaller doses of 5 mg. each may be adequate for termination of curarization following electroshock therapy. When given to counteract curare overdosage, the effect of each dose on the respiration should be carefully observed before it is repeated and artificial ventilation should always be employed. The maximal dose for any one patient should be 30 mg. (plus or minus 10 mg.). Because the action of edrophonium is brief, it should not be given prior to, or as a prophylactic against, the administration of curariform agents. It should be given only at the time its antidotal effect is needed.

As a diagnostic agent in suspected cases of myasthenia gravis, a 10 mg. dose of the drug is injected intravenously. In persons having that disease, increase in muscle strength is observed with maximum improvement occurring within 30 seconds to 5 minutes following injection. In myasthenic crises the drug should be administered by continuous intravenous drip only for the duration of the emergency.

Tests and Standards.—

Physical Properties: Edrophonium chloride is a white, odorless, crystalline powder, m.p. 163-169° (with decomposition). It is very soluble in water, freely soluble in alcohol, and practically insoluble in ether. The pH of a 1% solution is 4.0-5.0

Identity Tests: Dissolve about 50 mg. of edrophonium chloride in 10 ml. of water, and add 2 drops of nitric acid and 1 ml. of silver nitrate T.S.: a white precipitate forms, which is insoluble in diluted nitric acid, but soluble in diluted ammonia solution *(presence of chloride).*

Dissolve about 50 mg. of edrophonium chloride in 5 ml. of water and add about 5 ml. of a saturated solution of picric acid. Allow the reaction mixture to stand for 10 min., filter, wash the precipitate with water, and dry in a vacuum desiccator *(Caution! May be explosive. Use safety glass shield.):* the yellow picrate melts at 161-163°.

A 0.0025% solution, prepared as described in the spectrophotometric assay for edrophonium chloride, exhibits ultraviolet absorption maxima at about 217 mμ [specific absorbancy, E(1%,1 cm.), about 291] and 273 mμ [specific absorbancy, E(1%,1 cm.), about 107], and a minimum at about 240 mμ. The ratio between the optical densities at 217 and 273 mμ is 2.6-2.8.

Purity Tests: Dry about 1 gm. of edrophonium chloride, accurately weighed, at 105° for 4 hours: the loss in weight does not exceed 0.5%.

Char about 0.5 gm. of edrophonium chloride, accurately weighed, cool the residue, add 1 ml. of sulfuric acid, heat cautiously until the evolution of sulfur trioxide ceases, ignite, cool, and weigh: the residue does not exceed 0.5%.

Assay: (Edrophonium Chloride) Prepare a 0.0025% solution of edrophonium chloride as follows. Transfer to a 100 ml. volumetric flask about 0.25 gm. of edrophonium chloride, accurately weighed, fill to the mark with water, and mix. Transfer to a second 100 ml. volumetric flask 10 ml. of this solution, fill to the mark with water, and mix. Transfer to a third 100 ml. volumetric flask 10 ml. of this last solution, fill to the mark with water, and mix. Spectrophotometrically determine the absorbancy in a 1 cm. quartz cell at 273 mμ, using water as a blank. The concentration of edrophonium chloride in the solution in mg./ml. = absorbancy ÷ 10.7. The amount of edrophonium chloride is not less than 95.0 nor more than 105.0%.

Prepare 0.1 *N* perchloric acid as follows. Add 14.5 gm. of 70-72% perchloric acid to 960 ml. of glacial acetic acid contained in a 1000 ml. volumetric flask and mix well. With cooling and constant stirring, slowly add 24.2 gm. of acetic anhydride. Allow the solution to stand for 24 hours. Standardize the acid at 25° against potassium acid phthalate in glacial acetic acid (1:40), using 5 drops of 1% crystal violet in glacial acetic acid as an indicator and titrating to a blue-green end point. Transfer to a 250 ml. Erlenmeyer flask about 0.25 gm. of dry edrophonium chloride, accurately weighed, add 40 ml. of glacial acetic acid, and, if necessary, heat gently on a steam bath to complete solution. Cool and add 10 ml. of a 1% solution of mercuric acetate in glacial acetic acid. Titrate the solution with 0.1 *N* perchloric acid in glacial acetic acid, using as an indicator 5 drops of a 1% solution of crystal violet in glacial acetic acid. Each milliliter of 0.1 *N* acid is equivalent to 0.02017 gm. of edrophonium chloride. The amount of edrophonium chloride is not less than 98.5 nor more than 101.5%.

Dosage Forms of Edrophonium Chloride

SOLUTION. *Identity Tests:* To an amount of solution containing the equivalent of about 50 mg. of edrophonium chloride, add 5 ml. of a saturated solution of picric acid. Allow the mixture to stand for about 10 min., filter, and wash the precipitate with water and dry in a vacuum desiccator *(Caution! May be explosive. Use safety glass shield.):* the yellow picrate melts at 161-163°.

Assay: (Edrophonium Chloride) Transfer to a beaker an amount of solution, accurately measured, equivalent to 25 mg. of edrophonium chloride and evaporate the solution to dryness on a steam bath. Add about 5 ml. of water and again evaporate to dryness. Repeat the process with two additional 5 ml. portions of water. Dissolve the residue in water, quantitatively transfer the solution to a 100 ml. volumetric flask, fill to the mark with water, and mix. Transfer to a second 100 ml. volumetric flask 10 ml. of this solution, fill to the mark with water, and mix. Spectrophotometrically determine the absorbancy in a 1 cm. quartz cell at 273 mμ, using water as a blank. The concentration of edrophonium chloride in the solution in mg./ml. = absorbancy ÷ 10.7. The amount of edrophonium chloride is not less than 93.0 nor more than 107.0% of the labeled amount.

Hoffmann-LaRoche, Inc., Nutley, N. J.

Solution Tensilon Chloride: 10 cc. vials. A solution containing 10 mg. of edrophonium chloride in each cubic centimeter. Preserved with 0.2% sodium sulfite and 0.5% phenol. U. S. trademark 570,951.

Thiopental Sodium-U.S.P. (See New and Nonofficial Remedies 1953, p. 261).

Abbott Laboratories, North Chicago, Ill.

Pentothal Sodium (Rectal): 1.5 gm. vials. Buffered with 90 mg. of anhydrous sodium carbonate.

COUNCIL ON PHYSICAL MEDICINE AND REHABILITATION

APPARATUS ACCEPTED

The following additional products have been accepted as conforming to the rules of the Council on Physical Medicine and Rehabilitation of the American Medical Association for inclusion in Apparatus Accepted. A copy of the rules on which the Council bases its action will be sent on application.

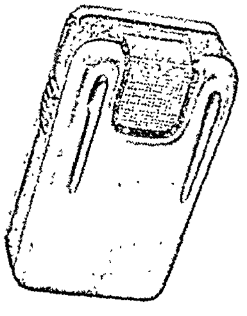
RALPH E. DE FOREST, M.D., *Secretary.*

Audivox Hearing Aid, Model 70

Audivox, Inc., 123 Worcester St., Boston 18.

The Audivox Hearing Aid, Model 70, is a three tube instrument requiring a 1.5 volt mercury type A-battery and a 15 volt B-battery. With batteries, receiver, and receiver cord the total weight ranges from 128.2 to 132.3 gm., depending on the type of receiver. Five different receivers are supplied. The body of the instrument measures 75 by 45 by 22 mm.

Evidence of satisfactory construction and performance was obtained by the Council.



Audivox Hearing Aid, Model 70

Schroeter Whirlpool Carriage, Model B

C. M. Sorenson Co., Inc., 50-19 47th Ave., Woodside, Long Island, N. Y.

The Schroeter Whirlpool Carriage is a device for agitating the water in a bathtub or basin. It can be moved alongside the tub, the top of the apparatus then raised, rotated through an angle of 90 degrees, and lowered over the side of the tub into the water.

This apparatus is a successor to the Schroeter Whirlpool Carriage, Model A, accepted by the Council in 1948, when it was manufactured by Whirlpool Carriage, Inc., of Brooklyn. Model B is lighter, weighing only 27 kg. (50 lb.) and is high enough to swing over the edge of a tub 45 cm. (18 in.) above the floor. The motor requires either alternating or direct current at 110 volts and draws 400 watts.

CHLOROPHYLL AS A DEODORANT

For a number of years water-soluble derivatives of chlorophyll have been used for the purpose of eliminating unpleasant odors from wounds[1] or from the air. More recently a number of investigators[2] have reported that chlorophyll derivatives taken orally are capable of reducing unpleasant body odors. On the basis of these and other reports enterprising promoters have sold tremendous quantities of chlorophyll derivatives to the public in tablets, mouth washes, tooth pastes, and other vehicles. More recently several authors have questioned the whole concept of chlorophyll deodorization. Brocklehurst[3] of the University of Glasgow has tested the effect of four water-soluble derivatives of chlorophyll on a variety of odors in the laboratory and in man and has found no evidence that these preparations exerted any significant deodorizing action under any of the conditions of his experiments. Two of the derivatives used were proprietary preparations sold for oral use and for room deodorization respectively.

In his first experiments Brocklehurst used only objective criteria for the evaluation of the action of the chlorophyll derivatives so as to eliminate the well-known effects of suggestion on the sense of smell. Constant quantities of methylmercaptan gas (one of the substances contributing to the odor of the gas normally present in the lower bowel) were passed through filter paper screens soaked with chlorophyll derivatives, or through solutions of these derivatives, and the amount of unaltered methylmercaptan emerging was measured chemically. He found that the water-soluble chlorophyll derivatives removed or altered no more methylmercaptan than did plain water and in one experiment removed less.

In subsequent experiments the sense of smell was used to evaluate the effect of chlorophyll derivatives on various odors, but attempts were constantly made to eliminate the element of suggestibility. Small quantities of methylmercaptan, ether, or syrup of garlic were placed under bell jars in which were suspended filter papers saturated with various soluble chlorophyll derivatives. The characteristic odor of each of the three substances was still present in the jars 12 to 47 hours later in 21 or 22 tests. In the 22nd test the odor of the chlorophyll derivative was so strong that it was believed to have masked the mercaptan odor. Similarly, mixtures of chlorophyll derivatives and syrup of garlic retained their unpleasant odor for 30 days, and a mixture of onion slices and chlorophyll derivatives developed such an offensive odor after 24 hours that the experiment had to be abandoned.

Brocklehurst next tested chlorophyll derivatives clinically in a patient who was incontinent of urine. This patient was given proprietary "chlorophyll" tablets or sodium copper chlorophyllin solution in three-day courses alternating with three-day periods without chlorophyll derivatives. The days on which the different courses were given were not known to the observer. The characteristic and unpleasant odor of urine was present throughout the test period. In two other subjects the odor imparted to the urine by asparagus was not eliminated after the ingestion of 25 times the recommended daily doses of water-soluble chlorophyll derivatives. This observation was confirmed by Alstead[4] in 10 additional patients. Brocklehurst also noted that the ingestion of 800 mg. of chlorophyll substance daily for a week did not cause the smell of feces or axillary perspiration to disappear.

Other students of the problem have also taken issue with the claims made for chlorophyll and its derivatives. E. R. Weaver[5] of the National Bureau of Standards comments: "We have no reason whatever to believe that chlorophyll ever has anything to do with deodorization." A. H. Corwin[6] of the Johns Hopkins University department of chemistry, states that the whole concept of chlorophyll as a bacteriostatic and deodorizing agent is founded on a misconception. While it has been claimed that chlorophyll breaks down carbon dioxide and sets free oxygen that inhibits the action of odor-producing anaerobic bacteria, Corwin points out that "chlorophyll has no such property. Only intact chloroplasts have the power to fix carbon dioxide and then only in the presence of light. . . . Successful photosynthesis requires not only unaltered chlorophyll, but also unaltered chloroplasts in much more precise organization than is possible in solution." Furthermore, the commercial water-soluble preparations do not contain chlorophyll, which is very insoluble, but rather the products of alkaline hydrolysis of chlorophyll (chlorophyllins), in which subsequently the central magnesium atom has been replaced by copper or nickel. The final products are believed to be copper or nickel pheophytins rather than chlorophyllins.[7] In addition, according to Corwin, the standard commercial preparations contain a number of impurities. Several observers have suggested that the activity of chlorophyll derivatives used as space deodorants may be due, in part at least, to the presence in such preparations of some fragrant substance such as pine oil that can mask less pleasant odors, or to the presence of a small amount of formaldehyde, which is capable of paralyzing olfactory nerve endings so that unpleasant odors can no longer be detected. One of the proprietary chlorophyll derivatives tested by Brocklehurst contained a perfume that fairly effectively masked the odor of methylmercaptan in solution, but only when the mixture was shaken to permit the odor of the perfume to emerge.

[7] Thimann, K. V.: Personal communication to the author.

The masking mechanism would not, of course, explain the reputed action of ingested chlorophyll in reducing body odors. So many observers have reported such effects that they cannot be dismissed lightly, but it must be remembered that the sense of smell is one of the least reliable for purposes of quantitative analysis of stimuli because of the phenomenon of rapid fatigue and the potent influence of suggestion. Brocklehurst attempted to minimize such variables by recording only the presence or absence of odor without trying to measure variations in intensity. This may account in part for the differences between his conclusions and those of other workers. It has also been suggested that variations in the composition of different commercial preparations may account for such discrepancies. It seems apparent that no final conclusion can be reached about the deodorizing effects of chlorophyll derivatives until the composition of the various preparations is more exactly delineated, the fate of ingested chlorophylls in the body is determined, and more objective testing has been done.

CAT SCRATCH DISEASE AND PARINAUD'S OCULOGLANDULAR SYNDROME

A new clinical entity characterized by subacute lymphadenitis, in which the lesion frequently suppurated and healed without a scar was reported in 1950 by Debré and his co-workers.[1] The patients often had a history of being scratched by a cat. This clinical entity was recognized in the United States by Foshay of Cincinnati about 20 years before the French workers described it. In the course of his studies on tularemia Foshay had recognized this particular entity and had prepared an antigen from the pus of an involved lymph node that gave positive reactions on intradermal injections. Foshay did not report these observations; however, he had given Debré a supply of his antigen. Recently, Mollaret and his collaborators [2] announced the discovery of the particular virus causing the disease.

In 1889 Parinaud presented before the Ophthalmologic Society of Paris three cases of conjunctivitis acquired from slaughterhouse animals and accompanied by pronounced enlargement of regional lymph nodes. Inoculation of the material obtained from these nodes into guinea pigs gave negative results. In a recent review Allen [3] defines Parinaud's oculoglandular syndrome as a conjunctivitis with a definite clinical picture and a variety of causative agents, such as Leptothrix, Mycobacterium tuberculosis, Pasteurella tularensis, and virus. Verhoeff believed that Leptothrix was the etiological agent in all cases. Pesmé and Marchand [4] reported a case of conjunctivitis with swelling of the preauricular lymph nodes and fever in a 6-year-old boy who had been bitten and scratched by a cat. An intradermal test with an antigen of cat scratch fever obtained from the pus of lymph nodes of a patient from Debré's laboratory gave a positive reaction.

Henry [5] reported eight cases of oculoglandular conjunctivitis due to Leptothrix in seven of which the patients gave a history of exposure to cats. She believed the source of infection was probably from cats and that this could explain the common occurrence of this entity in children. Lavergne [6] and his associates reported about the same time a case of Parinaud's syndrome in which the diagnostic tests for tularemia, lymphogranuloma venereum, and syphilis were negative, but the intradermal skin test with cat scratch antigen gave a positive reaction. Cassady and Culbertson report [7] in a recent issue of the *A. M. A. Archives of Ophthalmology* four cases of Parinaud's oculoglandular syndrome. All of the diagnostic tests in their cases were negative. When an antigen of cat scratch fever became available, the patients were reexamined and all of them gave a strongly positive skin reaction against this antigen. These authors point out that, although Leptothrix has been held responsible for the disease oftener than any other organism, this organism is frequently found as a saprophyte, unassociated with disease of any kind. Tularemia and yeast-like organisms have only in rare instances been proved causative. The fact that Parinaud's conjunctivitis is apparently not transmitted by man makes the likelihood of an animal vector seem reasonable. The clinical features, particularly systemic reaction occurring in Parinaud's oculoglandular syndrome, are quite similar to those occurring in the cutaneous glandular form of cat scratch fever. The syndrome, they stress, seems to vary from the latter entity only in its portal of entry and in the location of its primary complex.

It appears, therefore, quite likely that Parinaud's oculoglandular syndrome is a manifestation of cat scratch fever, which differs in that the conjunctiva is the site of primary infection, the initial lesion being one of conjunctivitis with granulation, followed by regional lymphadenitis.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

A truce has been signed in Korea. I join with other Americans in praying that a real and permanent peace can be achieved. While those entrusted with such political matters debate the nature of the peace, our Korean veterans will be coming home to resume their civilian pursuits. A grateful nation will pay tribute to all alike, which is as it should be. Few men in war can choose their own assignments.

Unfortunately the laudable desire to "do right by our boys" has been preempted by certain organizational leaders, whose motives are sometimes difficult to discern. They are the persons who would make of war veterans a class of citizens apart from the rest of the nation. They would make veterans dependent on the government for their every basic need. They forget that the majority of veterans are self-sufficient, intelligent, tax-paying citizens who do not wish to be relegated to second-class citizenship!

In a democratic nation we cannot have two types of citizenship. To serve one's country is a duty and an honor and the only claim that any of us has as basic right is that principle for which we fought—individual freedom and dignity. Those of us who took active part in our nation's wars did not follow the colors to become wards of the government.

The campaign to perpetuate free medical care in government hospitals for veterans with non-service-connected disabilities is a prime example of misguided thinking. Certainly no one can deny that a man who has served his country in uniform and has become physically handicapped as a result of such service is entitled to special consideration. The American Medical Association is in complete accord with the overwhelming sentiment of the American people in this regard. And the A. M. A. feels strongly that the federal government should provide the finest medical care obtainable for such veterans. In fact, it is largely through the efforts of the medical profession that the quality of veterans' medical care has been greatly improved over the years.

But the A.M.A. is unalterably opposed to a program of veterans' medical care in which more than 500 million dollars was expended last year alone, and of which amount only 178 million dollars went for the care of service-connected disabilities. In the face of a veteran population that is approximately 20 million, and that is increasing at the rate of 1 million annually, there is much pressure being brought on members of Congress to keep alive a medical care program for veterans with non-service-connected disabilities. Strong efforts are being made to encourage the building of more Veterans Administration hospital facilities. Yet in his annual report last year the director of the Veterans Administration stated that 7,274 otherwise available hospital beds were closed because of lack of professional personnel. Furthermore, a management survey of VA activities showed that 51,000 beds would serve all future needs of veterans with service-connected disabilities. In 1952, the VA hospital network had a total of 116,986 beds. During the past few years, with upwards of 500,000 veterans making use of the available VA hospital facilities each year, more than 80% of the patients who were treated had ailments that did not result directly from, nor were aggravated by, their military service.

Under the Hill-Burton program, enacted in 1946, a total of $542,500,000 has been expended by the federal government in encouraging local communities in each state to meet their own hospital needs. Communities that have built new hospitals under the Hill-Burton program have maintained them without further cost to the federal government. Of utmost importance is the fact that this program has been working effectively to improve the availability of hospital care for the entire population, including veterans. On the other hand, the Veterans Administration system, which is designed to provide care for a limited segment of the population, has received from Congress appropriations of many millions of dollars since about 1945 to add more hospital beds for veterans.

This duplication of effort on the part of the federal government is one of the basic reasons why the American Medical Association opposes the further expansion of the hospital facilities of the Veterans Administration and the perpetuation of medical care at federal expense for veterans who have non-service-connected disabilities.

Veterans Administration hospital staffs are doing a splendid job in caring for the patients in their charge. The American Medical Association believes, however, that the medical care of veterans with service-connected disabilities can be further improved if the care of most ex-servicemen with non-service-connected disabilities is made the responsibility of their respective community hospitals.

EDWARD J. MCCORMICK, M.D., Toledo, *Ohio*

ORGANIZATION SECTION

FEDERAL MEDICAL LEGISLATION

Taft Cancer Research Scholarships

Senator Magnuson (D., Wash.) proposes in S. 2571 to establish 10 yearly scholarships in cancer research, to be known as the Robert A. Taft Memorial Scholarships. These would be awarded by a committee of six, consisting of two members appointed by the Damon Runyon Fund, two by the National Cancer Society, and two by the National Cancer Institute of the Public Health Service. National Science Foundation funds would be used to finance the scholarships; provision would be made for setting aside $100,000 a year for this purpose. The bill was introduced and ordered to lie on the table so that it could be brought up on the Senate floor next January without being referred to a committee.

Income Tax Deductions

Senator Johnson (D., Colo.) proposes in S. 2495 to allow deductions not to exceed $150 for medical care including "court costs, attorneys' fees, and other necessary costs and fees incidental to legal proceedings for the adoption . . . of a child" for income tax purposes. This measure was referred to the Finance Committee.

Veterans Compensation for Loss of Lung

Senator Dirksen (R., Ill.) would amend the veterans regulations by S. 2576 to "provide additional compensation for the loss or loss of use of a lung as a result of service-incurred disability in time of war." This measure was referred to the Finance Committee.

Federal Aid to State or Territorial Homes

Congressman Curtis (R., Mass.) has introduced a bill, H.R. 6659, which would "increase the amount of Federal aid to State or Territorial homes for the support of disabled soldiers and sailors of the United States" from $500 to $750 per year. This bill was referred to the Armed Services Committee.

Extension of Social Security

Congressman Kean (R., N. J.) has introduced a bill, H.R. 6846, which would broadly revise and extend Old-Age and Survivors Insurance to 10,500,000 more persons, including physicians. This measure is identical with H.R. 6812 (Reed), previously reported. Both bills were referred to the Ways and Means Committee.

Social Security for All Citizens

Congressman Mack (R., Wash.) proposes in H.R. 6796 to amend the Social Security Act "to permit all citizens of the United States to receive at least minimum old-age and survivors insurance benefits, and, for the purpose of computing the primary insurance amount of an individual, such individual shall be deemed to have an average monthly wage of at least $100." There are also other changes increasing benefits in this measure. The bill was referred to the Ways and Means Committee.

Lower Retirement Age for Social Security Benefits

Congressman King (D., Calif.) proposes in H.R. 6666 to reduce from 65 to 60 the age at which retirement benefits would be payable. This bill was referred to the Ways and Means Committee.

Earnings Allowed Social Security Beneficiaries

Congressman Friedel (D., Md.) proposes in H.R. 6663 to increase from $75 to $100 per month the amount of income from wages or self-employment a beneficiary of social security may receive without losing his social security pension. The same proposal was made by Congressman Kean (R., N. J.) in H.R. 3608. This measure was referred to the Ways and Means Committee.

Financing Investigation of Tax-Exempt Foundations

Congressman Reece (R., Tenn.) in H. res. 373 provides $50,000 for the House Select Committee to Investigate Tax-Exempt Foundations. The measure was referred to the House Administration Committee, reported back to the House, and passed on August 1.

Vocational Rehabilitation for the Blind

Congressman Wainwright (R., N. Y.) proposes in H.R. 6657 to amend the Vocational Rehabilitation Act to require that all vending stands on federal property be operated by licensed blind persons if they are available, unless the site is certified by the state as unsuitable for operation by a blind person. A state agency must be designated to license blind persons to operate vending stands, and such agency must cooperate with the U. S. Department of Health, Education, and Welfare. The bill would subsidize blind vendors, including the purchase of initial stock, and would provide for loans to disabled individuals for "tools, equipment, initial stocks and supplies, including livestock, and capital advances." The measure was referred to the Education and Labor Committee.

Income Tax Deductions

The personal income tax exemption of the taxpayer "including the exemption for a spouse, the exemption for a dependent, and the additional exemption for old age or blindness" would be increased from $600 to $1,000 by a proposal of Congressman Holtzman (D., N. Y.) in H.R. 6511. This measure was referred to the Ways and Means Committee.

Income Tax Deductions for Annuities

Congressman Holtzman (D., N. Y.) has introduced a measure, H.R. 6509, which would exclude from taxable income "all amounts up to $2,500 per annum, received as a retirement annuity or pension" provided by governmental or private employer and any annuity purchased by the taxpayer himself. In the latter case, however, the tax exemption would apply only to the money actually paid into the fund by the taxpayer, and not to the fund's interest or earnings. This measure was referred to the Ways and Means Committee.

Amendment to Reorganization Act

Under the reorganization act of 1949, a reorganization plan must be accepted or rejected as a whole. Congressman Dodd (D., Conn.) in H.R. 6535 would amend this act to allow either house of Congress by a majority vote within the 60-day period to disapprove or eliminate one or more provisions of a presidential reorganization plan. This measure was referred to the Government Operations Committee.

A. M. A. POSTCONVENTION TRIP TO HAWAII

The American Medical Association has arranged for a postconvention trip to the Hawaiian Islands for physicians and their wives following the annual A. M. A. convention in San Francisco next June 21-25. The trip is being handled by Mr. W. M. Moloney, general agent for the Chicago, Burlington & Quincy Railroad, with offices in the Banker's Building, 105 West Adams Street, Chicago. Information and reservation blanks can be obtained from him.

The Hawaiian Holiday Trip starts when the convention ends. The A. M. A. party will leave San Francisco aboard either Pan American Airways Strato Clippers or United Air Lines Stratocruisers at 11:45 on the night of Friday, June 25. Both Pan American and United have offered luxurious accommodations to the party, with arrival in Honolulu on Saturday morning, June 26. The party will stay at the Royal Hawaiian Hotel on Waikiki Beach. The return trip will begin at 4:00 p. m., July 3, aboard the S. S. Lurline, with arrival in Los Angeles on July 8. The party will spend four and a half days on this palatial ship, which is operated by the Matson Lines. The entire trip will require 13 days.

Prepared by the Washington Office of the American Medical Association.

MEDICAL NEWS

ARIZONA

Hospital News.—On recommendation of the Maricopa County Medical Society, Dr. Charles Kalil has been appointed medical director of the Maricopa County General Hospital and Clinics, Phoenix. Dr. Kalil, who served his internship at Grady Memorial Hospital in Atlanta, Ga., was a captain in the U. S. Army Medical Corps during World War II.

Medical Examiners Appointed.—Gov. Howard Pyle has appointed Drs. O. Jocevious Farness, Tucson, Maurice R. Richter, Phoenix, and Harry T. Southworth, Prescott, members of the Arizona State Board of Medical Examiners, each for a term of three years. Drs. Carl H. Gans, Morenci, and Abe I. Podolsky, Yuma, incumbents, complete the membership.

CONNECTICUT

Fall Lecture Series.—The program committee of the Hartford Medical Society announces the following fall series of lectures, which will be held in the Hunt Memorial Building, 38 Prospect St., Hartford, at 8:30 p. m. on the dates specified. All physicians are cordially invited.

Oct. 5, George Crile, Cleveland, Medical Versus Surgical Treatment of Thyrotoxicosis.
Oct. 19, Elliott P. Joslin, Boston, Clinical Application of Statistical Studies in Diabetes.
Nov. 2, Emil Novak, Baltimore, Female Sex Hormones.
Nov. 16, Herrman L. Blumgart, Boston, Angina Pectoris and Its Treatment.
Dec. 7, Charles P. Bailey, Philadelphia, Criteria and Results of Cardiac Surgery in Children.
Dec. 21, Mr. Cyril Coleman, Hartford, Legal Aspects of Medical Practice.

Personal.—Dr. Frank L. Phillips, New Haven, was given a farewell reception by his associates on the occasion of his retirement from the department of university health at Yale University, New Haven, after 32 years of service.——Dr. Max Caplan has been appointed assistant clinical professor of medicine at Yale University School of Medicine. Formerly chief of medicine at the Meriden Hospital, he retains the position of senior attending physician.——Dr. William J. H. Fischer, who has practiced in Milford for 41 years, has been selected as Milford's man of the year by Devon Post 7788, Veterans of Foreign Wars, "for his courageous leadership in providing more adequate hospital facilities for Milford."——Dr. Ernest Rosenthal, Hartford, has been appointed to the staff of the section of ophthalmology, Yale University School of Medicine. He will head the division of eye photography that will record unusual external and fundus eye pathology.

ILLINOIS

Directory of Mental Health Resources.—The Illinois Society for Mental Health announces publication of a new edition of the "Directory of Mental Health Resources in Illinois." This 84 page booklet includes descriptive listings of general hospitals with psychiatric units, guidance and counseling services, and outpatient clinics; private sanitariums; public hospitals; residential treatment centers for children; rest homes for mental patients; and day and residential schools for the mentally retarded. It defines the mental health programs of administrative and coordinating agencies throughout the state of Illinois. The directory may be obtained for $1.50 from the Illinois Society for Mental Health, 123 W. Madison St., Chicago 2.

Chicago

Chemical Research on Cancer.—At its annual meeting in the Conrad Hilton Hotel, the week of Sept. 6, the American Chemical Society will present recent chemical cancer research. Symposiums will be held on "Chemical Factors Affecting Cellular Growth" and "Biological Approaches to Viral Chemotherapy." Reports on antituberculosis agents, compounds to control high blood pressure, local anesthetics, and antispasmodics also are scheduled by the medicinal division. Dr. Leon O. Jacobson, director of the Argonne Cancer Research Hospital, Chicago, will survey "Objectives in Medical Use of Radioisotopes and High Energy Radiation," at a divisional luncheon on Wednesday. Dr. Albert Tannenbaum, director of the department of cancer research, Medical Research Institute, Michael Reese Hospital, will read a paper on "Nutritional Factors Affecting the Growth of Neoplasms." Others who will participate in the presentations include Drs. John H. Heller, New Haven, Conn., I. William McLean Jr., Detroit, and Laurella McClelland, Rahway, N. J.

IOWA

General Practitioners Meet in Des Moines.—The annual meeting of the Iowa Academy of General Practice will be held at the Hotel Savery, Des Moines, Sept. 24-25, under the presidency of Dr. Joseph G. Fellows, Ames. A symposium on peripheral vascular disease will be presented Thursday morning by Drs. Maurice T. Bates and Emmet T. Scales, Des Moines. At 2 p. m. Dr. Norman B. Nelson, dean, State University of Iowa College of Medicine, Iowa City, will deliver an address. Friday will be devoted to a symposium on peptic ulcer, presented by the following members of the faculty of the University of Minnesota Medical School, Minneapolis: Drs. F. John Lewis, James G. Myhre, Clarence K. Aldrich, and Charles M. Nice. Dr. F. Tulley Hallam, medical director, Bankers Life Co., Des Moines, will address the luncheon meeting on "Life Insurance Examinations."

LOUISIANA

Dr. Holbrook Retires.—Dr. Charles S. Holbrook, professor of clinical psychiatry in the Tulane University of Louisiana School of Medicine, New Orleans, retired from the faculty July 1, after an affiliation of 33 years. Dr. Holbrook was formerly assistant superintendent of the East Louisiana State Hospital at Jackson and since 1923 has served as head of the neuropsychiatric clinic at Touro Infirmary, New Orleans. He is consultant in neuropsychiatry at Flint-Goodrich Hospital of Dillard University and a member of the senior staff at De Paul Sanitarium, New Orleans.

MINNESOTA

Dr. Wells Honored.—Dr. Arthur H. Wells, Duluth, has been awarded the American Cancer Society's medal for Minnesota's 1953 "Man of the Year" in cancer control. Formerly president of the Minnesota division, he has served also on its board of directors for eight years. Dr. Wells is chairman of the cancer committee of the Minnesota State Medical Society. He was recently selected as editor of *Minnesota Medicine.*

Multiple Sclerosis Diagnostic Clinic.—The University of Minnesota Medical School, Minneapolis, announces the opening of a diagnostic clinic for multiple sclerosis at the University of Minnesota Hospitals under the supervision of the division of neurology, with Dr. Charles Van Buskirk, assistant professor of neurology, in charge. Patients, referred by their family physicians, will go by appointment directly to the multiple sclerosis clinics and, when necessary, will be admitted to the hospital for special studies. After a preliminary survey, most patients will be sent back to their family physicians with recommendations.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

Personal.—Dr. E. Mendelssohn Jones, chief, surgical division, the Ancker Hospital, St. Paul, since 1948, was recently elected chief emeritus of the section. Dr. Jones, who is a past president of the Ramsey County Medical Society, the Minnesota State Medical Association, and the Minnesota Academy of Medicine, was recently elected secretary of the state board of medical examiners.——Dr. Edgar E. Heller, Mankato, has received an award for meritorious service in Korea. The citation reads, in part, ". . . As commanding officer and medical officer of three widely separated medical detachments, Lieutenant Heller traveled many miles over rough terrain to carry out his assignment in the most effective possible manner. Untrained in Army administrative routine, he nevertheless devised methods which enabled him to supervise the operation of the three detachments with great efficiency. . . ."

MISSOURI

Dr. Teachenor Honored.—Dr. Frank R. Teachenor, Kansas City, a past president of the Jackson County Medical Society, has received the society's merit award with gold key in recognition of "his scientific work in neurosurgery and long service to his profession." Dr. Teachenor, clinical professor of surgery at the University of Kansas School of Medicine, Kansas City, Kan., has practiced medicine for 42 years. In 1939, the American Legion of Kansas City cited him for his efforts in the rehabilitation of crippled children. In 1946, he served as president of the Harvey Cushing Society.

NEW YORK

Society News.—The Nassau Pediatric Society recently named Dr. Martin J. Glynn, Rockville Centre, president, and re-elected Dr. David J. Posner, Levittown, secretary. Meetings will be held at the Garden City Hotel, 7th and Park Ave., Garden City, L. I., on the second Monday of October and December, 1953, and February, April, and June, 1954, at 7:30 p. m.

State Forms Health Research Corporation.—The New York State Department of Health, Albany, announces the organization of Health Research, Inc., a nonprofit corporation to promote research in the cause and treatment of diseases. The corporation will assist in developing the research facilities of the state and local health departments by means of grants given for research in any specific disease field. The new organization enables persons or corporations wishing to assist in financing specific research projects conducted by the state to give money solely for this purpose. Directors of the new corporation include Drs. Hollis S. Ingraham, deputy state health commissioner; Morton L. Levin, assistant commissioner for medical services; Gilbert J. Dalldorf, assistant commissioner for laboratories and research; George E. Moore, director of the Roswell Park Memorial Institute, Buffalo; and Mr. John P. Coffey, assistant director of the office of business administration.

New York City

First Harvey Lecture.—Claude Fromageot, professor of biological chemistry, faculty of sciences, University of Paris, France, will deliver the first Harvey lecture of the 1953-1954 series at the New York Academy of Medicine, Sept. 24, on "Metabolism of Sulfur and Its Relations to General Metabolism."

Personal.—Dr. Thomas D. Dublin, executive director of the National Health Council since September, 1948, has resigned as of Oct. 1.——Dr. Michael G. Mulinos, associate professor of physiology and pharmacology, New York Medical College (Flower and Fifth Avenue Hospitals) has been appointed medical director for Commercial Solvents Corporation Pharmaceuticals.——Dr. Desmond Slevin has joined the medical department of Winthrop-Stearns, Inc., as associate medical director. Born in Dublin, Eire, Dr. Slevin came to the United States in 1950 and has served as resident physician at Manhasset Medical Center Hospital and as resident in psychiatry at Central Islip (N. Y.) State Hospital.——Dr. James W. Smith, clinical professor of ophthalmology, Post-Graduate Medical School of the New York-Bellevue Medical Center, has been elected president of the medical advisory board at the Hospital for Joint Diseases.

Damon Runyon Cancer Grants.—A continuing grant of $81,680 to the New York University-Bellevue Medical Center for a study under the direction of Norton Nelson, Ph.D., associate professor of industrial medicine, to determine the effect of environment on cancer of the respiratory system was the principal allocation among $179,830 in June grants made by the Damon Runyon Memorial Fund for Cancer Research. Fellowships totaling $16,700 were approved for four research scientists engaged in various projects of cancer study. These grants brought the total amount distributed in research to $6,921,856. This sum in the last seven years has been allocated in 368 institutional grants and 249 fellowships in 166 institutions, in 46 states, the District of Columbia, and 14 foreign countries.

OHIO

Reappoint Dr. Porterfield State Health Director.—The Ohio senate has confirmed Gov. Frank J. Lausche's appointment of Dr. John D. Porterfield III, Columbus, as director of the Ohio Department of Health for a second term of five years. Dr. Porterfield was commissioned in the U. S. Public Health Service in June, 1939. He spent 14 months in the Caribbean area serving as U. S. P. H. S. venereal disease consultant and director at the School of Tropical Medicine, San Juan, Puerto Rico, and was released from active duty with the U. S. P. H. S. to accept his present position.

PENNSYLVANIA

Joint Meeting of Pathologists.—A joint meeting of the Middle Eastern District, College of American Pathologists, and the Pennsylvania Association of Clinical Pathologists will be held at the Roosevelt Hotel, Pittsburgh, Sept. 18-19. Dr. James B. Arey, Philadelphia, will conduct a slide seminar on "Tumors of Children." Participants in a panel discussion on "The County Health Unit" include Drs. Thomas W. McCreary, Rochester; E. E. Aegerter, Frederick W. Sunderman, and Robert C. Horn Jr., Philadelphia; and Frank J. Dixon Jr., Robert C. Grauer, and Louis Goodman, Pittsburgh.

Philadelphia

Appoint Professor of Occupational Medicine.—Dr. F. Benedict Lanahan, medical director for the Electric Storage Battery Company, has been appointed professor of occupational medicine at the Woman's Medical College of Pennsylvania. He was previously assistant plant physician for E. I. duPont de Nemours and Company in Arlington, N. J., and medical director for Hilton-David Chemical Corporation and Davidson Chemical Corporation, Cincinnati. Dr. Lanahan, who has held teaching posts at Jefferson Medical College of Philadelphia, St. Joseph's College, and the University of Cincinnati College of Medicine, is past chairman of the industrial medicine section, Philadelphia County Medical Society; past president of the Philadelphia section, American Industrial Hygiene Association; president of Philadelphia Industrial Medical Association; and a member of the medical advisory board of the National Association of Manufacturers.

European Tour.—Dr. Stuart Mudd, professor of microbiology, and Dr. Edward D. Delamater, research professor of dermatology and microbiology, University of Pennsylvania School of Medicine, are in Europe attending, in Nice, France, the International Union of Biological Sciences, of which Dr. Mudd is American secretary; the International Congress of Genetics, at Bellagio, Italy; and the International Congress of Microbiology in Rome, Italy. At the International Congress of Genetics, Dr. Delamater was chairman of the section on bacterial chromosomes and presented a paper on the subject. At the Congress of Microbiology, he presented a paper. Drs. Mudd and Delamater collaborated in the presentation of evidence lately obtained relative to the action of the new antibiotic drugs within the structure of the human cell. Dr. Delamater will remain in Europe until mid-November visiting medical centers to study laboratory methods used in investigations of cytogenetics.

RHODE ISLAND

Fiske Fund Contest.—A prize of $250 is offered by the trustees of the Fiske Fund of the Rhode Island Medical Society for the best dissertation on "Recent Advances in Cardiac Surgery." The entry will be particularly graded on the basis of original work by the author and his observation of patients. It must be typewritten and double spaced on standard typewriter paper and should not exceed 10,000 words. Entries, inscribed with motto and accompanied by a sealed envelop bearing the same motto and containing the contestant's name and address, should be sent on or before Dec. 2 to the secretary to the trustees, John E. Farrell, Sc.D., 106 Francis St., Providence 3.

TENNESSEE

Medical Assembly in Chattanooga.—The Tennessee Valley Medical Assembly will convene under the sponsorship of the Chattanooga-Hamilton County Medical Society at Read House, Chattanooga, Sept. 28-29. Leo Brown, Chicago, A. M. A. Director of Public Relations will address the banquet Monday on "Medicine's Golden Opportunity." Speakers at the scientific sessions include:

Philip Thorek, Chicago, Acute Abdomen.
Richard W. TeLinde, Baltimore, (1) Carcinoma of the Cervix. (2) Pelvic Endometriosis.
Paul D. White, Boston, (1) Hypertensive Heart Disease a Generation Ago and Now. (2) Notes on Coronary Heart Diseases.
Charles W. Mayo, Rochester, Minn., Alex Stewart Memorial Lecture, Colon Surgery.
Robert B. Lawson, Winston-Salem, N. C., To Treat or Not to Treat.
John R. Heller, Bethesda, Md., Pathogenesis of Carcinoma.
John B. Youmans, Nashville, Anemia and Nutrition.
Richard B. Cattell, Boston, (1) Advances in Pancreatic Surgery. (2) Surgical Treatment of Gastric and Duodenal Ulcers.
H. Earle Conwell, Birmingham, Ala., Do's and Don't's in Fracture Treatment.
George Crile Jr., Cleveland, (1) Diseases of the Thyroid Gland. (2) Bleeding Esophageal Varices.

For information write: Tennessee Valley Medical Assembly, 612 Medical Arts Bldg., Chattanooga.

TEXAS

Industrial Health Conference.—The Texas Heart Association and the Houston District Chapter are cooperating with other groups in sponsoring an Industrial Health Conference, Oct. 1-3. The luncheon period and afternoon sessions on Thursday will be devoted to a program on "The Heart in Industry." Luncheon speakers will be Dr. Robert L. King, Seattle, president of the American Heart Association, who will discuss "What the American Heart Association Offers Industry," and Dr. Harold M. Marvin of Yale University School of Medicine, New Haven, Conn., who will speak on "The Executive and His Heart Attack." Dr. Sidney Schnur, Houston, will preside at the afternoon panel meeting for which the following program has been announced:

Harold M. Marvin, New Haven, The Physician's Viewpoint.
James J. Healy, How the Worker Views It.
Mr. Albert Jones, According to the Medicolegal Angle.
Mr. Stokes Marshall, As Viewed by the Personnel Director.
E. Ghent Graves, A Problem for the Insurance Carrier.

WEST VIRGINIA

Society News.—A recent meeting of the West Virginia Academy of General Practice elected Drs. Jacob C. Huffman, Buckhannon, president; Clark K. Sleeth, Morgantown, vice-president; and Halvard Wanger, Shepherdstown, secretary-treasurer (reelected).——The West Virginia Diabetes Association, recently accepted as a new section by the West Virginia State Medical Association, has elected the following officers: president, Dr. Richard N. O'Dell, Charleston; president-elect, Dr. John H. Gile, Parkersburg; vice-president, Dr. Archie C. Thompson, Elkins; and secretary-treasurer, Dr. Ralph H. Nestmann, Charleston. Drs. Marion F. Jarrett, Charleston, Halvard Wanger, Shepherdstown, and Oliver H. Brundage, Parkersburg, were elected members of the board of directors. ——The West Virginia *Pediatrics Society* is being organized within the framework of the West Virginia State Medical Association's section on pediatrics. Plans call for the sponsorship of two scientific sessions annually, one in the northern and the other in the southern part of the state. Beside pediatricians, the new society will include general practitioners interested in pediatrics. Dr. Russell C. Bond, Wheeling, is chairman of the section on pediatrics, and Dr. Helen B. Fraser, Charleston, is secretary.——The West Virginia Association of Pathologists recently elected Drs. Elmer E. Myers, Philippi, president; Peter P. Ladewig, Montgomery, president-elect; and Richard C. Neale, Bluefield, secretary-treasurer. ——The West Virginia Society of Anesthesiologists named Drs. Lester D. Norris, Fairmont, president; Newman H. Newhouse, Charleston, vice-president; and John F. Morris, Huntington, secretary-treasurer.——The following officers were elected by the West Virginia Obstetrical and Gynecological Society: Drs. Everett W. McCauley, Bluefield, president; Ulysses G. McClure, Charleston, vice-president; and Angelo J. Villani, Welch, secretary-treasurer.

WISCONSIN

Medical Art Exhibit at Milwaukee.—An art exhibition entitled "The Story of Medicine in Art" will be held at the Milwaukee Art Institute Sept. 11 to Oct. 25, under the cosponsorship of the Wisconsin State Medical Association, Milwaukee County Medical Society, and the Boston Store of Milwaukee. The exhibit will include paintings, drawings, graphics, sculpture, manuscripts, letters, medals, stamps, and other art objects related to medicine. Exhibits are being sent by numerous museums, private collectors, and artists.

Chest Physicians' Meeting.—The Wisconsin Chapter of the American College of Chest Physicians will hold its annual meeting at the Hotel Schroeder, Milwaukee, Oct. 4. The following program will be presented at 2 p. m.:

Electrocardiographic Problems in Daily Practice, George A. Hellmuth, Chicago.
Granulomatous Lung Disease, Joseph M. Lubitz, Milwaukee.
Surgical Treatment of Mitral and Aortic Stenosis (motion pictures), Alfred Goldman, Los Angeles.
Inhalation of Dihydrostreptomycin Dust in Treatment of Diseases of the Respiratory Tract, Mary Karp, et al., Chicago.
Diseases of the Trachea (motion pictures), Kenneth C. Johnston, Chicago.

Dr. Edgar Mayer, New York, will speak on "Palliative Treatment of Inoperable Bronchogenic Carcinoma" at the dinner, 6 p. m., in the Club Rooms, 3rd floor.

GENERAL

Biological Photographic Meeting.—The annual meeting of the Biological Photographic Association will convene at the Hotel Statler, Los Angeles, Aug. 31 to Sept. 3. The Monday afternoon meeting will be held at the Walt Disney Studios, 1:15, where luncheon will be followed by a demonstration and lecture on animation and the showing of films. The evening session will include the projection of color slides. The program includes:

David S. Ruhe, Chicago, Clinical Photographer's Role in Production of Short Short Medical Films.
Ernest Rosenthal, New Haven, Conn., Bronchovascular Anatomy.
Philip D. Bonnet, Boston, Hospitals and Medical Photography.
John M. Langton, Glendale, Calif., Anterior Segment Photography with Speed Flash.

Cruise Congress to South America.—The Pan American Medical Association announces that its ninth International Cruise Congress to South America and the West Indies will be held on board the S. S. Nieuw Amsterdam, sailing from New York Jan. 6 and returning Jan. 22, 1954. Scientific sessions and panel discussions will be held at sea and in port. Ports to be visited include Caracas, Venezuela; Curaçao; St. Thomas, Virgin Islands; San Juan, Puerto Rico; Cuidad Trujillo, Dominican Republic; and Havana, Cuba. The American Express Company, which will handle all reservations subject to the approval of the association, requires an initial deposit of $200 for each passenger ($35 of which will be deducted for the Pan American Medical Association to cover the registration fee for each passenger).

Pan American Medical Women's Alliance.—The congress of the Pan American Medical Women's Alliance will convene at the Beekman Towers Hotel, 1st Ave. and 49th St., New York, Sept. 24 to Oct. 1. Scientific sessions will be followed by round table luncheon discussions with lecturers speaking Spanish and English. Through the sponsorship of New York medical women, those interested in a special field will have opportunities to attend clinics of their choice. The Medical Women's Association of New York, serving as host, has planned a program of tours of the New York Hospital-Cornell Medical Center and Columbia University-Presbyterian Medical Center, a boat trip around Manhattan Island, tour and luncheon at the United Nations, visits to Radio City and the Empire State Building, and a drive to Hyde Park, N. Y. Registration fee is $10; registration chairman, Dr. Ina A. Marsh, 140 Linwood Ave., Buffalo 9.

Grant to Multiple Sclerosis Society.—A grant of $34,354 has been awarded to the National Multiple Sclerosis Society by the Kresge Foundation of Detroit in memory of its former president, the late Paul W. Voorhies. It is specified that the grant shall further the multiple sclerosis research project at the New York University-Bellevue Medical Center, to which the society has already allocated over $100,000 of its research funds. The grant will enable the staff to continue research that involves: (1) further investigation of visual disturbances produced by abnormal eye movements in patients with multiple sclerosis; search for drugs that will alter or abolish these disturbances, (2) study of drugs aimed at alleviating muscle spasticity, (3) study of adhesive properties of blood platelets and its reflection of activity in multiple sclerosis, (4) study of cerebral spinal fluids of patients with multiple sclerosis and other neurological disorders, and (5) new techniques and modes of therapy evaluated for the study of multiple sclerosis and other demyelinating diseases.

Medical Writers Meeting.—The American Medical Writers' Association will hold its 10th annual meeting at the Elks Club, Springfield, Ill., Sept. 23, under the presidency of Dr. Lewis J. Moorman, Oklahoma City. The session will open with the following symposium on medical writing:

Julius Jensen, St. Louis, Writing for the General Practitioner.
Stewart G. Wolf, Oklahoma City, Writing for the Medical Specialties.
Theodore R. Van Dellen, Chicago, Writing for the Public by the M.D.

After discussion by Drs. Richard M. Hewitt, Rochester, Minn., and Lee D. Van Antwerp, Skokie, Ill., there will be a presentation on medical writing for medical students by Dr. Walter Reginald Bett, London, England, who will speak on "The Desirability and Methods of Teaching Medical Writing to Senior Medical Students," and Dr. Dean F. Smiley, Chicago, who will discuss "What Medical Schools Can Do to Improve Medical Writing." In the afternoon there will be a symposium on medical writing as seen by a medical editor, a director of a university press, a layman, a medical illustrator, and an undergraduate student of medicine. At the banquet in the Hotel Abraham Lincoln, Dr. Bett will present "A Little Judicious Levity."

American Hospital Association Meeting.—The American Hospital Association will hold its annual convention in San Francisco, Aug. 31 to Sept. 3, under the presidency of Dr. Edwin L. Crosby, Chicago, who will deliver the opening address on Monday, 2:15 p. m., in the Civic Auditorium. The theme of this session will be "Marshaling the Forces in the Hospital." Dr. Crosby's talk will be followed by an address on "One of Our Greatest Resources" by the Hon. Oveta Culp Hobby, secretary, Department of Health, Education, and Welfare, Washington, D. C. Dr. Lewis A. Alesen, Los Angeles, will serve as moderator for a panel discussion "Where Should We Focus Our Concern?" in which Dr. Stafford L. Warren, Los Angeles, will speak for the medical staff. Drs. E. Dwight Barnett, New York, and Robin C. Buerki, Detroit, will participate in a discussion on "The Development of a Solid Financial Base" in development of the Tuesday morning theme, "Factors Affecting Hospital Care." Tuesday afternoon will be devoted to a presentation entitled "The Community Needs a Hospital—How We Organized Our Community for Support," a case history of the Santa Monica (Calif.) Hospital. Serving on the Santa Monica panel will be Drs. Adolph W. Kosky, William C. Bradbury, and David H. Sprong Jr. Wednesday morning "Aids to Help Make Our Jobs Easier" will be presented. Dr. Harry E. Peters, Oakland, will speak on medical staff-trustee relationships, and Dr. Charles U. Letourneau, Chicago, will participate in a panel discussion entitled "These Aids Are Available from the American Hospital Association." Dr. Anthony J. J. Rourke, San Francisco, will be master of ceremonies at a sisters luncheon at the Palace Hotel, Wednesday, 12:30 p. m. At the annual banquet at the Palace Hotel, Thursday, the award of merit will be presented to Dr. Basil C. MacLean, director of Strong Memorial Hospital, Rochester, N. Y. Entertainment will be furnished by Edgar Bergen and Charlie McCarthy.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories, and possessions in the weeks ended as indicated:

CANADA

International Physiological Congress.—The 19th International Physiological Congress will be held in Montreal, Aug. 31 to Sept. 4, under the presidency of Dr. Charles H. Best, Toronto. Special symposiums, most of which will be held at the Université de Montréal, include: hemodynamics in small vessels, physiology of cold, mechanism of formation of the thyroid hormone, metabolic influence of insulin, and reflexes from the cardiac and pulmonary areas. The congress will be followed by a pharmacologists' meeting, sponsored jointly by the Canadian Physiological Society and the International Pharmacological Committee at McGill University, Sept. 5. The scientific program will consist of symposiums on "The Pharmacology of Renal Tubular Mechanisms" and "The Actions of Drugs at Autonomic Ganglia."

LATIN AMERICA

Meeting on Radiology.—The fourth Brazilian Week on Radiology will be held in Curitiba, Parana, Brazil, Sept. 27 to Oct. 3 under the auspices of the state government. Official topics include "Roentgen Diagnosis in Nontuberculous Pneumopathies," "Roentgen Changes of Bones in Endocrinopathies," "Roentgen Therapy of Breast Cancer," and "Roentgen Therapy in Dermatology." Information may be obtained from the Secretary General, Rua Candido Lopes 40, 1° Curitiba, Parana, Brazil.

FOREIGN

Meeting of Sports Physicians.—The health commission of the Austrian United Nations Associations announces the International Congress for Sports Physicians at Obertraun, Hallstättersee, Sept. 11-13.

Society for the Study of Biological Rhythms.—The fourth meeting of the International Society for the Study of Biological Rhythms will be held at Basel, Switzerland, Sept. 18-19. Among the 44 papers to be presented are: "Experimental Production of Cycles in Behavior and Physiology of Animals," Curt P. Richter, Ph.D., Baltimore, and "Recent Study on the Development of the Diurnal (24-Hour) Sleep-Wakefulness Rhythm in the Infant," Nathaniel Kleitman, Ph.D., and Mr. Theodore G. Engelmann, Chicago.

International Neurological Congress.—The fifth International Neurological Congress will be held in Lisbon, Portugal, Sept. 7-12. Topics for discussion include vascular diseases of the brain, parietal lobe, and metabolic diseases of the brain. Dr. Seymour S. Kety, Bethesda, Md., will present a paper on "Physiopathology of Cerebral Circulation in the Vascular Diseases of the Brain." A meeting in commemoration of the birth of Ramón y Cajal. founder of the Spanish School of Neurologists and a Nobel Laureate in 1906, will be held in Madrid immediately after the congress (Sept. 13-14). Dr. Henry Alsop Riley, New York, is chairman of the committee for the United States, and Dr. H. Houston Merritt, New York, is secretary.

The Association International for Multiple Sclerosis of the National Multiple Sclerosis Society will hold its meeting simultaneously with that of the International Neurological Congress and will use the same headquarters, the University Hospital of Lisbon. There will be a cocktail party and a dinner at the Club de Tenis de Lisboa, Parque do Monsanto, Sept. 6, 7:30 p. m.

International Society of Surgery.—The 15th congress of the International Society of Surgery will be held Sept. 14-20 in the Nouvel Hôpital de la Faculté, Lisbon, Portugal. Participating in the discussion on regeneration of tissues will be Drs. Valy Menkin, Philadelphia, Edward L. Howes and Alexander Brunschwig, New York, Samuel C. Harvey, New Haven, Conn., Henry G. Schwartz, St. Louis, Glenn H. Algire, Bethesda, Md., Isidor S. Ravdin, Philadelphia, and Charles M. Pomerat, Ph.D., Galveston, Texas. During the Friday morning session devoted to aneurysms, papers will be presented by Drs. Isidore Cohn, New Orleans, Geza deTakats and Conrad L. Pirani, Chicago, Emile F. Holman, San Francisco, and Arthur H. Blakemore, New York. Participating in the discussions will be Drs. Alexander W. Blain, Detroit, Michael E. DeBakey and Denton A. Cooley, Houston, Texas, Frank Gerbode, San Francisco, Howard R. Mahorner, New Orleans, Louis G. Herrmann, Cincinnati, and James C. White, Boston.

Angiologists Meet in Lisbon.—The International Society of Angiology will hold its second congress at the Novo Hospital Escolar, Campo Grande, Lisbon, Portugal, Sept. 18-20 under the presidency of Dr. Emile F. Holman, San Francisco. Friday will be devoted to a symposium on aneurysms in joint session with the International Society of Surgery. A symposium on mitral valve surgery will be held Saturday, and an angiology forum on Sunday. The inaugural session of the society will be held jointly with that of the International Society of Surgery, Sept. 14, 11 a. m., and the executive session will convene Sept. 18 at 2 p. m. Many physicians from the United States are scheduled to participate in the program. These, together with their first presentations, include:

Isidore Cohn, New Orleans, Homage to Professor Rudolph Matas.
Geza deTakats and Conrad L. Pirani, Chicago, Aneurysms: General Considerations.
Emile F. Holman, San Francisco, Fundamental Principles Governing the Care of Traumatic Arteriovenous Aneurysms.
Arthur H. Blakemore, New York, Aneurysms of the Aorta.
Harris B. Shumacker Jr., Indianapolis, Tests for and Means of Improving the Collateral Circulation in Cases of Aneurysms and Arteriovenous Fistulas.
Louis G. Herrmann, Cincinnati, Surgical Obliteration of Popliteal Aneurysms.
James C. White, Boston, Aneurysms of the Aorta.
Howard R. Mahorner and Rowena Spencer, New Orleans, Arterial Shunts: A Technique for Replacing Segments of Large Vessels.
Frank L. Gerbode, San Francisco, Use of Blood Vessel Grafts in the Repair of Major Vessels.
Michael E. DeBakey and Denton A. Cooley, Houston, Treatment of Aneurysms of the Aorta by Resection and Restoration of Continuity With or Without Aortic Graft.
Alexander Blain III, Detroit, Surgical Aspects of Dissecting Aortic Aneurysms.
Elliott S. Hurwitt, New York, Demonstration of the Function of the Mitral Valve (Film).
Charles P. Bailey, Hauck E. Bolton, and M. C. De Almeida, Philadelphia, Indications and Surgical Management of Patients with Mitral Stenosis.
Dwight E. Harken, Boston, Evaluation of Results in Operations for Mitral Stenosis.
George H. Humphreys II and Ralph A. Deterling Jr., New York, Observations on the Etiology of Constrictive Pericarditis.
Saul S. Samuels, New York, A Comparative Study by an Electronic Method of the Vasodilating Effect of Various Drugs.
Henry Haimovici, New York, Experimental Stenosing Arterial Thrombosis: Physiopathologic Considerations.
Edwin J. Wylie, San Francisco, Thromboendarterectomy.
Ormand C. Julian, William J. Grove, and William S. Dye, Chicago, Resection of Aortic Bifurcation with Graft Replacement.
Robert R. Linton, Boston, Surgical Treatment of the Postphlebitic Syndrome with Ulceration of the Lower Extremity.

CORRECTIONS

Effects of HPC and Aspirin on Rheumatic Fever.—In the abstract on this subject on page 1265 of THE JOURNAL July 25, 1953, the term "probenecid" was mistakenly substituted for HPC or 3-hydroxy-2-phenylcinchoninic acid.

Postgraduate Courses.—The courses listed below in THE JOURNAL, June 13, 1953, page 631, were incorrectly credited to Mt. Sinai Hospital, New York, instead of the Montefiore Hospital, New York:

Medicine PM 60—Cardiology I
Medicine PM 62—Cardiology II
Medicine PM 63—Cardiology III
Medicine PM 64—Recent Advances in Diagnosis and Surgical Treatment of Heart Diseases
Medicine PM 66—Hematology
Medicine PM 67—Advanced Hematology
Medicine PM 65—Peripheral Vascular Diseases
Medicine PM 72—Neoplastic Diseases

Hypertension During Transurethral Resection.—In the answer to the query by this title in THE JOURNAL, Aug. 15, 1953, page 1581, the words "sodium chloride" were erroneously inserted in the copy by the manuscript editor after the word "isotonic" and did not appear in the consultant's original copy.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1953 Clinical Session, St. Louis, Dec. 1-4.

1954 Annual Session, San Francisco, June 21-25.

1954 Clinical Session, Miami, Florida, Nov. 30-Dec. 3.

1955 Annual Session, Atlantic City, N. J., June 6-10.

1955 Clinical Session, Boston, Nov. 29-Dec. 2.

National Conference on Physicians and Schools, Moraine-on-the-Lake Hotel, Highland Park, Ill., Sept. 30-Oct. 2. Dr. W. W. Bauer, 535 N. Dearborn St., Chicago 10, Director.

Public Relations Institute, Drake Hotel, Chicago, Sept. 2-3. Mr. Leo E. Brown, 535 North Dearborn St., Chicago 10, Director.

American Academy of Ophthalmology and Otolaryngology, Palmer House, Chicago, Oct. 12-16. Dr. W. L. Benedict, 100 First Avenue Bldg., Rochester, Minn., Executive Secretary.

American Academy of Pediatrics, Municipal Auditorium, Miami, Fla., Oct. 6-9. Dr. E. H. Christopherson; 610 Church St., Evanston, Ill., Secretary.

American Association of Medical Clinics, Congress Hotel, Chicago, Oct. 9-11. Dr. Edwin P. Jordan, P. O. Box 114, Charlottesville, Va., Executive Director.

American Association of Medical Record Librarians, Palace Hotel, San Francisco, Oct. 5-9. Miss Doris Gleason, 510 N. Dearborn St., Chicago 10, Executive Secretary.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, The Homestead, Hot Springs, Va., Sept. 10-12. Dr. William F. Mengert, 2211 Oak Lawn Ave., Dallas, Texas, Secretary.

American Association for the Surgery of Trauma, Drake Hotel, Chicago, Oct. 1-3. Dr. James K. Stack, 700 North Michigan Blvd., Chicago, Secretary.

American College of Surgeons, Conrad Hilton Hotel, Chicago, Oct. 5-9 Dr. Michael L. Mason, 40 East Erie St., Chicago, Secretary.

American Congress of Physical Medicine, Palmer House, Chicago, Aug. 31-Sept. 4. Dr. Walter J. Zeiter, 30 North Michigan Ave., Chicago 2, Executive Director.

American Dietetic Association, Los Angeles, Aug. 24-28. Miss Ruth M. Yakel, 620 N. Michigan Ave., Chicago 11, Executive Secretary.

American Fracture Association, Mission Inn, Riverside, Calif., Oct. 12-15 Dr. H. W. Wellmerling, 120 S. LaSalle St., Chicago 3, Secretary.

American Hospital Association, San Francisco, Aug. 31-Sept. 3. Mr. George Bugbee, 18 East Division St., Chicago 11, Executive Director.

American Medical Writers' Association, Elk's Club, Springfield, Ill., Sept. 23. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

American Roentgen Ray Society, Netherland Plaza, Cincinnati, Sept. 29-Oct. 2. Dr. Barton R. Young, Germantown Hospital, Philadelphia 44, Secretary.

American Society of Anesthesiologists, Olympic Hotel, Seattle, Oct. 6-9. Dr. J. Earl Remlinger Jr., Room 1101, 188 W. Randolph St., Chicago, Secretary.

American Society of Clinical Pathologists, Drake Hotel, Chicago, Oct. 12-16. Dr. Clyde G. Culbertson, 1040 W. Michigan St., Indianapolis, Secretary.

American Society for Pharmacology and Experimental Therapeutics, Fall Meeting, Yale University, New Haven, Conn., Sept. 7-9. Dr. Carl C. Pfeiffer, 1853 West Polk St., Chicago 12, Secretary.

Association of Life Insurance Medical Directors of America, Hotel Statler, New York, Oct. 14-16. Dr. Henry B. Kirkland, P. O. Box 594, Newark 1, N. J., Secretary.

Association of Medical Illustrators, Sheraton Hotel, Baltimore, Oct. 5-7. Miss Evelyn J. Erickson, 1512 St. Antoine St., Detroit 26, Secretary.

Biological Photographic Association, Hotel Statler, Los Angeles, Aug. 31-Sept. 3. Miss Jane H. Waters, 533 West 57th St., New York 19, Secretary.

Central Neuropsychiatric Association, Claypool Hotel, Indianapolis, Oct. 15-17. Dr. Hamilton Ford, 112 North Blvd., Galveston, Texas, Secretary.

College of American Pathologists, Drake Hotel, Chicago, Oct. 12-16. Dr. Harry P. Smith, 203 N. Wabash Ave., Chicago 1, Secretary.

Colorado State Medical Society, Shirley-Savoy Hotel, Denver, Sept. 29-Oct. 2. Mr. Harvey T. Stethman, 835 Republic Bldg., Denver 2, Executive Secretary.

Delaware, Medical Society of, Hotel du Pont, Wilmington, Oct. 12-14. Dr. Andrew M. Gehret, 822 North American Bldg., Secretary.

District of Columbia, Medical Society of the, Hotel Statler, Washington, Oct. 5-7. Mr. Theodore Wiprud, 1718 M St. N.W., Washington 6, Secretary.

Gerontological Society, Mark Hopkins Hotel, San Francisco, Aug. 25-27. Dr. Nathan W. Shock, Baltimore City Hospitals, Baltimore 24, Secretary.

Gulf Coast Clinical Society, Admiral Semmes Hotel, Mobile, Ala., Oct. 15-16. Dr. William J. Atkinson Jr., 1217 Government St., Mobile 20, Ala., Secretary.

Gulf Coast Conference on Industrial Health, Shamrock Hotel, Houston, Tex., Oct. 1-3. Dr. Sidney Schnur, 411 Medical Arts Bldg., Houston 2, Tex., Vice Chairman.

Kansas City Southwest Clinical Society, Kansas City, Mo., Sept. 28-Oct. 1. Dr. W. H. Algie, 825 North 7th Street, Kansas City, Kans., Secretary.

Kentucky State Medical Association, Brown Hotel, Louisville, Sept. 22-24. Dr. Bruce Underwood, 620 South Third St., Louisville 2, Secretary.

Michigan State Medical Society, Pantlind Hotel and Civic Auditorium, Grand Rapids, Sept. 23-25. Dr. L. Fernald Foster, 606 Townsend St., Lansing 15, Secretary.

Mississippi Valley Medical Society, Springfield, Ill., Sept. 23-25. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

Montana Medical Association, Northern Hotel, Billings, Sept. 17-20. Mr. L. R. Hegland, 104 North Broadway, Billings, Executive Secretary.

National Gastroenterological Association, Hotel Biltmore, Los Angeles, Oct. 12-17. Dr. A. Xerxes Rossien, 1819 Broadway, New York 23, Secretary.

Neurosurgical Society of America, The Broadmoor, Colorado Springs, Colo., Sept. 23-27. Dr. C. D. Hawkes, 22 North Manassas St., Memphis 5, Tenn., Secretary.

Nevada State Medical Association, Carter Hotel, Elko, Sept. 24-26. Dr. William A. O'Brien III, 505 Chestnut St., Reno, Secretary.

New Hampshire Medical Society, Equinox House, Manchester, Vt., Oct. 4-6. Dr. Deering G. Smith, 44 Chester St., Nashua, Secretary.

Northern Minnesota Medical Association, Fergus Falls, Aug. 28-29. Dr. C. L. Oppegaard, Crookston, Secretary.

North Pacific Society of Internal Medicine, Harrison, B. C., Canada, Sept. 18-19. Dr. Clarence C. Pearson, 1115 Terry Ave., Seattle 1, Wash., Secretary.

North Texas-Southern Oklahoma Fall Clinical Conference, Wichita Falls, Texas, Sept. 16. Dr. C. H. Wilson, 1300 Eighth St., Wichita Falls, Texas, Secretary.

Oregon State Medical Society, Heathman Hotel, Portland, Oct. 14-17. Dr. Charles E. Littlehales, 833 S.W. Eleventh Ave., Portland 5, Secretary.

Pennsylvania, Medical Society of the State of, William Penn Hotel, Pittsburgh, Sept. 21-24. Dr. Harold B. Gardner, 230 State St., Harrisburg, Secretary.

Regional Meetings, American College of Physicians:

- North Dakota, Fargo, Sept. 12. Dr. Robert B. Radl, 221 Fifth St., Bismarck, Governor.
- Arkansas-Oklahoma, Tulsa, Okla., Sept. 19. Dr. Wann Langston, 117 North Broadway, Oklahoma City 2, Governor.
- Western New York, Syracuse, Oct. 9. Dr. E. C. Reifenstein, 109 South Warren St., Syracuse 2, Governor.
- Ohio, Dayton, Oct. 9. Dr. Charles A. Doan, Ohio State University College of Medicine, Columbus 10, Governor.
- Montana-Wyoming, Missoula, Mont., Oct. 9-10. Dr. Harold W. Gregg, 127 West Park Street, Butte, Mont., Governor.
- Southeastern—Cuba, Alabama, Florida, Georgia, South Carolina—St. Simons, Sea Island, Ga., Oct. 16-17. Dr. Carter Smith, 384 Peachtree St. N.E., Atlanta 3, Ga., Chairman.

Southwestern Surgical Congress, Hotel Utah, Salt Lake City, Sept. 21-23. Dr. C. R. Rountree, 1227 Classen St., Oklahoma City 3, Secretary.

Tennessee Valley Medical Assembly, Read House Hotel, Chattanooga, Sept. 28-29. Dr. William G. Stephenson, 612 Medical Arts Bldg., Chattanooga 3, President.

U. S. Chapter, International College of Surgeons, Waldorf-Astoria, New York, Sept. 13-17. Dr. Karl Meyer, 1516 Lake Shore Drive, Chicago 10, Secretary.

Utah State Medical Association, Salt Lake City, Sept. 10-12. Dr. Homer E. Smith, 42 South Fifth East St., Salt Lake City 2, Secretary.

Vermont State Medical Society, Equinox House, Manchester, Oct. 4-6. Dr. James P. Hammond, 542 Main St., Bennington, Secretary.

Washington State Medical Association, Olympic Hotel, Seattle, Sept. 13-16. Dr. Bruce Zimmerman, 338 White-Henry-Stuart Bldg., Seattle 1, Secretary.

Western Orthopedic Association, Sun Valley, Idaho, Oct. 5-8. Dr. Forrest L. Flashman, 1301 Spring St., Seattle 4, Secretary.

Wisconsin, State Medical Society of, Hotel Schroeder, Milwaukee, Oct. 5-7. Mr. Charles H. Crownhart, 704 East Gorham St., Madison 3, Secretary.

Regional Meeting, American College of Physicians, San Juan, Puerto Rico, Oct. 15-17. Dr. R. Rodriquez-Molina, Veterans Administration Center, San Juan, Puerto Rico, Governor.

Sectional Meeting, American College of Surgeons, London, England, May 17-19, 1954. Dr. Michael L. Mason, 40 East Erie St., Chicago 11, Ill., U. S. A., Secretary.

World Conference on Medical Education, British Medical Association House, Tavistock Square, W.C.1, London, England, Aug. 22-29. Secretariat: World Medical Association, 2 East 103d St., New York 29, N. Y., U. S. A.

World Congress of the World Confederation for Physical Therapy, London, England, Sept. 7-12. Miss M. J. Neilson, Chartered Society of Physiotherapy, Tavistock House, South, Tavistock Square, London, W.C.1, England, Secretary.

World Medical Association, The Hague, Netherlands, Aug. 31-Sept. 7. Dr. Louis H. Bauer, 345 East 46th St., New York 17, N. Y., Secretary-General.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* All centers where there are five or more candidates. Sept. 8-10 (Part I only). Candidates may file applications at any time, but the National Board must receive them at least six weeks before the date of the examination they wish to take. Exec. Sec., Dr. John P. Hubbard, 133 South 36th St., Philadelphia 4.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Written.* Various Centers, July 16, 1954. Sec., Dr. Curtiss B. Hickox, 80 Seymour St., Hartford 15.

American Board of Dermatology and Syphilology: All candidates must now pass a written examination. *Written.* Various centers, Sept. 3. *Oral.* Philadelphia, Oct. 16-18. To be eligible, candidate must complete 36 months of training before Oct. 1. Final date for filing applications was May 1. Exec. Sec., Miss Janet Newkirk, 66 East 66th St., New York 21.

American Board of Internal Medicine: *Oral.* San Francisco, Sept. 30-Oct. 2, Chicago, Nov. 30-Dec. 2. The closing date for acceptance of applications for the San Francisco and Chicago oral examination was April 1. *Written.* October 19. The closing date for acceptance of applications was May 1. Exec. Sec.-Treas., Dr. William A. Werrell, 1 West Main St., Madison 3.

American Board of Neurological Surgery: *Oral.* New Haven, October. Final date for filing application was July 1, Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, Kingshighway and Euclid Ave., St. Louis.

American Board of Neurology and Psychiatry: *Psychiatry and Neurology.* Dec. 14-15. Applications no longer being accepted. Chicago, April 29-30. Final date for filing application is Feb. 1. Sec., Dr. David A. Boyd, Jr., 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Obstetrics and Gynecology: *Written.* Various cities of the United States and Canada, Feb. 5. Application for examination or re-examination, as well as requests for resubmission of case reports, must be made prior to October 1. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: Chicago, Oct. 5-9. *Written.* Various Centers, January 1954. Final date for filing applications was July 1. Sec., Dr. Edwin B. Dunphy, 56 Ivie Road, Cape Cottage, Maine.

American Board of Orthopaedic Surgery: Chicago, January 1954. Final date for filing application is August 15. Sec., Dr. Harold A. Sofield, 122 S. Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 5-9. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City.

American Board of Pathology: *Written. Pathologic Anatomy and Clinical Pathology.* Chicago, Oct. 8-10. Sec., Dr. William B. Wartman, 303 E Chicago Ave., Chicago.

American Board of Pediatrics: *Oral.* Miami, Oct. 9-11; Indianapolis, Dec. 4-6. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Plastic Surgery: *Entire Examination.* San Diego, Oct. 29-31. Final date for receipt of case reports was June 1. Corres. Sec., Mrs. Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8.

American Board of Proctology: *Part II. Oral and Written. Anorectal Surgery and Proctology.* Philadelphia, Sept. 19. Sec., Dr. Louis A. Buie, 102-110 Second Ave. S.W., Rochester, Minn.

American Board of Radiology: *Oral. Radiology, Roentgenology, Diagnostic Roentgenology and Therapeutic Radiology.* Chicago, Dec. 6-11. Final date for filing application was July 1. Sec., Dr. B. R. Kirklin, 102-110 Second Ave. S.W., Rochester, Minn.

Board of Thoracic Surgery: *Written.* Various centers throughout the country, September 11. Final date for filing application was July 1. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2.

DEATHS

Partlow, William Dempsey ⊕ Tuscaloosa, Ala.; born Feb. 4, 1877; Medical College of Alabama, Mobile, 1901; formerly on the faculty of his alma mater; specialist certified by the American Board of Psychiatry and Neurology; member of the Southern Psychiatric Association, of which he was past president, and the American Psychiatric Association; past president of the Medical Association of the State of Alabama and the Southern Neuropsychiatric Association; an organizer, past president, and secretary of the Alabama Society for Mental Hygiene; for many years superintendent of the Alabama Insane Hospital, which includes the Bryce Hospital and the Partlow State School in Tuscaloosa and the Searcy Hospital in Mount Vernon; awarded an honorary LL.D. by the University of Alabama in 1921; died July 7, aged 76, of pulmonary emphysema.

Whalen, John Francis ⊕ Altadena, Calif.; born in New Brunswick, N. J., Nov. 18, 1900; Jefferson Medical College of Philadelphia, 1927; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; formerly instructor in medicine at the University of Southern California School of Medicine; served as secretary, president, and chairman of the executive board of the Pasadena Medical Society; past president of the Pasadena Branch of the Los Angeles County Medical Society; affiliated with Huntington Memorial Hospital and St. Luke Hospital, where he was chairman of the board of directors and president of the staff; for many years on the staff of the Los Angeles County General Hospital; died July 3, aged 52, of coronary thrombosis and myocardial infarction.

Smith, H. Mason ⊕ Tampa, Fla.; born in Douglasville, Ga., May 10, 1884; University of Georgia Medical Department, Augusta, 1908; specialist certified by the American Board of Psychiatry and Neurology; member of the Southern Psychiatric Association and the American Psychiatric Association; fellow of the American College of Physicians; past president of the Florida Medical Association and the Florida State Board of Health; served during World War I; at one time superintendent of the Florida Hospital for the Insane in Chattahoochee; on the courtesy staffs of St. Joseph's and Tampa Municipal hospitals; consultant, Veterans Administration; neuropsychiatrist, Atlantic Coast Line Railway; died in St. Joseph's Hospital June 16, aged 69.

Roll, Lewis Robert ⊕ Seattle; born in Frankfort, Ind., April 20, 1910; University of Chicago School of Medicine, 1941; member of the American Trudeau Society; interned at Virginia Mason Hospital and Riverton Hospital for Chest Diseases; served a residency at the University Hospital in Ann Arbor, Mich.; clinical instructor in medicine at the University of Washington Medical School; in 1945-1946 affiliated with the Washington State Board of Health; for a short time director of Aldercrest Sanatorium in Snohomish; chief of medical service, Firland Sanatorium; died in the Swedish Hospital June 20, aged 43, of cerebral hemorrhage and basilar skull fracture as the result of a fall.

Stevenson, Frank Earl ⊕ Cincinnati; born in Circleville, Ohio, in 1895; University of Cincinnati College of Medicine, 1923; associate professor of pediatrics at his alma mater; during World War I in Chemical Warfare Service Arsenal in Maryland; specialist certified by the American Board of Pediatrics; member of the Cincinnati Academy of Medicine and the American Association for the Advancement of Science; affiliated with Children's and Cincinnati General hospitals; contributor of articles on infectious diseases to Cyclopedia of Medicine, Musser's Textbook of Internal Medicine, and Mitchell-Nelson Textbook of Pediatrics; died in Christian R. Holmes Hospital July 9, aged 57.

Warinner, Algernon Storrs ⊕ Hempstead, N. Y.; born in Richmond, Va., in 1894; Johns Hopkins University School of Medicine, Baltimore, 1920; fellow of the American College of Surgeons; chief of surgery, Mercy Hospital, Rockville Center; director of surgery, Meadowbrook Hospital in Hempstead; consultant, South Nassau Community Hospital in Rockville Center, North Country Community Hospital in Glen Cove, Nassau Hospital in Mineola, Southside Hospital in Bay Shore, and the Mather Memorial Hospital in Port Jefferson; died July 11, aged 58, of carcinoma of the left lung.

Bernstein, Solon S. ⊕ New York City; born in New York City Oct. 19, 1896; Columbia University College of Physicians and Surgeons, New York, 1920; specialist certified by the American Board of Internal Medicine; member of the American Heart Association, American Association for the Advancement of Science, National Tuberculosis Association, and the American Psychosomatic Society; served on the faculty of his alma mater; affiliated with Mount Sinai, Sydenham, Riverside, and Beth Israel hospitals; editor in chief, *Journal of the Mount Sinai Hospital;* died July 10, aged 56.

Buchanan, Albert S. ⊕ Prescott, Ark.; born in Prescott in 1881; University of Arkansas School of Medicine, Little Rock, 1905; past president of the Arkansas State Medical Society and the Sixth Councilor District Medical Society; past president and secretary-treasurer of the Arkansas Board of Medical Examiners; served as a member of the state board of health; member of the American Academy of General Practice; past president of the Nevada County Medical Society; on the staff of the Cora Donnell Hospital; died July 4, aged 72, of carcinoma of the left lung.

Bland, Leonard Frederick ⊕ Dallas, Texas; Memphis (Tenn.) Hospital Medical College, 1904; died in Baylor University Hospital May 10, aged 75, of uremia, prostatitis, and tuberculosis.

Bradford, Duke Constantine ⊕ Birmingham, Ala.; Birmingham Medical College, 1914; served during World War II; died in Walter Reed Army Hospital, Washington, D. C., April 11, aged 51, of carcinoma.

Briggs, Leroy Hewitt ⊕ San Francisco; University of California Medical School, San Francisco, 1908; William Watt Kerr professor of clinical medicine emeritus at his alma mater; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; chief physician, San Francisco Hospital; consulting physician, University of California, Franklin, French, and U. S. Marine hospitals; died in Notre Dame Hospital June 29, aged 70, of carcinoma of the rectum.

Browning, Zack Clark, Augusta, Ga.; University of Georgia School of Medicine, Augusta, 1946; resident, University Hospital; served during World War II; died April 30, aged 37, of coronary occlusion and pulmonary edema.

Clarke, Clayton Reynolds ⊕ Fort Worth, Texas; University of Buffalo School of Medicine, 1897; member of the Medical Society of the State of New York; for many years practiced in Ransomville, N. Y.; died June 20, aged 77, of a cerebral vascular accident and arteriosclerosis.

Costello, Bernard Edward ⊕ Vandling, Pa.; Jefferson Medical College of Philadelphia, 1914; died June 21, aged 74, of arteriosclerosis.

Dichek, Maurice ⊕ New York City; Middlesex University School of Medicine, Waltham, Mass., 1943; affiliated with Hospital for Joint Diseases and Medical Arts Center Hospital; died recently aged 34, of myocardial infarction.

Fernandes, Philip Mathias, Los Angeles; Howard University College of Medicine, Washington, D. C., 1935; died June 30, aged 47.

⊕ Indicates Member of the American Medical Association.

Ferringer, John Edward ⊕ Stoneboro, Pa.; Medical Department of the Western University of Pennsylvania, Pittsburgh, 1908; for many years president of the board of health of Stoneboro; examining school physician; on the staff of Grove City (Pa.) Hospital and Mercer Cottage Hospital in Mercer; died in Franklin (Pa.) City Hospital June 20, aged 74, of cirrhosis of the liver.

Fink, Harry Myer, Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1900; served during World War I; affiliated with Montefiore Hospital, where he died June 26, aged 74, of arteriosclerotic heart disease and Stokes-Adams syndrome.

Ford, Charles ⊕ Hillsboro, Ill.; Barnes Medical College, St. Louis, 1904; specialist certified by the American Board of Radiology; member of the Radiological Society of North America and the American College of Radiology; died in Hillsboro Hospital April 22, aged 70, of a cerebral vascular accident.

Frandsen, Charles ⊕ Omaha; University of Nebraska College of Medicine, Omaha, 1918; associate in internal medicine at his alma mater; served during World War I; affiliated with Nebraska Methodist Hospital, Creighton Memorial St. Joseph's Hospital, and Bishop Clarkson Memorial Hospital; president of the staff of Immanuel Hospital; died June 20, aged 64, of coronary thrombosis.

Fulep, Joseph ⊕ Dannemora, N. Y.; Magyar Királyi Pázmány Petrus Tudományegyetem Orvosi Fakultasa, Budapest, Hungary, 1923; supervising psychiatrist at the Dannemora State Hospital; died in Physicians Hospital, Plattsburgh, May 24, aged 58, of coronary thrombosis.

Glick, Meyer Joseph ⊕ Miami Beach, Fla.; Detroit College of Medicine and Surgery, 1925; died May 24, aged 59.

Graham, Fred Wilson ⊕ Morris, Ill.; Chicago Medical School, 1923; on the staff of the Morris Hospital; died July 14, aged 69, of cerebral hemorrhage.

Guice, Charles Lee ⊕ Gadsden, Ala.; Medical Department of Grant University, Chattanooga, Tenn., 1893; past president of the Etowah County Medical Society; member of the board of directors of the American National Bank; affiliated with Holy Name of Jesus Hospital, where he died July 8, aged 83, of arteriosclerotic heart disease and diabetes mellitus.

Herrmann, Ross Edward ⊕ Bradford, Ill.; University of Illinois College of Medicine, Chicago, 1934; served during World War II; died April 21, aged 46, of coronary disease.

Howard, Elmer Ellsworth, San Antonio, Texas; (licensed in Mississippi in 1902 and Illinois in 1925); formerly practiced in Chicago; died June 13, aged 74, of cerebral hemorrhage and hypertension.

Hurley, Frank James ⊕ Bennington, Vt.; Albany (N. Y.) Medical College, 1905; fellow of the American College of Surgeons; past president of the Vermont State Board of Medical Registration and the Vermont State Medical Society; chief of staff at Putnam Memorial Hospital, where he died June 28, aged 70, of coronary thrombosis.

Jones, Leonidas Leroy ⊕ Portsmouth, Va.; University of Pennsylvania School of Medicine, Philadelphia, 1917; fellow of the American College of Surgeons; served during World War I; affiliated with Kings Daughters Hospital and the Maryview Hospital, where he died May 29, aged 60, of coronary thrombosis.

Keese, John Mumford, ⊕ Syracuse, N. Y.; Hering Medical College, Chicago, 1898; on the staff of the Syracuse General Hospital; died June 19, aged 80, of acute myocardial insufficiency.

Kuhn, Leo Cornelius ⊕ Decorah, Iowa; the Hahnemann Medical College and Hospital, Chicago, 1916; past president of the Winneshiek County Medical Society; member of the Radiological Society of North America, Iowa Heart Association, American Heart Association, and the Rock Island Railway Surgeons Association; served during World War I; died June 23, aged 64, of acute coronary occlusion.

Lemieu, Theodule Alfred ⊕ Lawrence, Mass.; Laval University Faculty of Medicine, Quebec, 1897; died in New England Medical Center, Boston, May 30, aged 80, of acute myocardial infarction.

McDonnell, John Joseph, Scranton, Pa.; Georgetown University School of Medicine, Washington, D. C., 1931; attending physician at Marywood College; affiliated with St. Mary's Hospital and Mercy Hospital, where he died June 19, aged 50.

Meister, Edward Frederick ⊕ Buffalo; University of Buffalo School of Medicine, 1913; affiliated with Buffalo General Hospital, Edward J. Meyer Hospital, and the Millard Fillmore Hospital, where he died June 7, aged 64, of hepatocellular carcinoma of the liver.

Merz, Adolph, St. Louis; Marion-Sims Beaumont Medical College, St. Louis, 1903; affiliated with Lutheran and Alexian Brothers hospitals; died in St. Anthony's Hospital June 29, aged 71, of uremia, following intestinal surgery.

Miller, John Floyd ⊕ Marion, N. C.; Medico-Chirurgical College of Philadelphia, 1906; county physician; on the staff of the Marion General Hospital; died in Baptist Hospital, Winston-Salem, June 2, aged 75, of ruptured aortic aneurysm.

Miller, John Johnston Jr. ⊕ San Francisco; Stanford University School of Medicine, San Francisco, 1929; associate clinical professor of pediatrics at his alma mater; specialist certified by the American Board of Pediatrics; member of the American Pediatric Society, American Academy of Pediatrics, and the American Public Health Association; served during World War II; affiliated with San Francisco and French hospitals; died June 13, aged 49, of carcinoma of the rectum.

Morison, Garnett Pierce ⊕ Charles Town, W. Va.; Chicago College of Medicine and Surgery, 1914; past president of the West Virginia Academy of Ophthalmology and Otolaryngology; served as president, secretary, and treasurer of the Eastern Panhandle Medical Society; veteran of World War I; for two terms mayor of Charles Town; formerly health officer of Jefferson County; on the staff of the Charles Town General Hospital, where he died June 27, aged 68, of a heart attack.

Murphy, Wilbur J., New York; Fordham University School of Medicine, New York, 1912; died in Misericordia Hospital July 3, aged 82, of cerebral hemorrhage.

O'Connor, Charles Mallon ⊕ Colonel U. S. Army, retired, Palo Alto, Calif.; University of Virginia Department of Medicine, Charlottesville, 1913; fellow of the American College of Surgeons; entered the medical corps of the U. S. Army in July, 1915 and retired May 31, 1947; served during World War II; fellow of the American College of Surgeons; died June 3, aged 63, of coronary thrombosis.

Olch, Benedict, Dayton, Ohio; Harvard Medical School, Boston, 1919; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; affiliated with Good Samaritan and St. Elizabeth hospitals; member of the board of directors and chief in medicine at Miami Valley Hospital; died June 27, aged 59, of coronary thrombosis.

Palfrey, Francis Winslow ⊕ Duxbury, Mass.; Harvard Medical School, Boston, 1902; an Associate Fellow of the American Medical Association; formerly on the faculty of his alma mater; served in France during World War I; affiliated with Massachusetts General and Boston City hospitals; died June 11, aged 76, of coronary thrombosis.

Pattajo, Christus Alexander, Belmont, Mass.; Harvard Medical School, Boston, 1911; for many years physician at the Suffolk Downs race track; served on the staff of the Massachusetts General Hospital in Boston; died June 11, aged 69.

Patton, Lewis Suddath ⊕ Athens, Ga.; Emory University School of Medicine, 1923; affiliated with Athens General and St. Mary's Hospital; died in Elberton June 23, aged 57, of injuries received in an automobile accident.

Pfisterer, Frank William, Milwaukee; Marquette University School of Medicine, Milwaukee, 1913; died in Columbia Hospital June 16, aged 65, of hypertension and arteriosclerotic heart disease.

Popovich, Theodore, Fayetteville, Ark; Columbia University College of Physicians and Surgeons, New York, 1924; served during World War II; affiliated with Veterans Administration; died in Veterans Administration Hospital May 27, aged 53, of bronchopneumonia and tracheal obstruction.

Priessman, Frank Albert ⊕ Keokuk, Iowa; Chicago College of Medicine and Surgery, 1913; served during World War I; affiliated with Graham and St. Joseph's hospitals; died May 13, aged 68, of carcinoma of the liver.

Purdy, Charles Humphrey ⊕ Jersey City, N. J.; Bellevue Hospital Medical College, New York, 1895; for many years affiliated with Christ Hospital and Jersey City Medical Center; died July 1, aged 85, of acute coronary occlusion.

Ranes, Annie R., Chicago; Illinois Medical College, Chicago, 1903; died June 22, aged 82, of chronic myocarditis.

Rau, Conrad Fred ⊕ Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1904; died May 3, aged 70.

Reimel, Clara, West Oak Lane, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1895; died June 30, aged 81.

Scantleton, John Martin ⊕ Sparta, Wis.; Northwestern University Medical School, Chicago, 1913; died in St. Mary's Hospital June 16, aged 63, of cerebral hemorrhage.

Schilling, Albert Henry ⊕ Mariemont, Ohio; University of Cincinnati College of Medicine, 1942; served during World War II; affiliated with Our Lady of Mercy Hospital; died June 23, aged 38, of pulmonary embolism.

Schmidt, Walter William ⊕ Cliffside Park, N. J.; University and Bellevue Hospital Medical College, New York, 1912; served during World War I; for many years member of the Cliffside Park Health Board; formerly member of the board of education; on the staff of the Englewood (N. J.) Hospital, where he died June 7, aged 62, of cardiac failure.

Scimeca, Anthony J., Kansas City, Mo.; St. Louis College of Physicians and Surgeons, 1922; died June 30, aged 55, of coronary disease.

Seedenburg, Jesse Peightal, Pittsburgh; Jefferson Medical College of Philadelphia, 1907; for many years medical examiner for the Equitable Life Assurance Company; affiliated with Pennhurst State School in Spring City; died in Phoenixville, Pa., July 1, aged 73, of cirrhosis of the liver.

Shea, John ⊕ Bridgeport, Conn.; College of Physicians and Surgeons, Baltimore, 1911; member of the founders group of the American Board of Surgery; fellow of the American College of Surgeons; past president of the Fairfield County Medical Society; affiliated with the Bridgeport Hospital, where he died June 12, aged 67, of acute hemorrhagic pancreatitis.

Shukuris, Avraam Andronious ⊕ New York City; Columbia University College of Physicians and Surgeons, New York, 1921; fellow of the American College of Surgeons; affiliated with French and Harlem hospitals; died June 18, aged 60, of metastatic carcinoma of the brain.

Singer, Erich ⊕ New York City; Medizinische Fakultät der Universität, Vienna, Austria, 1924; on the staff of the Mount Sinai Hospital; died in Jewish Memorial Hospital May 11, aged 53, of acute coronary thrombosis.

Smith, Benjamin T. ⊕ Carnesville, Ga.; Atlanta College of Physicians and Surgeons, 1906; died in Milledgeville May 28, aged 80, of a cerebrovascular accident, hypertension, and arteriosclerosis.

Smith, Earle Edwin, Bardwell, Ky.; University of Tennessee College of Medicine, Memphis, 1914; died May 13, aged 64, of coronary occlusion.

Smith, James Henderson ⊕ Richmond, Va.; University College of Medicine, Richmond, 1910; professor of clinical medicine at the Medical College of Virginia; specialist certified by the American Board of Internal Medicine; member of the American Clinical and Climatological Association; past president of the Richmond Academy of Medicine; served during World War I; on the staff of St. Luke's Hospital, where he died June 4, aged 70, of coronary occlusion.

Snook, Lee Owen Jr. ⊕ Wesley, Iowa; Northwestern University Medical School, Chicago, 1940; president of the Kossuth County Medical Society; president of the local school board; charter member of the library board; past president of the Lions Club; died in St. Ann's Hospital, Algona, June 3, aged 42, of acute nephritis and hypertension.

Snyder, Simon Barron ⊕ Hazard, Ky.; Hospital College of Medicine, Louisville, 1897; affiliated with Hurst-Snyder Hospital, where he died May 1, aged 84, of coronary thrombosis.

Stephens, Anna Overholt ⊕ State College, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1936; affiliated with Pennsylvania State College; died June 29, aged 49, of a cerebrovascular accident.

Sternberg, Joseph D. ⊕ Portland, Ore.; Rush Medical College, Chicago, 1901; affiliated with St. Vincent's Hospital; died June 17, aged 75, of coronary thrombosis.

Stouffer, Clyde Bruce, Ann Arbor, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1913; died in St. Joseph's Mercy Hospital June 12, aged 75, of a hip fracture suffered in a fall.

Troutman, George Christian, Exeter Township, Douglassville R.D., Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1899; died in Wernersville (Pa.) State Hospital June 19, aged 75, of hypostatic pneumonia and arteriosclerosis.

Urbanski, Walter Joseph, Cleveland; Ohio State University College of Medicine, Columbus, 1938; served during World War II; affiliated with St. Alexis Hospital, where he died July 8, aged 45, of carcinoma of the rectum.

Walker, Francis Milton, Rochester, N. Y.; College of Physicians and Surgeons, Baltimore, 1906; died July 1, aged 72, of coronary occlusion.

Wallace, John C., Arlington, Va.; Medical Department of Tulane University of Louisiana, New Orleans, 1899; died June 30, aged 78.

Wallace, Paul Bartlett, Montrose, Colo.; Hering Medical College, Chicago, Homeopathic, 1902; died June 26, aged 74, of cardiac failure and right hemiplegia.

Wells, Frank Happersett ⊕ West Chester, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1913; served during World War I; affiliated with Chester County Hospital, where he died June 29, aged 67, of carcinoma of the rectum.

Whiteside, Jesse DuBois ⊕ Aberdeen, S. D.; Northwestern University Medical School, Chicago, 1906; fellow of the American College of Surgeons; served during World War I; affiliated with St. Luke's Hospital, where he died May 18, aged 74, of arteriosclerosis.

Wilson, William Franklin ⊕ Lake City, Minn.; Chicago Medical College, 1891; an Associate Fellow of the American Medical Association; for many years secretary-treasurer of the Wabasha County Medical Society; on the staff of Lake City Municipal Hospital; died May 28, aged 88, of coronary occlusion.

Wolk, Melvin ⊕ New York City; University and Bellevue Hospital Medical College, New York, 1907; adjunct professor of gynecology and obstetrics at the New York Polyclinic Medical School and Hospital, where he died June 5, aged 75.

Young, William B., Cincinnati; Medical College of Ohio, Cincinnati, 1894; died May 22, aged 83.

Zabokrtsky, Joseph ⊕ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901; fellow of the American College of Surgeons; served during World War I; for many years affiliated with the Hospital of St. Anthony de Padua, where he died July 12, aged 79, of carcinoma of the stomach.

Zimmerman, Albert Sidney ⊕ Montgomery, Ala.; University of the South Medical Department, Sewanee, Tenn., 1897; served as secretary-treasurer of Lauderdale County Medical Society; formerly health officer of Lauderdale County; died in Prattville May 15, aged 83, of cerebral hemorrhage.

FOREIGN LETTERS

LONDON

Organized Clinical Research.—The setting up of a clinical research board is one of the major recommendations contained in a recently published White Paper entitled "Clinical Research in Relation to the National Health Service." Under the National Health Service Acts the Minister of Health and the Secretary of State for Scotland are given powers to undertake research or to help others to do so. Direct powers to undertake research are also conferred on the boards of governors of teaching hospitals, regional hospital boards, and hospital management committees. Independently of these acts and dating back to powers granted under the Ministry of Health Act, 1919, the Medical Research Council has the duty within the United Kingdom, and the powers elsewhere, to promote medical research of all kinds, including research that requires direct access to patients. In order to coordinate these different provisions, a joint committee of the Medical Research Council and the Standing Medical Advisory Committee of the Ministry of Health was appointed, and it is the report of this committee that has been published as a White Paper.

A clinical research board was said to be necessary for the following reasons: (*a*) to advise on the spending of funds provided by the government; (*b*) to deal with investigations and field researches that extend beyond regional boundaries or that are beyond the resources or outside the scope of local bodies; (*c*) to encourage research in fields not hitherto adequately covered; (*d*) to collect, collate, and distribute information to help in reducing the time lag between discoveries and their application and to avoid unintentional reduplication of investigations; and (*e*) to supervise an organization providing careers in clinical research in association with the National Health Service. The board would be essentially concerned with promoting clinical research on a national basis, and its scope would range from "problems of basic clinical research to broad investigations of the applicability of a remedy or the prevalence of an illness." The board would function by giving research grants and setting up clinical research units. It is recommended that the clinical research board would be appointed by, and would be responsible to, the Medical Research Council. It would have 10 members, 5 chosen from a panel prepared by the health departments and 5 chosen from a panel prepared by the Medical Research Council. The chairman would be chosen by the Medical Research Council. "The aim should be to form a well-balanced team of persons experienced in the clinical and research fields." The estimated additional funds required annually for the work of the board are £50,000 in the first year, increasing to £250,000 in the third and fourth years.

In addition, it is thought that there should be decentralized research at the level of regional hospital boards, boards of governors, and hospital management committees financed from National Health Service funds or from local resources. Such "decentralized research" is considered necessary (*a*) to foster the research spirit in medicine that is demanded by the highest standards of clinical practice and (*b*) to facilitate the discovery and encouragement of local talent. A research committee should be set up by each hospital board, after consultation and in agreement with the associated university or medical school, to advise on the spending of the research budget and the appointment of research workers. Yearly reports should be submitted by hospital boards to the Ministry of Health for transmission to the Clinical Research Board.

The whole problem of careers in clinical research is considered in detail. The view is expressed that "any scheme for careers in clinical research which does not provide terms and conditions as attractive as the best in medicine is unlikely to maintain in its service the requisite quota of able men." Therefore, "any scheme for clinical research workers which puts them in a position inferior to practising colleagues would be certain to arouse resentment." The "inescapable conclusion" is that clinical research careers must be equated with careers in the National Health Service, i. e., they must confer the same status, carry the same salary and superannuation rights, and entitle the holder to the same distinction awards. This would ensure complete freedom of interchange of staff and allow a man to revert from clinical research to a purely clinical appointment should he wish to do so, without any loss of status, salary, or superannuation rights. Further, any criteria for determining the training of consultants and specialists should recognize research and clinical experience in a field of clinical research as appropriate training for according full consultant or specialist status in that particular field."

These proposals have been "welcomed and accepted, subject to detailed consideration of their practical application" by the responsible ministers, as well as by the Chancellor of the Exchequer, and the latter is "ready to agree in principle to reasonable additional financial provision from the Exchequer, on the lines suggested in the report, as the work develops."

Prescribability of Proprietaries.—Almost coincidentally with the fifth anniversary of the inauguration of the National Health Service, the first steps have been taken in the Ministry of Health's campaign to reduce the national drug bill by proscribing proprietary medicine. The build-up of this offensive goes back to 1949, when there was established a joint committee on prescribing of the Central and Scottish Health Services Councils to "consider the report from time to time whether it is desirable and practicable to restrict or discourage the prescribing by practitioners giving general medical services under the National Health Service Acts of 1946 and 1947, of (1) drugs and medicines of doubtful value or of unethical character; (2) unnecessarily expensive brands of standard drugs." In June, 1950, the committee presented an interim report, the gist of which was that proprietary preparations could conveniently be arranged in six categories: (1) new drugs of proved value not yet standard; (2) proprietary brands of standard drugs, singly or in combination; (3) standard preparations, and new remedies of proved value, in elegant form or vehicle; (4) qualitative and/or quantitative modifications in the composition or combination of standard preparations, or new remedies of proved value, that are not accepted as therapeutically superior to preparations included either alone or in combination in the British Pharmacopoeia, the British Pharmaceutical Codex, or the National Formulary; (5) preparations not in the British Pharmacopoeia, British Pharmaceutical Codex, or National Formulary, which in the committee's view have not been proved of therapeutic value; and (6) preparations that are a combination of (4) and (5). The committee recommended that proprietary preparations in category 1 should be "freely prescribable," and that those in categories 2, 3, and 4 should be prescribable provided they were not advertised to the public and provided satisfactory arrangements for pricing could be made between the health departments and the manufacturers. Categories 5 and 6 were dealt with as follows: "Apart from preparations in categories (5) and (6) . . . we have no reason for suggesting on medical grounds that these proprietary preparations should not be freely prescribable in the National Health Service except when advertised to the public."

This report having been accepted, the committee then proceeded to classify proprietary preparations according to the six categories. During the last 2½ years, the committee has reviewed some 5,000 preparations, and 800 of these have been placed in categories 1, 5, or 6. A list of these 800 preparations has been sent to every physician taking part in the National Health Service. This list shows that 150 preparations have been placed in category 1, and 650 in categories 5 and 6. It is stated that preparations not shown in this list may be assumed to fall into categories 2, 3, and 4, until supplementary lists are issued. The bulk of the preparations placed in categories 5 and

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

6 consist of polyglandular oral preparations, enzyme preparations, such as diastase and pepsin, some metallic colloidal preparations, oral vaccines, chlorophyll tablets, and epinephrine (Adrenalin) cream.

In a covering letter, the chief medical officer of the Ministry of Health asks practitioners not to prescribe preparations in categories 5 and 6 and "only to prescribe preparations not included in the enclosed lists after you have ascertained the cost and compared it with that of identical or similar standard preparations and not to prescribe preparations of which the price is not readily and conveniently ascertainable." He adds: "Obviously what I have said is without prejudice to your right to prescribe whatever you think necessary in any individual case but a general practitioner may, of course, be called on to justify the cost of his prescribing to his colleagues on the Local Medical Committee." Such veiled threats are anathema to a liberal profession, but they seem to be the inevitable accompaniment of a government-controlled service. On the other hand, it is only fair to point out that few, if any, of the banned preparations are any loss to treatment. Even the Association of British Pharmaceutical Industry can find no real grounds for criticism of the classification on this account.

PARIS

Tetanus in France.—In a lecture before the National Academy of Surgery, M. J. Chavannaz drew attention to the presence of tetanus in France in time of peace and to the existence of certain dangerous areas, especially Nanterre. On the other hand, railway workshops and the great metallurgic plants of Creusot and Northern France are quite unaffected. An inquiry among physicians of the Gironde Département as early as 1932 allowed the author to gather 50 unpublished cases of tetanus, most of them fatal. These morbidity and mortality rates occurred in spite of many precautions and systematic administration of tetanus toxoid in cases of wounds. The author pointed out certain other areas in which tetanus has occurred in the Dordogne Département since 1932 and in Normandy. Prof. C. B. Griffiths and Mrs. Groselier drew attention to other regions, the valleys of the Allier and Dore rivers and also in Meurthe-et-moselle. According to Professor Galy, tetanus is also frequent in certain regions of Ardèche. Chavannaz proposed drawing a detailed map of regions in which tetanus occurs often in France in order to facilitate prevention of this disease.

A New Antituberculosis Agent.—A new substance synthesized by the chemist H. Passedouet is the isonicotinyl hydrazone of glucuronolactone. Biological and clinical experiments were carried out by Prof. G. Brouet and Drs. B. N. Halpern, J. Marche, and J. Mallet, at the Lariboisière Hospital and the Broussais Hospital.

Experiments with this new substance on mice revealed that it is one-fifth as toxic as isoniazid; the LD_{50} dose is 30 mg. per 20 gm. of body weight, whereas for isoniazid it is 4 to 5 mg. per 20 gm. of body weight. Administration of this new substance to young rats for a long period revealed that it stimulates appetite and has a eutrophic action. Studies on dogs with the large intravenous dose of 30 mg. per kilogram of body weight revealed that this drug does not modify the effects of electrical excitation of the sympathetic nerves. Studies of metabolism in the dog showed that, following intravenous administration of the drug, it is eliminated rapidly; 400 mg. were eliminated within three hours.

Bacteriostatic action of this substance in comparison to that of isoniazid and streptomycin in vitro for 28 different strains of Mycobacterium tuberculosis was studied. Experiments showed that, in an equal weight, the action of the new substance is equivalent to that of isoniazid. Investigations on the guinea pig and rabbit revealed in the rabbit a normal pulmonary radiographic image during treatment; 60 days later autopsy showed the absence of lesions, or if any were present, they were very small. Results were identical with those obtained with an equal amount of isoniazid. The authors conclude that, in animals, this new drug exerts a potent therapeutic effect on experimental tuberculous infection induced by various strains of the tubercle bacillus injected subcutaneously as well as intravenously. It provides immediate protection for most of the animals treated and slows the evolution of existing tuberculosis.

Clinical studies were made on 36 patients (15 men and 21 women) who were observed for four months. The drug was given in the daily dose of 1.2 to 1.6 gm. Tolerance was remarkable: no renal, hepatic, or neurotonic disorders were observed. Gastric pain and nausea were reported with a dose of 2 gm. The action of the drug on the general condition and on the temperature is remarkable. More surprising were bacteriological results; within the first week of treatment the sputum became negative; roentgenologic results were good in 25 cases of recent infection, of which 19 were the ulceronodular form. In 10 cases regression of cavities and in 7 their disappearance was observed. Two failures are reported. On the contrary, in long-standing tuberculosis, no improvement was noted except in three patients with old, but limited lesions, in whom bacteriological improvement was observed.

Radioactive Iodine in Exophthalmic Goiter.—Prof. Gilbert Dreyfus and Drs. M. Zara, Ambrosino, Triantaphyllides, and J. Ginzburger have employed radioactive iodine (I^{131}) in treatment of 100 cases of exophthalmic goiter (Basedow's disease) over a two year period in La Pitié Hospital. The principal indications for this treatment are recurrence of thyroiditis following surgical treatment, thyroiditis that is not amenable to the usual medical treatment, forms associated with progressive tuberculosis, and the presence of psychosis that contraindicates surgical treatment. Radioactive iodine has also been used when, on social or professional grounds, the patient was unable to undergo treatment extending over many months. The authors include among contraindications saturation of the thyroid with iodine following treatment with iodine even a long time previously. They do not use this form of treatment in very young children or during pregnancy, as the fetal thyroid is receptive to the radioactive material from the third month of gestation.

The method of treatment is simple. The patient drinks one glass of water containing the radioactive iodine, and the hyperactive thyroid cells pick up their own destructive agent. The dose depends on the rate of uptake in the individual patient. Biological success is obtained in 30% of normal subjects and in between 20 and 70% of persons with exophthalmic goiter. The doses of radioactive iodine required for the cure vary from 3 to 30 mc. According to the authors, these doses are proportional to the degree of hyperthyroidism; in severe cases 15 to 25 mc. are required, in moderate cases 10 to 15 mc., and in mild cases 5 to 10 mc. On the other hand, doses are proportional to the volume of the thyroid gland and inversely proportional to the age of the patient. Aged patients require smaller doses than young persons. Total doses were divided into three to five individual doses for severe cases, into two to three doses in moderate cases, and into one to two doses in mild cases.

In a series of 62 patients, and after an eight month period of observation, the authors noted the following results: There were 23 complete recoveries with disappearance of clinical signs of thyroid toxicity and normalization of the radioactive iodine uptake curve, and 23 apparent recoveries, with disappearance of clinical signs and atypical uptake curves. Maintenance therapy is necessary in order to prevent relapse. In 13 cases there was an incomplete recovery, in 1 case failure, and in 2 cases the patients were lost to observation. The authors emphasize that the older the patients, the better the results obtained. The time at which the action of the drug occurs is variable; an immediate improvement may be noted within a few days of administration of the first dose, with slowing of the pulse and weight increase. The improvement may also be delayed, and there may even be general aggravation of symptoms. As a rule, improvement is evident by the end of the first month following treatment. The authors believe that now it should be possible to cure exophthalmic goiter in less than six months. A quicker recovery or doses given at too short intervals may lead to myxedema, or to edematous exophthalmos. The authors also presented a woman who had had severe asystolia associated with exophthalmic goiter. A complete cure was obtained with radioactive iodine.

CORRESPONDENCE

HOBBIES

To the Editor:—I like that engaging new feature "The Leisure Corner," which I came across for the first time in THE JOURNAL of July 4. Because the column so aroused my interest in spare time pursuits, I shall look forward to reading future pieces.

The benefits of philately as a hobby were demonstrated July 11 to 27 at the Cleveland Health Museum during the Third National Medical Stamp Exhibit, sponsored by the museum and the Garfield-Perry Stamp Club of Cleveland. This exhibit featured stamps that are connected with medicine through their designs or reason for issue, together with pertinent background information. The extent of the background material depended on how much research each exhibitor could, or would, lavish on his hobby. The entries of Mrs. R. B. Leggett, Houston, Texas, were accorded honorable mention. Prior to the exhibition, her physician wrote that Mrs. Leggett has been bedridden for years with atrophic arthritis, and he added: "Did you know under what trying circumstances she has prepared for her exhibit, you would appreciate how great has been the effort." In a notation on her entry blank, Mrs. Leggett wrote: "Stamp-collecting is my greatest therapy." Three men, all physicians, attained top honors. The comprehensive album pages of A. B. Bruner, M.D., Cleveland, won a gold cup and first-prize award certificate. The entry of Maurice J. Strauss, M.D., New Haven, Conn., placed second, and that of C. S. Hitchins, M.D., also of New Haven, was third.

We may conclude that the rewards of the philatelist are varied. To the physician, stamp-collecting gives a good feeling of individuality and relaxation, plus an occasional award to bolster a sense of accomplishment and recognition. To the shut-in, philately even has a therapeutic value. I feel confident that "The Leisure Corner" will suggest other thought-provoking and, let us hope, action-provoking outside interests.

OPTIC NEURITIS

To the Editor:—The correspondence of Martin M. Fisher, M.D., in THE JOURNAL, June 13, 1953, page 628, with reference to bilateral optic neuritis following enormous doses of chloramphenicol was carefully read by those who reported the case originally (Lasky, M. A.; Pincus, M. H., and Katlan, N. R.: *J. A. M. A.* **151**:1401 [April 18] 1953). The references mentioned and numerous others were read by us previously. The reports in the literature concerning the ophthalmologic findings associated with bacterial endocarditis describe two types: bilateral papilledema (in which the vision remains normal for a long time) and embolic phenomenon (unilateral optic neuritis, with unilateral loss of vision). The case we reported was that of rapid bilateral loss of vision. The edema of the nerve heads was not that of papilledema as the loss of vision was extremely rapid and the edema was slight and nonprogressive. That the loss of vision was embolic is also extremely unlikely, since embolism would have had to occur both simultaneously and bilaterally. In addition, this patient had been over his attack of bacterial endocarditis for several weeks when the ophthalmologic findings became manifest. For these reasons it is our belief that the case presented was one of toxic bilateral optic neuritis caused not by the bacterial endocarditis but by the large doses of the drug the patient had consumed.

TOO MUCH ROUTINE CARE

To the Editor:—After 30 years of obstetric experience, I sometimes think patients are subjected to too much routine study and treatment. Perhaps we have swung too far, therapeutically, from supporting patients in their natural functions and physiological reactions. The multiplicity of scientific articles that are simply statistical, often with the lack of perspective that term implies, seems to be in part the basis for these practices, which too often are put into effect en masse with little respect for individual reactions. Aspects of routine postpartum care in lying-in hospitals, such as (1) excessively early ambulation when involution is just beginning, (2) involution of the breasts too quickly (and distortion of normal hormonal balance) by the administration of hormones when simple supportive measures, including sufficient fluids, give better results, and (3) unnecessary treatments of the perineal wound, which needs nothing more than simple cleansing, are glaring examples. A recent editorial, "The Vaginal Douche—A Gynecologic Anachronism," (S. L. Israel: *Obst. & Gynec.* [May] 1953) is especially apropos. It presents the simple understanding of basic physiology from which, I believe, we should not be diverted by the complexities of modern medicine.

MILKER'S NODULES

To the Editor:—After noting Dr. Green's (*J. A. M. A.* **152**:757 [June 20] 1953) and Dr. Lane's (*J. A. M. A.* **152**:1067 [July 11] 1953) letters, and also for statistical purposes, I would like to add another published case of milker's nodules in New England (Ronchese, F.: Occupational Marks, New York, Grune & Stratton, 1948, p. 162 [fig. 150]). These were seen on a farm worker in July, 1941. Site, clinical appearance, and histopathology contributed to the diagnosis. This is the only case I have seen in 25 years of practice in Rhode Island. The rarity undoubtedly is due to the milking machine having replaced manual labor on many farms. For this reason, milker's nodules are of little value as marks of the trade. A warty lesion on a farmer is not necessarily a milker's nodule. With uncertain bacteriological and histological features, I am inclined to rely on the location (contact) and the purple-red base for a fair clinical diagnosis.

NOCTURNAL ENURESIS

To the Editor:—In an article in THE JOURNAL (**152**:381 [May 30] 1953), T. V. Geppert reports favorable results in treating a group of patients with chronic nocturnal enuresis. They were treated by being awakened by an automatic electric alarm immediately after the commencement of nocturnal urination. I proposed a similar type of therapy a few years ago in the *Swiss Medical Weekly* (*Schweiz. med. Wchnschr.* 78:361, 1948). The purpose of my procedure was the same: to condition the patients to awaken at the very moment of enuresis. Instead of an automatic electric alarm, which may disturb other persons too, a harmless but awakening electric current was used to condition the patient. This conditioning therapy allows the treatment of many children in the same room with individual conditioning stimuli.

Galactosemia: Unusual Cause of Neonatal Jaundice. D. Johns.—p. 575.

Cystinosis.—Cystinosis, a disturbance of protein metabolism that results in deposition of cystine in the tissues is reported in two siblings, a boy, 5 years and 9 months old, and a girl, 7 years and 3 months old. The clinical opinion was that these two children had a congenital anomaly of the urinary tract with resulting renal failure, secondary hyperplasia of the parathyroid glands, renal osteodystrophy, cardiac failure, and terminal uremia. The postmortem findings in the two cases were almost identical. Each child was markedly underdeveloped and poorly nourished. Microscopic examination revealed collections of crystalline material deposited in the tissues in the form of tiny irregular fragments, but some large crystals also were present. This material was soluble in hydrochloric acid and in ammonia. Chemical tests for cystine were positive. The cystine was most abundant in the spleen. The lymph nodes also contained a great deal of cystine. It was abundant in the cortex, both within the germinal centers and within the intervening tissue. Cystine was observed in the liver, thyroid, intestinal mucosa, lungs, in adrenals, pancreas, and testicles. Postmortem diagnosis was cystinosis, with nephrosclerosis, cardiac hypertrophy, passive hyperemia of the lungs, liver and spleen, hyperplasia of the parathyroids, uremic pericarditis, and uremic enterocolitis as secondary lesions. Animal experiments showed that the deposits in the tissues are not the result of disturbed renal excretion of cystine. The mechanism of the intractable rickets that accompanies cystinosis is also obscure. Both of the authors' patients had acidosis and hypophosphatemia before there was evidence of renal failure. The presence of early acidosis is fairly convincing evidence that the cystinosis may from the very beginning be combined with acidosis, but that does not provide any explanation as to the genesis of the acidosis. The renal lesions are also unexplained. Cystinosis is probably not so rare as the only 18 previously recorded cases suggest. The authors' two cases are the first reported in the United States.

Periarteritis Nodosa.—The occurrence of periarteritis nodosa in a 9-year-old boy is reported. The diagnosis was established by biopsy during the 31st month of illness. The patient apparently recovered from the disease during a 55 day period of therapy with cortisone, vitamins, and acetylsalicylic acid. A total dose of 3.025 gm. of cortisone was given. The hormone was administered after penicillin, streptomycin, aureomycin, sulfonamides, and other measures had proved ineffective. The patient has been free of symptoms, and his physical, mental, and emotional development was progressing normally two years after withdrawal of the drug.

Fungistatic Activity of Parabens.—The overgrowth of fungi following the extended use of antibiotics has attracted wide attention. The use of esters of parahydroxybenzoic acid (the parabens) as effective, nontoxic fungistatic agents has been suggested and has met with some success in combating monilial overgrowth when combined with aureomycin. The studies described by Siegel were undertaken to clarify the fungistatic action of methyl and propyl paraben against the common dermatophytes, including those fungi with a tendency to multiply abnormally following the use of antibiotics. Sabouraud's dextrose broth (containing 1% peptone and 2% dextrose) at pH 5.7, autoclaved for 20 minutes at 15 lb., was used for

be used in the test. Methylparaben- .S.P., and a combination of four parts part of the latter, by weight, were used. ctiveness of the parabens in low concen- r very low toxicity and lack of interference otic action of aureomycin, penicillin, and neo- d make them of particular interest in future preparations.

Ser Sickness Following Oxytetracycline Therapy.—A 10-year-old girl was in good health until an upper respiratory infection developed with headache and fever. She was given oxytetracycline (Terramycin) and Empirin No. 1 compound (containing codeine phosphate, acetophenetidin, caffeine, and acetylsalicylic acid). Two days later, on Feb. 19, 1952, small, pink, pruritic, erythematous wheals appeared that enlarged to form giant serpigenous lesions with clearing in the center. These were distributed all over her body and were of the erythema multiforme type of urticaria. There was also severe angioedema of the eyes and the face. She exhibited cyanosis of the extremities and of the lips and ears. On Feb. 21, fever and anorexia were noted. Her pulse was 120 per minute and temperature 101 F. Urticaria and lymphadenophy were noted. On Feb. 23, she appeared seriously ill, and was hospitalized. She responded well to symptomatic treatment and was discharged from the hospital six days later. The authors believe that this is the first recorded case of this type of reaction to oxytetracycline.

*Significance of Solitary, Asymptomatic, Intrathoracic Coin Lesion. M. L. Shiney and P. A. Harris.—p. 213.

Significance of Intrathoracic Coin Lesions.—The term coin lesion is used to describe a roughly spherical, well-circumscribed intrathoracic nodule seen on roentgenographic examination. Such lesions may be solitary or may be accompanied by other evidence of pulmonary disease; they may be symptomatic or asymptomatic. The final diagnoses of 137 patients with solitary asymptomatic pulmonary coin lesions from five different series are reported. A total of 131 of these patients were subjected to exploratory thoracotomy. Twenty-nine, or 21.2%, were found to have bronchiogenic carcinoma and 2.9% sarcomas. Another 11.7% had premalignant lesions (hamartomas, chondromas, and adenomas). Thus a total of 35.8% of the patients were harboring malignant or potentially malignant lesions. Proved or suspected tuberculous lesions constituted another 27% of the cases. Pulmonary carcinoma has no definite roentgenographic pattern, and there is no criterion that will always enable the examiner to deduce the cause of a roentgenographic density. The presence of calcium in the lesion may be considered suggestive of a tuberculous or histoplasmic lesion or of a premalignant process such as a chondroma or dermoid cyst. Caution must be exercised in arriving at such a diagnosis, since calcification within a malignant lesion is not unknown. Cavitation occurs in both malignant and benign lesions. Only rarely do roentgen rays outline the shadow of the tumor itself. The density is usually representative of the atelectatic result of neoplastic growth. Where atelectasis exists, infection usually follows, and the administration of antibiotics may diminish roentgenographic evidence of the tumor but at the same time have no effect on the fundamental disease process. The decrease in size of a pulmonary shadow after administration of antibiotics must never be considered as proof that the pulmonary disease is infectious in origin. When malignant disease cannot be ruled out, an exploratory thoracotomy must be done. The percentage of patients subjected to undesirable surgery will be small, because some benign lesions, such as adenomas and chondromas, are premalignant and should be resected. Many more lesions are tuberculomas, and since they are often refractory to medical therapy, the consensus is that surgical excision is the treatment of choice. The surgical risk in exploratory thoracotomy is less than 1%.

Recent Advances in Cancer Diagnosis. R. M. Shushan.—p. 157.

Hexamethonium and Hydralazine in Diastolic Hypertension.—Hexamethonium chloride alone or combined with hydralazine was given a therapeutic trial in 30 patients between the ages of 27 and 67 with severe diastolic hypertension. The patients were treated on the wards and in the outpatient department of a large general hospital. The blood pressure of the patients varied from 170 mm. to more than 300 mm. Hg systolic and 100 to 180 mm. Hg diastolic. The commonest symptoms were headache, dizziness, visual difficulties, palpitation, and symptoms of congestive heart failure. The patients were given 250 mg. of hexamethonium, orally every six hours. If the blood pressure failed to decline or decreased only slightly and if toxic side-effects did not occur within one to three days, the dose was increased to 250 mg. every four hours, then to 500 mg. every six hours, then to 500 mg. every four hours. The maximal dose reached 1,750 mg. every four hours. When the dose of hexamethonium reached 750 to 1,000 mg. every four hours without a satisfactory blood pressure response, hydralazine (Apresoline) was added in doses of 25 mg. every six hours. This was increased up to 100 mg. every four hours if necessary. In 21 of the 30 patients there was at least an initial good response. In 6 of the 21 patients the blood pressure returned to hypertensive levels and they were classified as therapeutic failures despite adequate dosage of the drug. There were six other patients in whom blood pressure was not controlled, but these did not receive adequate doses. Fourteen patients had good symptomatic improvement and seven moderate symptomatic improvement. There was no evidence of significant change in the symptoms of the remaining nine patients. In all patients followed for more than four months blood pressure has returned to hypertensive levels despite continued therapy, but in some this may have been due to inadequate therapy. In some instances the addition of hydralazine effected a fall in blood pressure when hexamethonium alone failed to do so. Blood pressure reduction and symptomatic relief tended to occur simultaneously, but in some patients symptomatic relief occurred without a change in blood pressure. It appears that these drugs will have at least a temporary place in the management of hypertension, but optimal dosage and criteria for selection of patients are not yet entirely evident.

Collection, Preservation, and Transfusion of Platelets.—During the past three years studies were conducted on 83 patients who received a total of 216 platelet transfusions by three different methods: administration of polycythemic blood or plasma directly, with the use of multiple silicone-coated syringes; transfusion of blood or plasma from polycythemic donors, collected in and administered by plastic sets or silicone-coated glass bottles and plastic tubing, acid citrate dextrose solution, or 1% disodium salt of ethylenediamine tetraacetic acid (Sequestrene) being employed as anticoagulants; administration of concentrates of platelets, isolated by complete separation of plasma through low-speed centrifugation of whole blood collected by gravity in silicone-coated glassware and with Sequestrene disodium as the anticoagulant and resuspended with isotonic sodium chloride or other solution. Forty-five patients had idiopathic thrombocytopenic purpura, 33 "amegakaryocytic" secondary thrombocytopenic purpura, and 5 "hypersplenic" thrombocytopenic purpura. Together with studies in vivo, observations were made on the preservation of platelets in vitro, as indicated by their ability to correct the coagulation defect and the deficient clot retraction of human platelet-poor plasma. As judged by rate of survival of injected platelets, by their ability to correct the hemostatic defect of thrombocytopenic patients in vivo and the coagulation abnormality of platelet-poor plasma in vitro, the various recently developed methods for the transfusion of large numbers of platelets and for their separation and concentration were not equally effective. The best method of administration of platelets seems to be the direct transfusion of polycythemic blood with the use of multiple silicone-coated syringes. Slightly less effective is the administration of blood collected in completely plastic or silicone-coated sets, by means of acid citrate dextrose solution or the calcium complexing agent Sequestrene disodium as anticoagulant. Platelets separated and suspended in their own plasma or isolated by various procedures and resuspended in isotonic sodium chloride or other solution show markedly reduced survival times in vivo, but their favorable influence on the hemostatic mechanism and the bleeding manifestations of thrombocytopenic patients is still noticeable. The introduction of agents giving glass and metal the properties of nonwettable surfaces and of surface-active agents preventing irreversible agglutination of platelets has greatly favored the development of methods for the collection, separation, and administration of platelets. The survival rate of platelets administered directly as platelet-rich polycythemic blood into patients with secondary thrombocytopenic purpura is four or five days. It is drastically reduced when a transfusion reaction occurs; when acute, uncontrollable bleeding is present; in patients with pronounced splenomegaly; in patients with idiopathic thrombocytopenic purpura, especially of the acute type; and as a result of the development of platelet agglutinins in patients who have received multiple platelet transfusions. The last finding indicates a potentially significant limitation to the use of platelets transfusions in the treatment of thrombocytopenic states.

Adrenocortical Function in Anorexia Nervosa.—Adrenocortical function was studied in a 19-year-old girl with anorexia nervosa when the patient weighed 75 lb. (34.1 kg.) and again two months after partial lobotomy, when she weighed 110 lb. (50 kg.). The increase in weight was due to increased food intake, especially of carbohydrates. Blood eosinophil counts made before the surgical intervention and after it did not show significant difference. The intramuscular injection of 25 mg. of corticotropin (ACTH) before the lobotomy caused a decrease of 75% in the blood eosinophil count in four hours. Intramuscular injection of 0.01 mg. of epinephrine per kilogram of body weight resulted in a fall of 55% in the count in four hours. Measurements of 17-ketosteroid output some weeks before the operation yielded values of 2.6 mg. on the average per 24 hours, while values after the operation averaged 13.5 mg. per 24 hours. The fasting blood sugar level was between 81 and 98 mg. per 100 cc. before the operation and 95 mg. two months after the operation. Blood sugar levels after ingestion of 100 gm. of glucose were abnormally high before the operation; ingestion of 100 gm. of glucose after intramuscular injection of 25 mg. of corticotropin (ACTH) revealed an even more abnormal curve. Two months after the operation, at a time when the patient had eaten large amounts of sweets for some weeks, the glucose tolerance curve was observed to be normal. The urinary estrogen excretion was 99 mcg. per 24 hours two months after lobotomy. These data show that adrenocortical function and reactivity are not depressed in anorexia nervosa. Lobotomy in the patient reported caused clinical improvement; no increase in adrenocortical activity occurred with improvement.

•Excessive Intake of Vitamin A as Cause of Congenital Anomalies in Rat. S. Q. Cohlan.—p. 535.

Congenital Anomalies in Rats Following Excessive Vitamin A Intake.—In experimental studies of the effect of vitamin A during pregnancy, 150 female rats of the CF Wistar strain were fed the standard Rockland pellet diet and water. From the 2nd, 3rd, or 4th to the 16th day post coitus 100 of these rats were given 35,000 I.U. of vitamin A in 0.7 ml. of diluent via a stomach tube. The 50 remaining rats served as controls and were fed 0.7 ml. of diluent. Excessive intake of vitamin A during gestation resulted in a reduction in the number of litters carried to term. Of 50 control females, 44 produced litters with a total of 410 normal newborn, a successful pregnancy rate of 88%. Of 100 females in the experimental group, only 10 carried young to term, with a total of 74 offspring, a successful pregnancy rate of 10%. Of 74 offspring produced in these 10 litters, 34 had a gross anomaly of the skull and extrusion of the brain. In the control group no anomalies were noted in 410 offspring. Other anomalies noted in the experimental litters were macroglossia, harelip, cleft palate, and gross defects in eye development. Comparable cranial anomalies have been produced in mice by other teratogenic methods, such as hypoxia.

Mechanism of Action of Tissue Therapy.—The results of the author's experiments on rabbits revealed that placental grafts or injections of placental extracts cause changes in the neurohormonal relationships that resemble those produced by corticotropin (ACTH). This therapy has a stimulating action on the adrenal glucorticoid secretion; since it does not involve the hypophysis and differs from the action of corticotropin, the stimulation is of an adrenocortical nature. The results suggested also that besides Filatov's "biogenous stimulators" there are probably some growth substances in the placental tissue that enhance proliferation. Because this therapy causes a deficiency of ascorbic acid in the adrenal gland, concurrent administration of this vitamin is a good adjuvant. The author reports clinical results with this therapy in 50 patients, of whom 25 were treated with grafts alone. In the other 25 the grafts were followed immediately by intramuscular or intravenous injections of 1 gm. of ascorbic acid daily for 15 days. There was a rapid and definitive remission of the symptoms in patients with acute rheumatism treated with grafts alone or with the combined treatment. The patients with chronic rheumatism and anatomic osteoarticular alterations improved rapidly and markedly, but the symptoms reappeared 15 to 20 days later when the grafts were completely absorbed. The patients with hypertension and hypotension received no benefit from the treatment. Good results were obtained in patients with ulcerative wounds, but there was a relapse as soon as the grafts were completely absorbed. A greater sensitivity to other forms of therapy, even if they had failed in the past, was seen in all these patients after the treatment with placental tissue or placental extracts was terminated.

Placenta Praevia Accreta: Case. A. J. J. M. Lindner.—p. 1003.

Liver Extract in Cirrhosis of Liver.—A man, aged 36, with hepatic cirrhosis of several years' duration was incapacitated because of the severity of the disease. Treatment with vitamins A, C, and D, with yeast and with 3 gm. of methionine daily produced only slight improvement. He resumed his work for about seven weeks, but had to be hospitalized once more, when he was given intravenous injections of unpurified liver extract. On the 1st day he was given 1 cc. of the extract in 25 cc. of isotonic sodium chloride solution; on the 2nd day 3 cc. in 30 cc. of solution; on the 3rd and 4th days 5 cc. in 40 cc. of solution; and from the 5th to the 14th days 10 cc. daily in 50 cc. of isotonic sodium chloride solution. After that he was given the 10 cc. dose three times a week until a total of 224 cc. of the extract had been administered. This exhausted the supply for the time being. At follow-up visits the patient said that he felt well and was able to be up and about and do some work. The tests of the hepatic function showed great changes. When several months later a new supply of the liver extract became available, he was given another course of injections. After that he felt so much improved that he was able to work, and the liver function tests indicated objective improvement.

*Immunization Against Diphtheria: Booster Dose. J. H. Mason and M. Robinson.—p. 293.
Negative Cercarial Antigen Skin Tests in Proved Urinary Bilharziasis in Children. H. I. Lurie, B. De Meillon, N. Stoffberg and H. H. Eiselen.—p. 295.

Booster Dose in Immunization Against Diphtheria.—The need for a booster dose of prophylactic diphtheria toxoid cannot be overstressed if the circulating antitoxin is to be maintained at an adequate level. Children usually tolerate a 10 Lf to 25 Lf dose of formaldehyde-toxoid or of alum-precipitated toxoid, but the occasional adolescent or adult who is sensitive to toxoid or to bacillary protein contaminating the toxoid may react severely to even a small dose of purified toxoid. One of the authors had been immunizing Schick-positive student nurses with 25 Lf of dissolved diphtheria toxoid-antitoxin floccules adsorbed on aluminum phosphate followed in six weeks with 25 Lf of unadsorbed dissolved floccules. At the time of the Schick and Schick control tests, the nurses received 0.5 Lf of unadsorbed dissolved floccules intracutaneously for checking their sensitivity to this antigen. Those with no reaction received 25 Lf more subcutaneously as a booster dose, but this was not given to those with a pseudo Schick reaction and/or with a reaction to the unadsorbed dissolved floccules. An antitoxin assay was made in such persons 14 days later, and all had adequate amounts of circulating antibodies at this time. This suggested that 0.5 Lf of unadsorbed dissolved floccules had acted as a booster and gave hope that it would have a similar effect in persons with negative Schick reactions; if such is the case, no further immunization would be necessary. Tests were carried out in student nurses and in adult volunteers. There was a history of immunization dating back 1 to 14 years in approximately 50% of them. Blood was taken, and immediately afterwards Schick toxin, Schick control fluid (heated toxin), and 0.5 Lf of unadsorbed dissolved floccules were injected intracutaneously into separate sites in the forearms. A second sample of blood was taken 14 to 21 days later from those who had negative Schick reactions or who had shown a pseudo reaction or a reaction to the dissolved floccules on the fourth day. The antitoxin content of the serums was determined, and showed that 0.5 Lf of unadsorbed dissolved floccules is a satisfactory booster dose in persons with negative Schick reactions, pseudo reactions to the Schick and Schick control tests, and local reactions to the dissolved floccules, a total of 104 persons in all. It had no demonstrable boosting effect on the circulating antitoxin of nine adults with positive Schick reactions, two of whom were known to have been immunized in the past.

BOOK REVIEWS

Conferences on Drug Addiction among Adolescents. Conferences were held at New York Academy of Medicine on November 30, 1951, and March 13 and 14, 1952, and were sponsored by Committee on Public Health Relations of New York Academy of Medicine, with assistance of Josiah Macy Jr. Foundation. Cloth. $4. Pp. 320. Blakiston Company (division of Doubleday & Company, Inc.), 575 Madison Ave., New York 22, 1953.

This book is a verbatim account of a series of conferences sponsored by the Committee on Public Health Relations of the New York Academy of Medicine, with financial assistance of the Macy Foundation. The 52 participants included representatives from the judiciary, the police, the New York City administration, the New York State Department of Health, the U. S. Public Health Service, the U. S. Bureau of Narcotics, and pharmacologists, social scientists, and social workers. Drug addiction was regarded as a serious problem because more than 3,000 arrests had been made last year, which was five times the number in 1946. The situation was discussed in general terms, and then the conference turned to action being taken to remedy the situation and how this might be improved. Methods of handling addicts as well as methods of prevention through education were discussed in detail. This book need not be read by all doctors, but it will be of great value to the responsible officials of any community confronted with the problem of drug addiction among adolescents.

Handbuch der inneren Medizin. Begründet von L. Mohr und R. Staehelin. Herausgegeben von G. v. Bergmann, W. Frey und H. Schwiegk. Band III: Verdauungsorgane. Teil 1. Bearbeitet von A. Gigon, G. Katsch, M. Lüdin, und H. Pickert. Teil 2. Bearbeitet von W. Baumann, et al. Fourth edition. Cloth. 328 marks. Pp. 941, with 283 illustration; 1293, with 229 illustrations. Springer-Verlag, Reichpietschufer 20, (1) Berlin W. 35 (West-Berlin); Neuenheimer Landstrasse 24, Heidelberg; Göttingen, 1953.

The third volume of this book, revised and reedited by three well-known internists, covers diseases of the digestive tract and is published in two sections, the first containing 941 pages, the second, 1,293 pages. In the first part, pages 814 to 941 cover the literature on the subjects considered in the volume. In the second part, pages 1009 to 1116 cover the literature and the remaining 176 pages are devoted to name and subject indexes that cover both volumes. The work is, therefore, not a handbook in the American sense but is a well-documented system of medicine differing from most American books in that each subdivision, infectious diseases, for example, can be bought separately.

The first article covers diseases of the mucous membrane of the mouth and is written by Alfred Gigon, who also contributes the article on diseases of the salivary glands. Diseases of the esophagus are covered by Max Ludin and diseases of the stomach by Gerhardt Katsch and Heinz Pickert. The object of the work is obviously to cover all subjects in a systematic manner, for the clinical discussions are preceded by a survey of the anatomy and physiology, at times, of the embryology, topography, bacteriology, and pharmacology, and, sometimes, by a brief historical note. Most sections begin with a discussion of congenital anomalies and acquired deformities; then come types of inflammation due to different organisms; tumors; mechanical, thermic, and chemical injuries; functional disturbances; and miscellaneous conditions such as calculi, fistulas, cysts, and accessory and aberrant glands. This system also differs from the American system in the extensive discussion of technical diagnostic procedures applicable to the different systems and diseases.

The second part contains articles on diseases of the intestines by Norbert Henning and Walther Baumann, who also contribute the section on diseases of the peritoneum. Diseases of the pancreas are covered by G. Katsch and M. Gülzow. Diseases of the liver and biliary passages are discussed by K. Beckmann.

The quality of the articles is excellent; they are comprehensive, methodical, and written in clear German, and the documentation contains numerous references, mainly to German and American literature. The two parts of the volume are separately bound in substantial dark blue cloth. The typography and paper are excellent, and there are 283 illustrations, the black and white ones in the form of graphs, outline drawings, photographs of patients or lesions, and excellent reproductions of roentgenograms. There are many good color illustrations, particularly in the sections on gastroscopy and enteroscopy. There is little to criticize except perhaps a tendency to omit some of the earlier literature. The system can be recommended as a storehouse of valuable information.

Clinical Cardiology. Edited by Franklin C. Massey, A.B., M.D., Assistant Professor of Medicine, Hahnemann Medical College, Philadelphia. Cloth. $13.50. Pp. 1100, with illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1953.

The editor has attempted to present aspects of cardiology not ordinarily covered in the textbooks of heart disease. The special problems related to the heart in the fields of pediatrics, anesthesiology, obstetrics, and psychiatry have been assigned to collaborators. The usual subject matter such as electrocardiography, roentgenography, and diagnosis and treatment of disorders commonly classified as cardiac is also included. As is often noted when there are many contributors, the chapters are not uniformly good. The editor states in the preface that controversial items are purposely included. If such were the intention, all sides of a controversial problem should have been presented. For instance, the chapter on treatment of congestive heart failure is written by Schemm, who presents mainly his own theory of edema formation and method of treatment, even though it is not accepted by cardiologists generally. Two excellent chapters deserve special mention: one on cardiac surgery by Bailey, Glover, O'Neill, and Wells, and the other on cardiac arrhythmias by Di Palma.

At the beginning of each chapter a brief biography of the author is given. Some of the authors have not been active in research in the fields assigned to them, as indicated by a lack of reference to their own work in the bibliographies that follow each chapter. Their chapters lack the freshness and spontaneity found when the author is actively engaged in research on the subject about which he writes. Illustrations and figures are adequate and in general are well chosen. Even though the book is not of uniform excellence, it should make a good reference book on cardiology for the general practitioner and the medical student. The specialist in the field of cardiology would probably prefer to consult original material or monographs.

Die Röntgenuntersuchung der Harnorgane: Lehrbuch. Von Dr. med. O. Kneise, a. o. Professor der Urologie an der Martin-Luther-Universität Halle-Wittenberg, und Dr. med. K. L. Schober, Facharzt für Urologie, chirurgische Universitäts-Klink, Halle, Saale. Fourth edition. Cloth. 32 marks. Pp. 280, with 323 illustrations. Georg Thieme, Thomas-kirchhof 21, (10b) Leipzig, C.1, 1952.

This brief monograph on roentgenologic examination of the urinary organs was intended as a textbook and as a guide to interpretation of urographic deformities caused by lesions in this tract. As the authors state, the circle of those interested would include not only urologists, but roentgenologists, internists, and various surgical specialists. The monograph contains only 323 illustrations, including drawings, abstract sketches, roentgenograms, and urograms. They portray the usual deformities seen with lesions in the urinary tract. The book is not a complete atlas of such deformities. It contains clinical discussions with most of the urograms, which take up a large part of the book, and offers additional information of questionable value to the main subject. While the text is written in an interesting and readable manner, it adds comparatively little to our present knowledge of the subject.

The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

QUERIES AND MINOR NOTES

SCHOOL VISION SURVEYS

To the Editor:—*Is it essential that mydriatics be instilled in the eyes of children when they are fitted with glasses for the correction of visual defects? In our public health program, we conduct school vision surveys, and I insist that children requiring correction of visual defects be referred to qualified ophthalmologists. While several counties in my district have no ophthalmologists, most are well supplied with optometrists. Actual examination of the eyes and prescription of glasses for children and young adults should, in my opinion, be done by well-trained ophthalmologists.*

M.D., Georgia.

Answer.—Recent textbooks on ophthalmology by medical authors recommend the use of cycloplegia for refraction of the eyes of children under age 12 years, especially if there is associated strabismus. Adequate cycloplegia and mydriasis are desirable but perhaps not necessary in all patients under age 46 who possess an effective power of accommodation. In patients 40 years and older, it is often possible to perform an adequate refraction and examination without the use of cycloplegics. For satisfactory examination of the eyes of children with high refractive errors, mydriatics are not sufficient, and frequent instillations of strong cycloplegics in high concentrations may be required. Cycloplegics can lawfully be employed in refraction only by medically trained specialists and hence are not utilized by optometrists. Medical authorities advocate the use of atropine as a cycloplegic in all children up to age 12 or 13. After this, 2% homatropine may be used in place of atropine, up to age 30. In school surveys routine use of mydriatics is not practical. Several methods of screening have been devised for selection of pupils who should be referred for special eye examinations and fitting of glasses. Visual tests can be made by teachers, nurses, trained technicians, and parents by one or more of several methods advocated by manufacturers of special equipment. A study of the methods used in 1950, 1951, and 1952, supported by the National Society for the Prevention of Blindness, the Children's Bureau of the Federal Security Agency, the division of health of the state of Missouri, the St. Louis board of education, and the Office of Naval Research, showed that none of the methods studied provides for more than rough screening. The proportion of unnecessary referrals varies little with the method of screening employed and the experience of the person doing the testing. A positive finding of a visual defect in a child is not justified on the basis of a screening test. A complete eye examination, including refraction, testing of muscle balance, field testing, and ophthalmoscopic examination with mydriasis and cycloplegia, is advocated by ophthalmologists, who, as implied in the question, are medical authorities.

SCARS ON EYELIDS OF BOXERS

To the Editor:—*A 27-year-old colored boxer complains of being easily cut about his eyelids while boxing. There is a recent scar of the left upper lid that he wishes to have excised, because it broke down in his last three bouts. I do not feel that surgery would be of any benefit, as the scar tissue is barely palpable. Is incision of scar tissue done to decrease the possibility of cutting from buried scar tissue?*

Adolph W. Vogel, M.D., Ardmore, Pa.

Answer.—This fighter probably resumed boxing before the wound was completely healed. A minimum healing period of two months should be allowed after such injuries. No chemicals, astringents, or lotions should be applied topically, because of the danger of damage to the lid or cornea, but the lid may be massaged with rose water ointment, theobroma oil (cocoa butter), or hydrous wool fat (lanolin) three times daily, not to toughen the scar but to render it more supple. Since no scar tissue was palpated, excision or plastic surgery need not be considered at this time; however, any excess scar tissue should be completely excised and the wound margins meticulously sutured, care being taken to avoid producing ectropion of the lid. Should a defect exist after excision of the scar, a full thickness skin graft may be sutured in place.

PREGNANCY AFTER YEARS OF STERILITY

To the Editor:—*A couple had had no children for years, and it was thought that the husband was sterile. After an examination done elsewhere, the husband was told that he had a high percentage of immobile spermatozoa. The wife had been taking iodine, and she persuaded her husband to take some. Within two months she became pregnant. The iodine was not taken for this specific reason but as a general tonic. Could the iodine have brought about a change in spermatogenesis?* *Robert L. Rice, M.D., Richmond, Ky.*

Answer.—The active principle of thyroid is thyroxin. Iodine is an essential part of thyroxin. The gonads often are underdeveloped and the gonadotropic factors suppressed in hypothyroidism, with resultant sterility. Fertility often can be restored in these cases by administration of thyroid. The effect on the gonad seems to take place through action on the pituitary. It is interesting to note in this connection that the aborigines were convinced that their women of marriageable age had to have access to seafood to assure fertility. High in the Andes, girls of marriageable age and pregnant mothers were fed fish eggs obtained on expeditions made regularly to the ocean for this purpose. These fresh eggs have a high vitamin and iodine content. These mountain people had learned through the centuries that seafood contains some element necessary to conception and to the maintenance of pregnancy.

PROCAINE AMIDE (PRONESTYL) HYDROCHLORIDE

To the Editor:—*A 45-year-old man who had myocardial infarction was given procaine amide (Pronestyl) hydrochloride, 0.25 gm. every four hours from the third day of the infarction, to prevent paroxysmal ventricular tachycardia. Such an arrhythmia did develop, however, on the 25th postinfarction day. There had been no prior arrhythmia. A cardiologist said this was a toxic effect of the procaine amide. Please discuss this. The patient died suddenly three days later, after quinidine therapy had converted the heart rhythm to normal.*

Rider E. Stockdale, M.D., Jasper, Texas.

Answer.—Procaine amide is a new therapeutic agent with all of the pharmacological effects of quinidine, including all the toxic effects except cinchonism. Ventricular fibrillation and tachycardia have been observed following the intravenous administration of procaine amide but, so far as is known, not following oral administration, except at much higher dosage levels. Quinidine has been given to large series of patients with myocardial infarction as a prophylactic measure against arrhythmia, with apparently good results, and an extension of this treatment with procaine amide appears logical. In the absence of an autopsy, it would not be possible to determine whether the patient's death was the result of a subsequent coronary occlusion or of a pulmonary embolism arising from a mural thrombus. The risk of either of these complications might have been reduced by the use of anticoagulant therapy.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, MAY-AUGUST 1953

Titles have been listed or abstracts made of important articles in the following journals in the Current Medical Literature Department of THE JOURNAL during the past four months. Any of the journals, except those starred, will be lent by THE JOURNAL to individual subscribers in Continental United States and Canada and to members of the American Medical Association and its student organization. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each periodical. Three journals may be borrowed at a time for a period not exceeding five days. Requests should be addressed to the Library of the American Medical Association. Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in The Journal. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation; "E," Editorial; "C," Correspondence; "ab," abstracts; the asterisk (*) indicates an original article in The Journal.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For the author index see page 1803.

A

AAT: See Parathion
ACTH: See Corticotropin
AOC: See Antibiotics
ABDOMEN: See also Ascites; Gastrointestinal Tract; Pelvis
  Adhesions: See Adhesions
  cancer, peritoneoscopy in, [Zoeckler & others] *1617
  pain after appendectomy, (reply) [Dittrich] 566
  pain, (right upper) in salpingitis, [Holm-Nielsen] 1669—ab
  rupture of wall through stria cutis distensa during cortisone or corticotropin therapy, [Lawrence & others] *1526
  surgery: See also Appendectomy; Cesarean Section; Gallbladder
  surgery, antibiotics and, [Brown] 189—ab
  surgery, immediate exploratory laparotomy during active gastrointestinal bleeding. [Bockus & others] *1228
  surgery, laparotomy, postoperative decompression by gastrotomy and Levin tube, [Gilchrist] *232
  surgery, laparotomy, Thorn's test with posterior pituitary extract, [Massone] 769—ab
  surgery, preventing atelectasis or pneumonia after, [Greene] 966—ab
  trauma to wall, acute renal insufficiency after, [Gelfand & Shapiro] *319
  Viscera: See Viscera
  wound disruption, [Schiebel] 1464—ab
ABILITY: See Efficiency; Success
ABNORMALITIES: See also Crippled; under specific organ and region as Heart
  congenital defects due to rubella; preventive use of gamma globulin in pregnancy, [Miralbell-Andreu] 1486—ab
  congenital, in rats, after excessive vitamin A, [Cohlan] 1735—ab
  genes and mermaids: causation of congenital abnormalities, 1131—ab
  in fetus from viral diseases in pregnancy, [Kaye] 85—ab
ABORTION
  etiology: exposure to lead, 1494
  habitual, frequency, Chile, 547
  incomplete, laboratory tests in, 776
  potassium in anuric tubular nephropathy after, [Dérot] 978—ab
ABRASION: See Trauma
  Therapeutic: See Sandpaper
ABRUZZI, W. A., Jr., tuberculosis among American medical students, 922—E; [Miller] 1554—C
ABSCESS: See also Ulcers; under organ affected as Brain; Lungs; Tonsils
  infected pilonidal, trypsin injection for, [Innerfield & others] *597
  subphrenic: See Diaphragm
ABSENTEEISM
  Industrial: See Industrial Health workers absenteeism
ABSORPTION: See Cartilage implants
ACADEMY: See also under names of specific academies as National Academy; New York Academy; list of Societies at end of letter S
  of Dermatology and Syphilology, symposium on industrial dermatology, 923—E
  Prizes awarded by various academies: See Prizes
ACANTHOLYSIS bullosa: See Epidermolysis bullosa
ACANTHOSIS
  nigricans (benign), benoquin for, [Lerner & Fitzpatrick] *577
ACCIDENTS: See also Trauma; Wounds
  Automobile: See Automobiles
  fatal bicycle accidents in children, U. S., 923—E
  fatal, in preschool children, (England) 1228—ab; (1901-1951, England) 1549; (U. S.) 1642
  Fourth of July, statistics on, and transportation of fireworks, [Lull] 168
  home fatalities in Britain, 1058; 1549
  Industrial: See Industrial Accidents
ACCIDENTS—Continued
  Prevention: See also National Safety Council
  prevention, courses, in, N. Y., 1541
  Traffic: See Automobiles
ACETANILID
  poisoning (chronic) with esophageal ulcer from Yum, [Wolfson & Greenberg] *910
ACET-DIA-MER-SULFONAMIDES
  N.N.R. (Hexad of Bowman) 332
ACETYLCHOLINE
  drugs affecting skeletal muscle, 495—ab
diACETYL MORPHINE: See Morphine
ACHALASIA: See Stomach cardiospasm
ACID
  acetic, biosynthesis of cholesterol, 1435—E
  acetylsalicylic, aspirin effect on rheumatic fever, [Clark] 1265—ab; (correction) 1724
  acetylsalicylic, aspirin poisoning in young child, [Gardner] 975—ab
  acetylsalicylic, repeated dosage for cancer, 1413—ab
  acetylsalicylic, treatment of periarteritis nodosa, [Dent] 1733—ab
  p-aminosalicylic, hypopotassemia with hypertension due to, [Jones] 1488—ab
  p-aminosalicylic, plus isoniazid and streptomycin in tuberculosis, [Mount] 1464—ab
  p-aminosalicylic plus streptomycin for endometrium tuberculosis, 1584
  p-aminosalicylic, plus streptomycin in pulmonary tuberculosis, [Swedish National Association] 93—ab; [Trendelburg] 365—ab
  p-aminosalicylic, plus streptomycin, roentgen evaluation, [Pitts & others] *887
  p-aminosalicylic, severe hypersensitivity simulating mononucleosis or hepatitis, [Lichtenstein & Cannemeyer] *606
  p-aminosalicylic, special solution, hemolytic anemia after ingesting, [Lust] 1281—ab
  p-aminosalicylic, treatment, glycosuria and hyperglycemia after, [Robel] 1488—ab
  p-aminosalicylic treatment, hypokalemia during, [McIntyre] 967—ab
  p-aminosalicylic treatment of brucella infections, [Terni] 193—ab
  p-aminosalicylic, treatment of urogenital tuberculosis, [Cibert] 1077—ab
  p-aminosalicylic, vs. isoniazid, in tuberculosis, London, 548
  Ascorbic: See also Calcium ascorbate; Sodium ascorbate
  ascorbic, administration of iron; which form is best tolerated by intestines? 1393
  ascorbic, adrenocortical response to, in children vs. adults, [Sprechler] 1275—ab
  ascorbic, biosynthesis of cholesterol, 1435—E
  ascorbic, deficiency effect on healed wounds (scar tissue), 334—E
  ascorbic, mechanism of Filatov's tissue therapy, [Li Voti] 1736—ab
  ascorbic, meralluride with, evaluate diuretics given orally, [Greiner & Gold] *1130
  ascorbic—U.S.P. N.N.R., (Sherman) 332
  Carbolic: See Phenol
  Cevitamic: See Acid, ascorbic
  folic, antagonists plus steroid hormones for acute leukemia, [Magnin] 364—ab
  glutamic, treatment of epilepsy, [Putnam & Rothenberg] *1400
  guanidineacetic, and betaine treatment of poliomyelitis, [Watkins] 1471—ab
  hydrochloric, administration of iron: which form is best tolerated by intestines? 1393
  hydrofluoric, burns, treatment with "triple dyes" and calcium gluconate locally, 1493
  iodoalphionic (Priodax), pseudoalbuminuria after ingestion, [Seedorf & others] *1332
  iodopanoic (Telepaque), pseudoalbuminuria after, [Seedorf & others] *1332
  Isonicotinic Hydrazide: See Iproniazid; Isoniazid
  lysergic thylamide, for mental disorders, [Solms] 1487—ab
  nicotinic, biosynthesis in animal tissues, Italy, 1453
  Nicotinic, diethylamide of: See Nikethamide
  panthothenic, biosynthesis of cholesterol, 1435—E
ACID BASE BALANCE: See Acidosis
ACIDOSIS: See also Ketosis
  hyperchloremic, after ureterosigmoidostomy, 334—E
ACNE
  problem, [Becker] 478—ab
ACOSTA, J. del C., appointed president of Confederación Médica Panamericana, 753
ACROCEPHALY (oxycephaly)
  surgical treatment: creating movable "cranial ribs," [Desbuquois] 1574—ab
ACRODERMATITIS
  enteropathica, diodoquin for, [Dillaha & others] *509; (correction) 1643
ACROMEGALY
  secondary joint involvement, Primer on Rheumatic Diseases, *530
ACROPARESTHESIA
  in 51 year old woman, 374
ACROPATHY
  ulceromutilating, familial ulcerative disease of extremities, Belgium, 350
ACTA: See Journals
ACTH: See Corticotropin
ACTINOMYCES, Antibiotic Prepared from: See Streptomycin
ACTINOMYCOSIS
  accidental transmission from man to man, 1394
  in Mexico, 1360
  of spine, 401—ab
ACTIVITY
  Following operation or illness; See Convalescence
ADAMANTINOMA
  of mandible, 881
ADAPTATION
  syndrome, [Selye] *1207
ADDICTION: See Alcoholism; Cannabis Sativa; Narcotics
ADDISON'S ANEMIA: See Anemia, Pernicious
ADDISON'S DISEASE
  diagnosis, desoxycortisone acetate in, [Michon] 97—ab
  treatment, licorice and cortisone in, [Borst] 1383—ab
  treatment, licorice, (biochemists discuss) 74; [Card] 1383—ab
ADDRESSES: See Lectures
ADENITIS: See Lymphatic System
ADENOCARCINOMA
  of uterine corpus, 499—ab; 996—ab
ADENOMA
  multiple, involving parathyroids, pituitary and pancreatic islets, [Underdahl] 89—ab
  Nontoxic, of Thyroid: See Goiter
  of head of pancreas, surgery for hypoglycemia due to, [Voszschulte] 283—ab
  solitary, benign of thyroid, 1583
  solitary of bronchi, resection for, [Hood & others] *1185
  Toxic, of Thyroid: See Goiter, Toxic
ADENOMYOSIS: See Endometriosis
ADHESIONS
  intestinal obstruction from, [Parker] 1267—ab
  intestinal, preventing with streptokinase, streptodornase, and pancreatic enzymes, [Cavallini-Francolini] 1078—ab
  traumatic autoplastic implants of splenic tissue, [Berry & Erdman] *1227
ADIPHENINE
  treatment of peptic ulcer, 1289
ADIPOSITY: See Obesity
ADOLESCENCE
  Personal Health for Girls (film review), 648
  Personal Hygiene for Boys (film review), 648
  pseudoprecocious puberty from taking estrogens in girl of 4, [Cook] 1471—ab
ADRENALECTOMY: See Adrenals, surgery
ADRENALIN: See Epinephrine
ADRENALS: See also Addison's Disease
  Adrenocorticotropic Hormone: See Corticotropin
  adrenogenital syndrome before and after taking cortisone, [Franckson] 1573—ab
  celiac accessory, [Graham] 88—ab
  Cortex Compound E: See Cortisone
  cortex failure (acute) cause of shock and death, [Taylor] 1266—ab

ADRENALS—Continued
  cortex, function in anorexia nervosa, [Altschule] 1735—ab
  cortex, function in premature infants, [Lanman] 363—ab
  cortex, function measured with ACTH, 1129—ab
  cortex, hormonal cause of cardiac hypertrophy, [von Metzler] 93—ab
  cortex insufficiency, emergency treatment, 1494
  cortex, postoperative insufficiency, in patients previously treated with cortisone, [Salassa & others] *1509
  cortex, response to corticotropin, cortisone, and ascorbic acid in children vs. adults, [Sprechler] 1275—ab
  Cortex Hormone (Crystalline): See Desoxycorticosterone
  hemorrhage, apoplexy during corticotropin therapy of ulcerative colitis, [Wilson & Roth] *230
  hemorrhage, spontaneous idiopathic bilateral apoplexy with hypertension, [Greene] *133; (additional case report) [Salomon] 871—C; (comment on Dr. Greene's article) [Bauer] 961—C
  Hormone (Sympathetic): See Epinephrine
  insufficiency, desoxycortisone acetate in diagnosis, [Michon] 97—ab
  steroids and corticotropin in alcoholism, [Voegtlin] 1074—ab
  surgery, adrenalectomy for thromboangiitis, [Tingaud] 875—ab
  surgery, late complementary adrenalectomy in thromboangiitis after sympathectomy, [Leriche] 1077—ab
  surgery, remission of Cushing's syndrome after bilateral hemiadrenalectomy, [Kupperman] 361—ab
  surgery, subtotal adrenalectomy for Cushing's syndrome, [Walters] 357—ab
  tumors, pheochromocytoma; clinicopathological study, surgery successful, Brazil, 1451
  tumors, pheochromocytoma, hemiplegia from, [ReMine & others] *808
ADRENERGIC BLOCKING AGENTS
  Phentolamine Hydrochloride, N.N.R., (description) 1533; (Ciba) 1534
  Phentolamine Methanesulfonate, N.N.R., (description) 1534; (Ciba) 1535
ADRENOCORTICOTROPIC HORMONE: See Corticotropin
ADVERTISING
  Alameda County Medical Society, on medical care, [Allen] *658
  chlorophyll as deodorant, [Thimann] 869—C
  of medical products, A.M.A. resolution on, 844; (Reference Committee report) 1053
  television and radio, portrayal of physicians in, 822—E; (A.M.A. resolutions on) 847, 848
ADVISORY
  Committee on Internships, Council report, 829
AEROMEDICINE: See Aviation medicine
AERONAUTICS: See Aviation
AEROSOLS
  Administration by: See Antibiotics; Isoniazid
AEROSPORIN: See Polymyxin B Sulfate
AEROTITIS: See Otitis Media
AFIBRINOGENEMIA: See Blood
AFTERBIRTH: See Placenta
AGE
  Adolescent: See Adolescence
  distribution of nursing home patients, [Goodman] *1337
  grand mal seizures in patients over 35, [Berlin] *794
  Old Age: See Old Age
AGENE: See Nitrogen trichloride
AGGLUTINATION
  of erythrocytes, effect of antihistamines on, [Lucia] 1468—ab
AGGLUTININS
  cold, acute thrombopenic purpura with autoagglutination; antiplatelet agglutinin, [Dausset] 1487—ab
  Rh: See Rh Factor
  typhoid, in trichinosis, [Kushlan] *221
AGGLUTINOGEN
  Rh: See Rh Factor
AGRANULOCYTOSIS
  etiology: methimazole, [Rosenbaum & Reveno] *27
  etiology: phenylbutazone (butazolidin), fatal case, [Steinberg & others] *33
  etiology: phenylbutazone; precautions suggested, [Strazza] 183—C
  etiology: sulfisoxazole, [McCluskey] *232
  granulocytopenia caused by drug idiosyncrasy, (Council report) [Osgood] *816; 823—E
  treatment, corticotropin, [McCluskey] *232; [Schulten] 1480—ab
AGRICULTURE: See Farm; Farmers
AIR: See also Humidity; Oxygen
  conditioning, treatment of miliaria, [Shelley] *670
  drying (mechanical) of hands after preoperative scrubbing, [Walker] 974—ab
  Dust in, as Industrial Hazard: See Pneumoconiosis
AIR—Continued
  Embolism: See Embolism
  exposure to, in treatment of burns in children, [Taylor] 366—ab; 910—ab; [Artz] 1370—ab
  Injection: See Pneumoperitoneum; Pneumothorax, Artificial
  mask for giving, [Stodsky] *1714
  Pollution Control Association, 340
  Presence of Air in Cavity: See Pneumothorax
  research, grant for, N. Y., 1154
AIR FORCE: See Aviation, U. S. Air Force
AIR PASSAGES: See Respiratory System
AIRPLANES: See Aviation
ALAMEDA County Medical Society, [Allen] *658
ALARM
  electric automatic, conditioned response to, to control nocturnal enuresis, [Geppert] *381; [Fischer] 1732—C
ALASKA
  health problems, grant for study, Pa., 1248
ALBUMIN
  in Blood: See Blood proteins
  in Urine: See Albuminuria
  necessity for adding to serum in crossmatching, [Grove-Rasmussen] 92—ab
  Radioactive Iodinated: See Blood proteins
ALBUMINURIA
  telepaque and pseudoalbuminuria, [Seedorf & others] *1332
ALCOHOL
  Addicts: See Alcoholism
  Antabuse Reaction: See Alcoholism
  injection (intravenous) effect on cerebral blood flow and metabolism, [Battey & others] *6
  Propyl: See Isopropyl Alcohol
  studies, conference on, Wis., 746
  tobacco amblyopia, [Maxwell] 1176—ab
  treatment, danger of combining morphine with, Denmark, [Møller] 288—ab; 352
  use by ulcer patients, 774
  Yale Center of Alcohol Studies, industrial institute, Conn., 1152
ALCOHOLISM: See also "Drunkenness" under Medicolegal Abstracts at end of letter M
  clinic for alcoholics, N. Y., 858
  death from morphine in persons under influence of alcohol, [Møller] 288—ab; 352
  delirium tremens, methods of treatment, [Smith] *384
  diagnosis, blood alcohol determinations, 6 to 8 hours after blood is drawn, 483
  effect on cerebral blood flow and metabolism, [Battey & others] *6
  Mallory-Weiss syndrome, 1292
  Portal House moves, Ill., 1054
  problem drinkers, 140—ab
  treatment, adrenal steroids and corticotropin, [Voegtlin] 1074—ab
  treatment, antabuse-alcohol reaction, toxic signs; electrocardiographic changes, [Markham & Hoff] *1597
  treatment, care of alcoholics, Finland, 958
ALDRIN (Octalene)
  Committee report on names for insecticides, *819
ALIENS: See Physicians, foreign
ALIMENTARY TRACT: See Digestive System; Gastrointestinal System
ALKALOSIS: See Acidosis
ALKAPTONURIA: See Ochronosis; Urine
ALKAVERVIR (Veriloid)
  treatment plus hexamethonium bromide in hypertension, Israel, 260
ALLEN (Raymond B.) Award: See Prizes
ALLEN Starvation Treatment: See Diabetes Mellitus, treatment
ALLERGY: See also Asthma; Dermatitis venenata; Eczema; Hay Fever; Urticaria
  A.M.A. Session on, (minutes) 933
  antagonistic to diabetes, [Gutmann] 1572—ab
  atopic dermatitis caused by inhalant antigens, [Diamond] 1465—ab
  automobile accidents due to, 296
  booster tetanus injection advisable in allergic child? 1084
  conditions in industry, prevention and control, [Suskind] 967—ab
  course on allergic disease at Hopital Broussais, Paris, 1443
  diagnosis, multiple positive reactions to allergic skin tests, 1498
  fellowship in, at Northwestern, 536
  mucoproteins of nasal mucosa of patients, [Rappaport] 88—ab
  preleukemic acute human leukemia, [Block & others] *1018
  regional enteritis, [Rowe] 1664—ab
  sensitivity to _p_-aminosalicylic acid simulating mononucleosis or hepatitis, [Lichtenstein & Cannemeyer] *606
  sensitivity to cigarette smoke, [Friedell] *897
  sensitivity to cinnamon oil in tooth paste cause of cheilitis, [Laubach & others] *404
  sensitivity to contrast materials during excretory urography, 655
  sensitivity to corticotropin: aplastic anemia, [Snively & others] *1223
ALLERGY—Continued
  sensitivity to cottonseed, 775
  sensitivity to drugs; crossed allergies, Italy, 181
  sensitivity to drugs, hypoplastic anemias and related syndromes caused by, (Council report) [Osgood] *816; 823—E
  sensitivity to dust and feathers in sinusitis, 1676
  sensitivity to fiberglas, 1290
  Sensitivtiy to Food: See Food
  sensitivity to "improved" flour, London, 353; [Pollock] 1066—C; [Sheldon] 1179—ab
  sensitivity to influenza virus prepared from egg material, 775
  sensitivity to insulin, (reply) [Dolger] 296

  "You and the World" on CBS, 243
RADIOACTIVE
  Carbon: See Carbon
  Cobalt: See Cobalt
  contamination of hands, soap powder-wood flour mixture, to remove, [Gregory] 365—ab
  Cortisone: See Cortisone
  Gold: See Gold
  Iodinated Albumin: See Blood proteins
  Iodine: See Iodine, radioactive
  Isotopes: See also Radiation, ionizing
  isotopes, course on, at U. of California, 1437
  isotopes, *distribution* in body, International *Congress discuss*, *628*
  isotopes, jet injection, 532—E
  isotopes, therapeutic, 1215—ab
  Phosphorus: See *Phosphorus*
  Scintillation Counter: See Scintillation
RADIOBIOLOGY
  one year instruction in available, 257
RADIOIODINE: See Iodine, radioactive
RADIOLOGY: See also Radiation
  course in, Minn., 59
  health training program, 1062
  International Congress of at Copenhagen, *July 19-24, 748*
  Midsummer Conference, Denver, 1250
  Picker Foundation grants for research, 342
  Radiological Society *of New York State*, organized, 1247
  work, figuring in units, London, 1064
RADIOTHERAPY: See Radiation *therapy*
RADIUM
  gamma irradiation effect on human skin, [Wachsmann] 1488—ab
  hospital, annual report for 1951, Norway, 549
  medical supervision of persons in radiological service, *Norway*, 1550
RADIUS
  fracture (Colle's), causalgia after, 292
RAGWEED
  relief from pollens, 1144—E
RAILROADS
  dining car sanitation, 956
  excreta from toilets on trains; role in transmission of poliomyelitis, 1183
  Pennsylvania, expands medical service, 1642
RASH: See *Eruptions*
RAT-DETH: See *Warfarin*
RATIONING: See Food
RATS
  diagnosis of trichinosis using, [Beck] 274—ab
  typhus in *rats* and rat ectoparasites, [illegible]
  [illegible] es
  [illegible] *disease*, 564
  Raynaud's phenomenon and, [Scherbel] 1463—ab
RAYS: See Radiation
RAZORS
  sterilization to prevent homologous serum hepatitis, (reply), [Murray] 656
READER (Ruth Berger) Fellowship: See *Fellowships*
RECIPROCITY: See Licensure
von RECKLINGHAUSEN DISEASE: See Neuro*fibromatosis*
RECORD Librarians: See Medical Record Librarians
RECORDING: See Oscillometer, recording; Tape recording
RECORDS: See Medical Records
RECREATION: See also Leisure Corner; Physicians, avocations
  County and Community Recreation (film review), 965
RECTOCELE
  repair of; pregnancy advisable? 1582
RECTUM: See also Anus
  Administration by: See Enema
  cancer (inoperable), dienestrol *for*, [Erisbacher] 195—ab
  lacerations from foreign bodies (enema tips, thermometers, suppositories), simplified treatment, [Turell] *136
  procidentia, Thiersch operation for, [Berkowitz] 1563—ab
  surgery, anastomosis of transverse colon to, Brazil, 470
  Varix: See Hemorrhoids
RECUMBENCY: See Convalescence; Posture
RECURRENT FEVER: See Relapsing Fever
RED CELLS: See Erythrocytes
RED CROSS, AMERICAN
  National Blood Program, (need for blood) 538; (A.M.A. Committee report) 831; 833
REDUCING Treatment: See Obesity
REFLEX
  conditioned response to automatic electric alarm in treatment of nocturnal enuresis, [Geppert] *381; [Fischer] 1732—C
REFRESHER Courses: See Education, Medical, graduate
REFRIGERATION
  Therapeutic Use: See Cold, therapeutic use
REFUSE
  garbage fed hogs and trichinosis, 241—E
REGISTRATION: See Harrison Narcotic Act; Licensure
REGITINE: See Phentolamine
REHABILITATION
  A.M.A. Council on Physical Medicine and: See *American* Medical Association
  clinical fellowships in, 349
  doctor's part in, 235
  mission to Korea, 174; [Rusk] 724
REHYDRATION: See Hydration
REITER'S SYNDROME
  [Hall] 1169—ab
  Primer on Rheumatic Diseases, *529
  treatment, corticotropin, [Larson] 1070—ab
RELAPSING FEVER
  research on, Mexico, 1360
RELAXANTS; Relaxation: See Muscles
RELIGION: See also Buddhism
  A.M.A. [illegible] Freedom Under God, 843
[illegible]
REMUNERATION: See Fees; Income; Wages
RENAL: [illegible]
RENDU-OSLER-WEBER [illegible]: See Telangiectasia
RENNIN
  pathogenesis of essential hypertension, 1435—E
  treatment of experimental renal hypertension, [Wakerlin] 1666—ab
REPRINTS: See Journals
REPRODUCTION: See Coitus; *Contraception*; [illegible]; [illegible]; Sterility
RESEARCH: See also under specific headings as Cancer; Eyes
  Clinical Research Board, in relation to National Health Service, London, *1730*
  Council for Economic Security, survey of prolonged nonoccupational illness by, (Council article) *1457
  Fellowships: See Fellowships
  financial compensation for the investigator, [*Allen*] **660*
  Foundation: See Foundations
  Grants for: See Fellowships; Foundations
  Health Research, Inc., formed by New York State, 1721
  medical, by pharmaceutical firms, [Serringhaus]*1525
  medical, *federal* bills on, A.M.A. attitude on, 1047

  medical, Kodak Pty (Ltd.) finances, Australia, 624
  Medical Research Council: See Medical Research Council
  National Research Council: See National Research Council
  program, Coral Atoll, sponsored by National Academy of Sciences, *1162*
  Prizes for: See Prizes
  volunteers to aid, convalescent gamma globulin fails to protect against homologous serum hepatitis, [Drake & others] *690
  volunteers to aid, Walter Reed Society honors Dr. T. Koritz, Ill., 944
RESERVE Officers: See Navy, U. S.
RESIDENCE: See Home
RESIDENTS AND RESIDENCIES: See also Fellowships; Interns and Internships
  American Academy of Pediatrics fellowship residency, 464
  A.M.A. resolution on reevaluation, 848
  approved by A.M.A., additional list, 185
  foreign physicians as residents *in* U. S., statement by Office of Defense Mobilization, [Aufranc] 869—C

RESIDENTS AND RESIDENCIES—Continued
  Frank B. Cross prize, 249
  licensure requirements in hospitals, *436; *438
  new residency program, N. Y., 537
  practical instruction for interns, D.C., 1638
  psychiatric and neurological residencies, 258
  residencies available at VA hospitals, (Kan.) 179; (Tex.) 1062
RESINS
  cation exchange, effect on hypertension, congestive heart failure and edema, [deSoldati] 1279—ab
RESORTS: See Tourists
RESPIRATION
  Artificial. See also Respirator; Resuscitation
  artificial, assay of 4 resuscitation procedures, [Swann] 479—ab
  artificial, experiments of Dr. Koritz on himself; Walter Reed Society honors him, 944
  artificial, medical students replace iron lung in poliomyelitis outbreak, Denmark, 624
  artificial, treatment of impaired respiration in bulbar poliomyelitis, [Frank] 757—C
  Disorders: See also Asphyxia; Dyspnea
  disorders, in *postmeasles encephalitis*, [Weinstein] 1560—ab
  disorders, tracheal obstruction from benign lymphoid hyperplasia, [Olson] 1561—ab
  expiration function of abdominal muscles, *[Campbell] 1670*—ab
  hyperventilation in diabetes mellitus, [Musser & others] *1113
  ventilation, in congenital absence of main branch of pulmonary artery, [Steinberg & *others*] *1216
RESPIRATORS: See also Respiration, artificial
  mechanical, importance of negative pressure phase in, [Maloney & others] *212
  New York city plan for care of poliomyelitis patients in, [Wallace & Baumgartner] *1506
  Poliomyelitis Respirator Center, courses at, Texas, 1248
  Vital Capacity: See Vital Capacity
RESPIRATORY METABOLISM: See Metabolism, basal
RESPIRATORY SYSTEM: See also Bronchus; Lungs; *Pleura*; *Trachea*
  conditions with thick sputum, trypsin (Tryptar) inhalations in, [Unger & Unger] *1109
  Disorders: See also Bronchiectasis; Pneumonoconiosis
  disorders, atopic dermatitis caused by inhalant *antigens, [Diamond] 1465—ab*
  disorders in welders, [Charr] *1520
  Infection: See Bronchopneumonia; Influenza; Pneumonia; Tuberculosis of Lungs
  insufficiency (acute) in poliomyelitis, [Lassen] *286*—ab
RESPONSIBILITY: See Malpractice
REST: See *also* Sleep
  Bed Rest: See also Convalescence
  bed rest in minimal pulmonary tuberculosis, *[Mitchell] 1463—ab*
  bed rest in tuberculous pleurisy with effusion, [Mitchell] 1464—ab
  why do kidneys function better when patient *is at rest? 1291*
RESTLESS LEG SYNDROME
  relief with quinidine sulfate, (reply) [Lowell] 200
RESUSCITATION: See also Respiration, artifi*cial; Respirators*
  cardiac, course at Western Reserve, 252
  cardiac, especially by massage, drugs, defibrillation, [Leeds] *1409
  cytochrome C in, [Battezzatti] 369—ab
  of asphyxiated newborn infant; use of Jackson infant laryngoscope and bronchoscope, also Kreiselman infant resuscitator, [Beattie & Zwerling] *216; [Greenhill] 961—C
  of newborn, method and machine for, [Mann] *1333; (correction) 1643
  procedures, 4 methods, [Swann] 479—ab
  [illegible] tie & Zwerling] *216
[illegible] SYSTEM
  index (Sandor's) to measure serum lipoproteins, Paris, 1551
RETICULOENDOTHELIOSIS
  in lupus erythematosus disseminatus, Brazil, 1358
RETINA
  crush syndrome affecting, [Weinstein] 1658—ab
  detachment, scleral resection for, [Pischel] 1658—ab
  Foundation Service fellowship, 1641
  Inflammation: See Retinitis
RETINITIS
  pigmentosa, ocular implants for, Paris, 868
  pigmentosa, placental grafts for, Turkey, 1455
RETROLENTAL Fibroplasia: See Lens, Crystalline
[illegible]: See Pneumo-
[illegible] See Prostatectomy
REULING, J. R., speaker of A.M.A. House of Delegates, 720
REVISTA: See Journals
REWARDS: See Prizes
Rh FACTOR: See also Erythroblastosis, Fetal
  blood grouping tests for exclusion of paternity, [Unger] *1006
  in fourth pregnancy, *199*
  induction of labor in Rh-negative mother, 295

RH FACTOR—Continued
  mother nurs[illegible] 1396
  necessity of [illegible] n cross-matching, [illegible] b
  Rh-negative [illegible] man a transfusio[illegible] 07
  stillbirths (6) relation to, 1582
  transfusion reaction after using group O Rh-negative blood, [Tovey] 1380—ab
  tubal ligation in Rh-negative mother, 295; *(reply) [Cone] 1500*
[illegible] See Heart disease [illegible] nflammation; Myocarditis
  course in, U. of Utah, 341
  Institute in October, Ill., 1054
  Primer on Rheumatic Diseases, *329
  recurrences, preventing, 1083
  treatment, cortisone or corticotropin indicated in all cases? 1493
  treatment, HPC and aspirin, [Clark] 1265—ab; (correction) 1724
  treatment, home care of children, Montefiore *Hospital plan, [Young & Rodstein]* *987
RHEUMATISM: See also Arthritis
  Acute Articular: See Rheumatic Fever
  American Rheumatism Ass'n., award to Dr. Swift, *1247*
  Chilean Congress on Rheumatic Diseases, 957
  classification of, *325
  International Congress of Rheumatic Diseases Aug. 24-28, at Geneva, Switzerland, 540
  nonarticular, *526
  palindromic, *530
  Primer on Rheumatic Diseases, 4th ed., *323; *405; *522
  psychogenic, Chile, 957
  psychogenic, *529
  sleep, acroparesthesia, 374
  Società Italiana di Reumatologia prize, 1056
RHEUMATOID ARTHRITIS: See Arthritis, Rheumatoid
RHINITIS
  purulent, erythromycin for, [Herrell & others] *1605
  Vasomotor: See Hay Fever
RHINOPHARYNX: See Nasopharynx
RHINORRHEA
  Cerebrospinal: See Cerebrospinal Fluid
RHUS
  antigen injections, exacerbation of ivy dermatitis by, [Reyer] 1168—ab
  treatment, 2,4-D most effective on poison ivy, 1144—E
RHYTHM
  Society for the Study of Biological Rhythms, *1724*
RIBOFLAVIN
  cocarboxylase effect on urinary excretion of in heart disease, Italy, 1452
RIBS
  painful swelling of costal cartilages, Tietze's syndrome, [Motulsky & Rohn] *504
  stress fractures in successive pregnancies, [Marsh] *26
RICHARDSON Test: See Pregnancy, diagnosis
RICHMOND, VIRGINIA
  medical care for indigent, Council report, 268
RICKETTS Prize: See Prizes
RICKETTSIA: See Q Fever; Rocky Mountain *Spotted* Fever; Typhus
RIGIDITY
  muscular, 20% carbon dioxide inhalation in, [Fay] *1623
RIMIFON: See Isoniazid
RINGER'S SOLUTION
  lactated, fluid and electrolyte balance in burns, [Reiss & others] *1309
RINGWORM: See Dermatophytosis
  of Scalp: See Tinea capitis
RISING, Early Rising after Operation, etc.: See Convalescence
ROAD Accidents: See Automobiles; Bicycles
ROCKEFELLER
  Foundation: See Foundations
  Institute for Medical Research, (Dr. Gasser retires as director) 1154; (elects new officers) 1439
ROCKY MOUNTAIN SPOTTED FEVER
  warning against wood ticks, Ill., 1246
RODENTICIDES
  use and abuse of generic (coined common) names for (Committee report) *818
RODENTS: See Rats
RO-DETH: See Warfarin
ROENTGEN RAYS
  burns from diffraction apparatus simulating infections, [Watrous & others] *513
  cataract, 334—E
  damage, blood picture as indicator of, [Langendorff] *1488—ab*
  departments in hospitals, *156
  diagnosis (erroneous) [illegible] foration by foreign [illegible]
  diagnosis, hazards of [illegible] tion of colon and [illegible]
  diagnosis, high voltage X-rays to discover colonic polyps, [Gianturco] 1566—ab
  diagnosis in regional ileitis, 199
  [illegible] breast cancer, [illegible] 6
  [illegible] Rays, diagnosis; Urography; under specific organs and regions as Brain; Gallbladder; Spinal Canal; Thorax, chest x-rays

ROENTGEN RAYS—Continued
  examination, new techniques, Paris, 1551
  examination, sensitivity to contrast materials, 655
  examination studies during pregnancy; effect on fetus, (reply) [Schwarz] 776
  Irradiation: See Roentgen Therapy
  medical supervision of persons working with, Norway, 1550
  photofluorography to detect unsuspected gastric *neoplasms, [Wigh] 273*—ab
  sensitivity of renal cancer, [Heinrich] 99—ab
  technicians in hospitals, statistics on, *159; *160; 165—E
  technicians, schools for, approved by A.M.A., *161
ROENTGEN THERAPY
  effect on human skin, [Wachsmann] 1488—ab
  irradiation intoxication, [Zuppinger] 100—ab
  of arachnoiditis, 774
  of benign uterine hemorrhages, 564
  of hemangioma, [Montag] 480—ab
  of psoriasis with Bucky rays or grenz rays, 1395
ROENTGENOGRAPHY: See Roentgen Rays diagnosis; Roentgen Rays, examination
ROOMS: See Flooring; Homes
ROSACEA
  role of emotions in, [Frumess] *1419
ROSEOLA
  infantum or "3 day measles," 1395
ROSS (Will) Medal: See Prizes
ROUNDWORMS: See Ascaris; Strongyloidiasis
ROYAL COLLEGE
  of Physicians, London, (report on teaching of social medicine) 261; (report on student health services) 262
  of Surgeons, London, *(addition to) 1258;* (Queen Elizabeth visits) 1453
RUBBER
  bands, etc., dermatoses in office workers, [Morris] *1218
  foam rubber sponge used for intestinal anastomosis, [Berman] 1371—ab
RUBBING ALCOHOL: See Isopropyl Alcohol
RUBELLA
  congenital defects due to; prophylactic use of gamma globulin in pregnancy, [Miralbell-Andreu] 1486—ab
  in pregnancy: effect on fetus, [Kaye] 85—ab
  prevention, convalescent gamma globulin for, [Anderson] 769—ab
RUBEOLA: See Measles
"RULE OF NINES"
  to determine percentage of body surface affected in burns, [Reiss & others] *1309
RUNYON (Damon) Fund: See Foundations
RUPTURE: See Hernia; under *specific organs* and regions as Abdomen; Aortic Valve; Bladder; Spine, intervertebral disk; Uterus
RURAL COMMUNITIES: See also *Farm;* Farmers
  A.M.A. Council on Rural Health: *See American* Medical Association
  County Health Department: See Health
  health bulletin: "Parade of Progress," 459
  National Conference on Rural Health, digest of proceedings available from A.M.A., 1538
RUSH (Benjamin) Award: See Prizes
RUSK, H., address at New York *meeting,* 724
RUST
  should tetanus antitoxin be given 5 days after stepping on rusty nail? 200
RUTGERS 612: See Ethohexadiol

S

SACHS, ERNEST, errors in his HISTORY OF NEUROLOGICAL SURGERY, [Wartenberg] 184—C

  surgery, resection: close partially gastric stump before making anastomosis with jejunum, 484
  tumors (unsuspected), photofluorography to detect, [Wigh] 273—ab
  Ulcer: See Peptic Ulcer
STOMACHACHE
  brass pot (chimboo) to cure, in India, (pictures) [Oliver] 1456—C
STOMATITIS
  caused by cinnamon oil in tooth paste, [Laubach & others] *404
  herpetic, and herpangina, [Schlack] 367—ab
STONES: See Calculi (cross reference)
STOOLS: See Feces
STORAGE of Blood: See Blood Transfusion, blood bank
STRAIN: See Effort; Stress
STRAUSS COMMISSION
  report on extending "Doctor-Draft Law," 165—E; 166
STREET
  Accidents: See Automobiles, accidents
STREPTOCOCCUS
  beta hemolytic, infection; treated at home; methods evaluated, [Breese] *10
  Infection: See Endocarditis; Rheumatic Fever; Scarlet Fever; Throat, sore
  pharyngitis, what concentration of penicillin in blood sufficient to cure, 1583
STREPTOKINASE-STREPTODORNASE (Varidase)
  prevent intestinal adhesions, [Cavallini-Francolini] 1078—ab
  treatment of hemothorax after extrapleural pneumothorax, [Miadonna] 97—ab
  treatment, solution given intrapleurally, allergic reaction, [Goehring & Grant] *1429

STREPTOMYCIN
  calcium chloride complex, local pain from intramuscular use, [Long & others] *25
  Dihydro—:See Dihydrostreptomycin
  effect on acoustic nerve, [Velasco] 1574—ab; [Heck] 1662—ab
  effect on bacterial resistance to isoniazid, [U. S. Public Health Service] 1661—ab
  Treatment: See also Eyes, tuberculosis; Knee, tuberculosis; Meningitis, tuberculous; Salmonella; Tuberculosis of Lung
  treatment, alone and combined with isonazid and PAS in pulmonary tuberculosis, [Mount] 1464—ab
  treatment, intramuscular plus oral isoniazid in tuberculous meningoencephalitis, [Suárez] 287—ab
  treatment of bacterial meningitis, [Alexander] *662
  treatment plus *p*-aminosalicylic acid in pulmonary tuberculosis, [Swedish National Association Against Tuberculosis] 93—ab; [Trendelenburg] 365—ab
  treatment plus *p*-aminosalicylic acid in tuberculosis of endometrium, 1584
  treatment plus congo red in tuberculous meningitis, [Pescetti] 1179—ab
  treatment plus isoniazid in pulmonary tuberculosis, [Pitts & others] *886
  treatment plus penicillin in diphtheria, [Schneider] 976—ab
  treatment vs. isoniazid and PAS in tuberculosis, London, 548
STREPTOTRICHOSIS: See Actinomycosis
STRESS
  emergency treatment of adrenocortical insufficiency, 1494
  extrinsic source of, in "functional" disorders, [Watts & Wilbur] *1192
  fractures of ribs in successive pregnancies, [Marsh] *26
  how hydrocortisone affects resistance of tissues to injury, [Selye] *1207
  Incontinence: See Urine
STRIA CUTIS DISTENSA
  rupture of abdominal wall through, during cortisone or corticotropin therapy, [Lawrence & others] *1526
"STROKES": See Brain hemorrhage
STRONGYLOIDIASIS
  treatment, 984
STRUMA: See Goiter
  Lymphomatosa (Hashimoto's Disease): See Thyroid
STUBBS Oration: See Lectures

  Scholarships: See Scholarships
  Teaching: See Education, Medical
  tuberculosis in, 922—E; [Miller] 1554—C
STUTTERING: See Speech defects
SUBDURAL: See Meninges
SUBMARINES
  medicine, conference by U. S. Navy, 623
SUBPHRENIC: See Diaphragm
SUCCESS
  basis of: persistently purposeful, hard work, 237—ab
  of applicants for research fellowships of Rockefeller Foundation, [Bowen] *693
SUCCINYLCHOLINE
  chloride (anectine) name accepted by Council, 709
  in electric shock, [Adderley] 95—ab
  iodide, use in electroshock therapy, [Holmberg] 1384—ab
SUCTION: See also Pressure, negative
  in resuscitation of asphyxiated newborn, [Beattie & Zwerling] *216
  negative pressure to determine capillary fragility with petechiometer, [Perry] 1373—ab
  pneumatic, applied to legs to induce hypotension in neurosurgery, [James] 768—ab
SUDAN III
  stain for lipid bodies in urinary sediment, [Parrish & Alpert] *1713
SUDECK'S SYNDROME
  dystrophy of extremities, [Hackethal] 1476—ab
SUGAR: See Glucose
  in Blood: See Blood
  in Urine: See Diabetes Mellitus; Glycosuria; Urine
SUICIDE
  attempted, by drinking ammonia, causes jejunal stricture and severe potassium deficiency, [Chassin & Slattery] *134
  attempted, future of patients recovering from, Denmark, 1649
  rate at record low, 1313—ab
SULESTREX: See Piperazine Estrone Sulfate
SULFALUMIN: See Aluminum *p*-aminobenzene
SULFHYDRYL: See Calsulfhydyl
SULFISOXAZOLE (Gantrisin)
  Diethanolamine, N.N.R., (Hoffmann-LaRoche), 921
  N.N.R., (Hoffmann-LaRoche), 1339
  toxicity: agranulocytosis; corticotropin for, [McCluskey] *232
SULFOBROMOPHTHALEIN SODIUM (Bromosulphalein)
  liver function test, near fatal reaction, [Mc Vay] *1622
  liver function test, results affected by multiple transfusions? 198
SULFONAMIDES
  Combinations: See Acet-Dia-Mer-Sulfonamides
  Intestinal flora changed by, 1676
  treatment of bacterial meningitis, [Alexander] *662
  treatment of streptococcic infections in the home, [Breese] *10
  treatment plus penicillin in gonorrhea, [Horne] 94—ab
SULFONES
  diazotized argentic (Di-Atox argentique-Jeanson) in leprosy, [Tzanck] 978—ab
SUMMER
  Camps: See Camps
SUPERFETATION
  can twins have different fathers? 199
SUPERSONICS: See Ultrasonics
SUPPLIES: See Medical Supplies
SUPPOSITORIES
  rectum lacerated by, [Turell] *136
SUPPURATION: See Abscess; Otitis Media; Ulcers
SUPRACLAVICULAR FOSSA
  evanescent mass in, hydrocele of neck, (reply) [Seed] 776
SUPRARENALS: See Adrenals
SURGEONS: See also Medicine, profession of; Physicians; Surgery
  American College of, (first regional South American Congress, Brazil), 70; (surgical scholarships established by), 539; (A.M.A. resolution on public relations), 839; 840; 841; 842; (cancer diagnosis) [Cameron] 870—C
  fail to cover their scalp hair at operations, [Prioleau] 477—C
  helper: a powerful patented magnet, [Duffy] 1067—C
  International College of, Brazilian section and first Panamerican congress, 70; 1543
  National Convention of (2nd) Colombia, 752
  Royal College of, London, (addition to), 1258; (Queen Elizabeth attended ceremony), 1453
  ship surgeon, work of, 1420—ab
  Travel Club, 341
SURGERY: See also under specific diseases, organs and operations as Cesarean Section; Peptic Ulcer, surgical treatment; Splenectomy; Stomach surgery; Thyroidectomy; Tonsillectomy
